What is to be regarded as a slow pulse? An average of a large number of promiscuous counts would have little value, and the variations in age, sex, position and so on have been sufficiently often stated. A very interesting statement was made by Gros (*Union Med.*, Paris, 1870, p. 658) in regard to the Bretons whom he had the opportunity to ob-

serve in the military hospitals during the Franco-Prussian war. They had habitually their pulses considerably below the average of the rest of France. I have seen a similar statement as to the Central African negroes, but I do not know on what original authority.

Riegel quotes Kaiser as saying that whole families show slow pulse. Russell (*Med. T. and G. J.*, 1877, p. 229) reports the case mentioned to him by Crompton, of a man whose pulse has been notably slow for years, but who has long been an enthusiastic salmon fisherman and sportsman. His son has also a very slow pulse.

For the sake of round numbers we may call 60 the lower limit of the usual normal range which would probably be a little below the correct figure for the greater number of large, strong and healthy males. The upper limit, which would apply more closely to smaller, more excitable, and active persons and to females, might be put in the neighborhood of eighty.

It is usual to report cases of a pulse considerably below this as being found in perfectly healthy persons. There are a few in which it is impossible to dispute this diagnosis, but there are others more numerous, in which careful inquiry or the course of time shows the condition of alleged health to be subject to serious exceptions. In fact, such cases are treated of by Huchard as a separate class of Stokes-Adams disease.

It is customary here to speak of Napoleon I., who is said to have had a pulse of forty and to have been uncomfortable when it rose to sixty. Various authors state different figures, but for the sake of emphasis I mention the lowest. According to Ogle (*Lancet*, Jan. 26, 1897*), who made careful inquiries, there is no record of this pulse, but it is a tradition resting upon the verbal statements of Corvisart.

Dr. O'Meara, Napoleon's physician at St. Helena, records, however, that his circulation was very feeble, rarely exceeding 58 or 60 in a minute and most frequently was 54. The strange thing is to find this spoken of as a normal condition in face of that other tradition resting on the same basis but scouted by many Frenchmen, of epilepsy, and of the facts recorded by many historical writers* of those strange attacks of depression and apathy lasting for some hours, which assailed him on more than one critical occasion. Is it not quite as reasonable, as Ogle suggests, to unite the two symptoms into the well-known group of the permanent slow pulse with syncopal or epileptiform seizures?

Cases of physiological slow pulse are not common. Some which are so designated would be more correctly described as cases which up to the time of report had not shown any other obvious symptoms.

Mr. Mayo (*Land. Med. Gaz.*, Vol. XXII., N. S., p. 232) describes several which are certainly open to but little criticism even if classed as physiological, but which are prudently called by him "compatible either with ordinary length of days, or, at all events, with the continuance of life for an indefinite period."

The first was that of a man, aged 35, rather deli-

*It is more than 15 years since Dr. Ogle's early communications on this subject.

*Dorsey Gardner. *Quatre Bras, Ligny and Waterloo*, 2nd Ed., p. 31-36.

cate, whose pulse for many years was about forty, regular, full and strong. The action of the heart was healthy. He was in perfect health and supposed himself to be as capable of bodily exertion as other persons of the same slight frame as himself.

The next was a clergyman who died at 32 of obstruction of the bowels. He was exceedingly active in mind and body. Hills did not embarrass his breathing in the slightest degree. He frequently, however, like most other excitable persons, had fits of languor and depression. His pulse was regular at 30. When the body was examined, commencing ossification of the aortic valves was found.

In his third case there seemed to have been no connection between the slow pulse and some not very severe ailments. The patient occasionally rode eight miles to market.

Vigouroux (*Gaz. des Hop.*, 1876, p. 788) stated that he had known for five years a laborer whose pulse and heart always beat at the rate of twenty. During this time he never attended him but once, and then for "embarras gastrique." On the day of writing he had seen him in hot weather driving a cart with six oxen, "an exercise which demands a certain amount of health and energy."

There are a very few cases in which an acquired slow pulse seems to have become distinctly physiologic. This is difficult to understand unless we admit that the healthy heart is capable of doing an amount of work greatly in excess of what it is ordinarily called upon to do; that is, that the margin is a very wide one and that the physiologic estimates of the amount of blood pumped by the heart are maximums which very much more than cover the ordinary and necessary work. There is perhaps in such cases some adjustment of the capacity and elasticity of arteries, making in effect a larger reservoir, so that an extremely slow pulse may give a stream sufficiently steady for practical purposes. The case of Dr. Archibald Hewan is an interesting one. His pulse, from overstudy and from gout and rheumatism, gradually fell from 72 to 38, where it remained, but he never had a fainting fit. He was able to climb a mountain some thousands of feet high, his pulse at the top being 40.

Before discussing the mechanism and causes of slow pulse, it is well to mention briefly the principal clinical conditions under which it has been met with. Besides the somewhat doubtful physiological class, we find it in convalescence from many acute diseases, and in the course of some acute diseases, especially acute rheumatism.

Atkinson (*Tr. Assoc. Am. Phys.*, 1891) concludes: "It is evident that bradycardia occurring in acute rheumatism cannot in all cases be considered with the phenomena of convalescence from acute febrile disease as some are disposed to do."

Schuster (*Deutsch. Med. Woch.*, 1896, p. 484) reports the following: A child of 4 went through with articular rheumatism with no indication of heart trouble, but after the acute symptoms had passed and the pulse was of normal frequency, a strong systolic murmur was heard at the apex. When this also was in way of improvement a series of attacks were developed, coming on in the evening after the child had been asleep, in which the pulse, which had been small and arrhythmic, grad-

ually decreased in frequency together with the temperature and the respiration, which also took on the Cheyne-Stokes type. The next morning the child would wake up feeling pretty well. This lasted three weeks, when improvement began and continued until an attack of herpes zoster, when there was a new series. Later still, after renewed improvement, there was a third series less severe and coming in the morning. In a later attack of measles there was no heart disturbance.

The slow pulse of the puerperal condition is probably of the same character. In none of these conditions is it usually extreme nor long continued. In convalescence it usually occurs with a slight fall of temperature below the normal and is simply a part of the general reaction from the fever. Examinations of considerable numbers of puerperal cases seem to show that while the slow pulse under these circumstances has no unfavorable significance it cannot be called exactly physiological, inasmuch as it is not invariable, nor in the majority of cases well marked. Heil (*Arch. f. Gynecol.*, 1898, p. 265); Labousquière (*Ann. de Gynecol. et d'obstetrique*); Grüneisen (*Thesis. Halle, A. S.*, 1898); Varnier (*Ann. de Gynecol. et d'obstet.*, 1899, p. 30).

A large number of poisons, both vegetable and autogenetic, have a marked influence upon the rhythm of the heart. Among these are, of course, digitalis and its congeners, which slow the beats through their excitant action upon the vagus and vasomotor centres, the solanaceous alkaloids which act in the opposite direction by an opposing mechanism, and a considerable number which seem to have a general depressing effect upon the whole cardiac motor mechanism, such as aconite, saponine, muscarine, colchicum, and others. The position of tobacco is interesting and peculiar. It seems sometimes to be the cause of temporary slow pulse, although this is likely to be changed to a very rapid one by a slight exertion, but it has nothing to do with the etiology of the permanent slow pulse. Several of the most typical cases (I and IV and many others) have had nothing to do with tobacco, and in others it has not been used to excess. My friend, Dr. Starbird, the surgeon of the Soldiers' Home at Chelsea, where the principal employment of several hundred inmates is the consumption of tobacco, has for some years been looking in vain for a case of permanent slow pulse to show me.

Peaslee (*N. Y. Med. J.*, vol. 23) speaks of two cases of slow pulse, both attended with occipital pain, which recovered at once on discontinuing the weed. He recalls the fact that when examining recruits during the war he found many young men with slow pulse, who turned out to be cigarmakers. He mentions also, which is interesting as showing the power of psychic action on the rate of the pulse, and also as speaking well for the courage and patriotism of the expectant soldiers, that the pulse invariably rose when they were informed that they were accepted.

Tanquerel des Planches (*Lead Diseases*) states that in 1,217 cases of lead colic observed by him, 678 had a pulse of from thirty to sixty.

Whether the pulse follows the temperature, as it does to some extent *below* the normal, although much more decidedly upward, on account of a di-

rect act on or because some special toxin is formed in febrile conditions is not easy to say: there are reasons for supposing the former.

The relation of temperature to the rapidity of rhythmic action is interestingly shown by the chirping of the tree cricket, which, as was first pointed out by Professor Dolbear (see *American Naturalist*, 1897, p. 970, and 1899, p. 935), follows very closely the temperature of the atmosphere at the rate of four chirps per minute to the degree Fahrenheit.

In some physiological experiments where the heart is cut off as completely as possible from all other influences, one may find a relation between pulse and temperature almost as close as this, but only in a few instances the beat of the human heart does follow the thermometer so closely and accurately (*Journal Boston Soc. Med. Sci.*, Nov. 21, 1899, p. 39). The analogy, however, between the slow and disconsolate chirp of the cricket when "the melancholy days have come," and the reluctant pulse of bradycardia is a striking one, even if not scientifically valuable.

The following case is of more interest as showing some intimate relation or close neighborhood between the pulse regulating and heat regulating centers, a dependence of pulse on temperature:

Nieden (*Tr. Clin. Soc., London*, Vol. VI, p. 75) records the case of a man who fell downstairs in such a way as to strike against a wall at the bottom with his outstretched arms, dislocating, as it was afterwards found, the first dorsal vertebra without fracture, but compression of the cord. There was a complete paralysis of the lower extremities, the chest, and the greater part of the trunk. There was then progressive lowering of the temperature and pulse, consciousness remaining perfect to the time when the pulse was thirty and the temperature 81°. Death took place on the 11th day with a temperature of 80.6°. The most remarkable circumstance about this case in addition to its furnishing the lowest recorded temperature is that there should have been any fall of temperature at all, for although a fall of pulse is usual or at least very common in fractures of the cervical portion of the spine with injury to the cord (see Table 11), the rule is exactly the opposite as regards temperature, which rises often to excess.

Williams and Arnold found in young men, after long and severe exercise (*Marathon Runners*, *Tr. Am. Climatolog. Assoc.*, 1899), that there was a fall of temperature and of tension as shown by the sphygmograph, but a very rapid pulse.

Handfield Jones (*Lancet*, Dec. 30, 1876) gave belladonna to a case with low pulse and temperature without effect upon the pulse but raising the temperature some degrees.

In many cases of bradycardia the temperature is a degree or two below the normal, and this condition is not infrequently accompanied by a subjective sensation of cold.

The combination of a subnormal temperature and a pulse which, if not pathologically slow, is close to the lower limit or normal, seems to be met with in persons who are not absolutely sick, but who are not strong, get easily tired and do not recover rapidly from acute illness.

The pathologically slow pulse seems not infre-

quently to arise from extreme muscular exertion or strain, and even in some cases emotional depression. This effect may be a temporary one or more frequently passing off after a few days, although some cases of the permanent form trace their origin to conditions of this kind.

Observations of very slow pulse have always excited the attention of physicians and the number of recorded cases is very considerable. Taking out the well defined classes which have been spoken of, the remainder still comprises the most interesting and important. I have made a collection of all that I could find presenting a certain train of symptoms and tabulated them on that clinical basis before attempting to attach to them definite pathological conditions. Those in which post mortem examinations were made are in the first two tables. The first and most important group of recorded cases are those of the so-called Stokes-Adams disease or permanent slow pulse with acute exacerbations, attended by vertiginous, syncopal, epileptiform or apoplectiform attacks.

If the names of discoverers or of those who have been the first to describe special diseases are to be attached to them they certainly should be so to what they have described and not to a theoretical pathological condition. Adams and Stokes both described cases exhibiting the group of symptoms which I have taken as a basis for the first table. There are modifications which are undoubtedly closely allied which throw much light on the typical form, in which certain of the phenomena have not reached the same completeness as the others, and again it is not only possible but almost certain that this larger symptomatic group must be broken up on the basis of pathology into smaller ones, but notwithstanding these reservations, it must be admitted that the symptom-complex is a well characterized and distinctly limited one.

In these cases, on the occasion, perhaps, of a sudden attack, an early one of those which later characterize the disease, or perhaps by accident, a pulse is found which is very much below the average in frequency. On recovery it rises in frequency more or less, but still remaining below the average. The figures vary a great deal. In the table first, the larger numbers apply chiefly to the usual condition, that is, between the exacerbations or fits; and the very small ones to severe attacks. The habitual pulse varies considerably from day to day and has been given in detail in some of the reports which I did not think it worth while to reproduce, as the very slow pulse is subject to some of the same influences which change the rate of the normal one. The range of frequency may be seen in the tables. It has been noted, however, in some cases, that posture does not alter the rate so much as in health. Fever, however, increases the rate as in normal conditions. In the case of Mrs. P., reported by me, the pulse is, for the sake of brevity, given in the chart only during several periods of a few days each. In the first, it may be seen that a decided drop in the pulse coincided with a moderate fall of temperature. Whether this was the initial fall I have been unable to ascertain. During the paroxysms the heart may come to an absolute standstill, lasting for as much as a minute, and it

may be as low as four per minute for several successive minutes; six per minute has been counted for an hour (*Kinkead, Dublin J. Med. Sci.*, 1898, p. 4).

The failure of the heart has been observed to precede the nervous symptoms, so that the physician with his finger upon the pulse has been able to predict the onset. An aura of various kinds has been observed in many cases.

Rhythm. Many writers have cautioned against the error of mistaking a slow pulse for a slow beat of the heart and object on this ground to the use of the word bradycardia to describe an infrequent radial pulse. One author goes so far as to make this error cover most of the cases of the class we are considering. While it is, of course, true that such a mistake may be made, I have not found in reading over a good many cases that it often has been; many authors stating that the heart beats were or were not synchronous with the radial pulse and others showing by implication that they were aware of the possibility of error and avoided it. Besides this it seems from what follows, that the error, if it be one, does not materially affect the pathology:

There are certain transition stages between the ordinary rapidity of the pulse and the phenomenally slow ones which are very interesting. It is well in noticing the various changes in rhythm to take as a starting point the slow pulse in which no sign of interpolated beat can be in any way detected, either at the wrist or at the heart. Such a pulse is usually of fair strength, so as to be very distinctly felt and heard. The slowness, or to be strictly accurate, the infrequency, consists not in a general prolongation or proportional drawing out of all the elements of the cardiac cycle, but of a systole as sharp and decisive as the normal and a great prolongation of the diastole. That there is *no* prolongation of the systole it would be hard to say, but it is very evident from sphygmograms that it is not prolonged in proportion to the diastole. A physiological writer, to whom I regret that I cannot now give a more exact reference, has stated that the systole varies in proportion of the square root of the diastole, and most of the sphygmograms look as if they conformed quite nearly to such a ratio. Garrod, however (*Proc. Roy. Soc.*, 1870, p. 351, and 1875, p. 142), says "the length of the interval between commencement of the primary and diastolic rises is constant for any given pulse rate, and varies as the cube root of the pulse rate. Thurston (*Jour. Anat. and Physiol.*, 1876, Vol. X, p. 497) confirms this.

For the proofs of this general statement without mathematical accuracy, I may adduce the observations of many auscultators and many sphygmograms. Those taken in Prentiss' cases and published in the fourth volume of our reports are very characteristic. I have taken others of a similar form in several cases, and they are to be found in the literature nearly all bearing the same marks of an energetic upstroke, (systole) often a plateau, although this is certainly much more marked in some than in others, and a quite rapid decline, without a trace of diastolic, until the level is reached just before the next pulse. When the pulse is very slow (see *Tr. Assoc. Am. Phys.*, 1889, p. 122) the pressure may have reached almost to its minimum

some time before the next stroke. In the middle pulse of the second sphygmogram on that page the descent during the last one-third of the diastole or rest is extremely small.

There are sphygmograms which represent a much more gradual rise in the obliquity of the upstroke, but there is a possibility of instrumental error.

A unique observation is that of Auché and Martin (*Gaz. Hebd.*, 1878, p. 87), who examined by means of the radioscope a man subject to attacks of vertigo, who had habitually a pulse of about 40. They say "the cardiac contraction is brisk and does not last longer than ordinarily. Dilation is rapid, but when it is accomplished the heart rests. During the whole of the long pause ("grand silence") it is impossible to determine the least contraction or auricles or ventricles. There is no abortive systole."

On some sphygmograms interpolated beats may be distinctly marked which from their character and position seem to correspond to ventricular contractions. In a paper by Dr. Putnam (*N. Y. Med. J.*, Sept., 1874), not upon this subject but upon the *pulsus bigeminus* and *trigeminus*, sphygmograms are given where three successive beats grow less and less, so that if such a pulse had been counted only by the strongest pulsations it would have been at the radial only one-third of its true number at the heart.

The occurrence of abortive beats has been long recognized in connection with diseases of the heart other than that we are considering, especially in mitral stenosis, where it is not difficult to account for on mechanical principles. The dropping out of beats appears to be one method of formation of the slow pulse from the normal, the intermediate stages having been observed, as if the heart declined to continue a useless labor; but it is not certain that it is the only one. If such intermediate stages have existed in all cases they have certainly not been observed. Baumgarten (*Tr. Assoc. Am. Phys.*, 1888, p. 236) mentions the case of a young man dying of diphtheritic paralysis of the heart, where the development of a slow pulse of 25 from a frequent and irregular one, was traced as occurring in this way. He goes on to remark that "the very rare pulse of atheroma of the coronary arteries—never quite regular—is undoubtedly of this character." I should doubt if it were always developed in this way, although from the rarity of cases in which the development has been watched from the beginning and also from the possibilities of coronary disease existing beyond the limits usually examined it would be impossible to disprove it from recorded cases. An interesting converse may be found in the action of digitalis. Under the influence of this drug stimulating the vagus, the heart's beats become gradually slower and the tension rises. When overdoses are given and poisoning takes place lesser beats are interpolated and finally a rapid pulse is established.

It does not appear that in the slow pulse at any period of its development, nor in the recovery from this condition, which has been sometimes sudden and sometimes gradual, the interpolated ventricular beats are an essential feature, although they may occur at any stage.

Another set of intermediate pulsations observed

at the heart, and sometimes in the jugulars, but not at the radials, seems to be quite clearly shown to depend upon contractions of the auricles which go no further, and are not, as in the normal condition, followed by contraction of the ventricles. Pouzin (*Thèse de Paris*, 1878) refers the sound to the closure of the aurico-ventricular valves, which are heard separately instead of being merged in the other missing elements of the first sound. They thus mark the time at which a systole should occur but does not. Bristowe (*Lancet*, March, 1885) observed a motion imparted to the stethoscope placed near the base of the heart which was wholly unattended by cardiac sound or pulsation in the arteries.

The tracing of cardiac, radial, carotid and jugular pulsations taken by Vaquez and Bureau (*Mém. Soc. de Biol.*, 1893, p. 170), in a case of slow pulse with cardiac sounds not corresponding to anything at the wrist but attended with jugular pulse, and those of Chauveau (*Rev. de Méd.*, 1885, and *Lyon Médicale*, 1883) seem to put the occasional existence of such purely auricular pulsations beyond a doubt. Stokes describes as a new symptom occurring in one of his cases the pulsation of the jugulars, the number of which was difficult to be established, but was more than double the number of manifest ventricular contractions.

Whether the change from the usual to the slow pulse takes place by the dropping of beats, first a partial failure of the ventricular, then the total, and at last of the auricular, is not certain. Comparatively few cases have been observed in their formative stage, but in some it has appeared that this succession has been observed. In others, however, there is no reason to suppose that a simple elongation of the interval should not have occurred just as happens when a very frequent febrile pulse drops down to normal.

In many cases the first observations made, some of them at an early stage, make no mention of intermediate weak beats.

The nervous symptoms of the paroxysms vary a good deal in form and severity. They do not always preserve the same type even throughout the same case, varying from simple vertigo to complete loss of consciousness with convulsions. In a few cases they have been described as epileptic instead of epileptiform, and in others, notably the original one of Adams, as "apoplecticiform," with the remark that they are not followed by paralysis. Different forms do not seem to be attached to any special train of cardiac symptoms or cardiac conditions, nor can the prognosis be very accurately based upon them, as there have been instances of permanent slow pulse where the only representatives of the paroxysms, although genuine, have been so slight as to attract little attention and yet the patient has died suddenly in another.

Dyspnea accompanies many attacks, but is not so invariable a symptom as we should expect when the cardiac function is so extremely depressed. The respiration, except, of course, in the cases where convulsions take place, is more likely to be quickened than slowed to correspond with the heart.

The paleness of the face which ushers in the attack has been mentioned in many histories.

The usual explanation of the nervous phenomena

that they depend upon an anemia of the brain more or less complete and varying somewhat in its local distribution, would account satisfactorily for the differing forms. The dyspnea, however, is very likely to be of the same kind and origin which is found in the more common kinds of cardiac disease, and it is possible that on this account the number of cases included in the first table of the most typical form of Stokes-Adams disease ought to be somewhat diminished; but the line would be a difficult one to draw with absolute precision.

The number of cases which I have included in the first table on the basis of the symptoms and in which an autopsy has been made is thirty-four.

Naturally the records vary widely in completeness and possibly also in trustworthiness, but in very few of them has there been any satisfactory examination of what we cannot help regarding as a very important, if not essential point, that is the nervous supply of the heart, especially the sympathetic cords and the intrinsic ganglia of the heart.

To any one who has sought for the ganglia among the cardiac plexuses and in the heart itself it is not necessary to suggest a reason why they have not been more frequently examined with modern histological methods. Whether the fate of Dr. Robert Lee, who got into much trouble with the Royal Society for his too abundant discoveries of ganglionic nerves, has had any discouraging effect on would-be investigators, may well be doubted. In our more liberal times anatomical rather than ethical obstacles have probably been more effectual in keeping these structures out of the routine of the ordinary post mortem, and as typical cases are among the rarities of clinical observation the chances of the right case falling into the hands of the zealous histologist are small. These structures are far from easy to find except by the tedious process of imbedding and cutting of serial sections from the regions where they are likely to be found and many sections may be examined without finding any.

They are situated in the septum of the auricles in the triangular space bounded on each side by the diverging walls of muscle, and above by the pericardium, immediately beneath which latter they lie, being specially grouped above the foramen ovale, and more posteriorly where the septum comes down to the sulcus between the auricles and ventricles. They are said to extend beyond these regions, especially along the sulcus, and probably do so in a scattered way, but practically these are the best regions to search. They are not to be found at all below the transverse sulcus in man, but are described by some authors* as occurring over the upper third or two-thirds of the ventricle in some animals. For examination in the fresh condition they may be found by dissecting out from the appropriate localities pieces of nerve and tearing them apart with needles. This is not a very certain method, as many pieces may be examined without success, but occasionally one may get in this way a very satisfactory specimen. I have once in a very emaciated heart found just beneath the pericardium lying over the top of the auricle a couple of small ganglia the size of very small pinheads.

*Katz in Beck (*Chl. Med. Wiss.*, 1897.)

The structure of these ganglia is that of sympathetic ganglia in general, consisting of from one (on section) cell to forty of fifty or more with fibres of both kinds, white and grey. The cells are enclosed each in its capsule, consisting of many small nucleated cells. The nerve cells have a very finely granular or rather semiopaque parenchyma less pigmented than that of many sympathetic ganglia, and a large nucleus. The ganglia resist with considerable tenacity the process of dilaceration. These ganglia have been investigated by a considerable number of histologists in various diseases, but among them there have been few if any of the kind we are considering. They are as follows:

Romberg and His, *Prager Med. Woch.*, 1890, p. 331. Embryological. Cardiac ganglia are offshoots from the sympathetic and remain connected with it; hence are only sensitive.

Dogiel (*Arch. Mikr. Anat. XI and XX*) Anatomical.

Schwarz (*Berl. Klin. Woch.*, 1898) showed specimens of ganglia. They are few in the mammalian heart, situated superficially in and above the auriculo-ventricular sulcus. They lie mostly in the neighborhood of the mitral valve. They should not be confounded with the "Mast-cells," which are found all over the surface of the ventricles and which have given rise to some of the mistakes. Lübmoff (*Virch. Arch.*, 61, p. 145). Histology; many drawings. Pathological changes consist in thickening and degeneration of the cell capsules. Thickening, amyloid degeneration, and metastases (micrococci) in the vessels; and degenerative changes in the nerve cells. The latter in adults always contain pigment.

Ivanowsky, *Rudnoff's Journal* (Russian)—abstract by Putjatin (v. i.). Observations on spotted typhus. Changes chiefly parenchymatous, but capsular endothelium often swollen. He explains by these changes the heart paralysis which caused death in the early periods of typhus.

Putjatin (*Virch. Arch.*, 74, p. 461) examined ganglia in three groups of cases. In the first two groups there were serious organic changes in the heart. In the third the changes were dependent on constitutional disturbances. Fibrous intergrowth in ganglia. Degenerative changes in protoplasm.

Uskow (*Virch. Arch.*, 91, p. 453). Changes in the heart ganglia connected with hypertrophy of muscle. Chiefly in the medullated fibres, which lose their myelin sheaths and show the process of proliferation of the nuclei. The visible changes in cells are limited to proliferation of the nuclei capsules. In certain acute diseases occur the changes pass on to parenchymatous inflammation. In two children with diphtheria he found no changes.

(To be Continued.)

Spontaneous Expulsion of Large Biliary Calculi.—Troisier reports two such cases in the *Bulletins et Memoires de la Société Medicale des Hôpitaux de Paris*, (May 30, 1901, No. 18). In the first patient, a woman of 60, who had never had hepatic colic or jaundice, the symptoms of acute intestinal obstruction appeared, and lasted about twelve hours, when a gallstone, weighing 7 gm., was passed with a normal movement of the bowels. There have been no symptoms in the three years which have gone by since. In the second case, a calculus which weighed 8.5 gm. was passed without any symptoms before or since. [M. O.]

PROGRESSIVE HARDNESS OF HEARING AND ITS ARREST BY SURGICAL REMOVAL OF THE INCUS.

By CHARLES H. BURNETT, M. D.,

of Philadelphia.

Clinical Professor of Otology in the Woman's Medical College of Pennsylvania, Aural Surgeon, Presbyterian Hospital, etc., Philadelphia.

Progressive hardness of hearing and its accompanying symptoms, tinnitus aurium and vertigo, are due to disease in the middle ear. This aural malady has generally been supposed to be due to a chronic catarrhal inflammation in the mucous membrane of the middle ear, and has been sometimes denominated "dry catarrh of the middle ear." There is, of course, such a disease as catarrhal deafness that gets better or well after the catarrhal symptoms are relieved. In many cases of hardness of hearing, however, even with catarrhal symptoms in the ear, nose and nasopharynx, after the latter are relieved, the ear symptoms remain unchanged or grow worse. Such is the condition characterizing progressive hardness of hearing, or so-called chronic catarrh of the middle ear. The catarrhal symptoms in such cases are not to be regarded as primary and causative, but as secondary and resultant, or accessory and complicating. The catarrhal symptoms may be said to be superposed upon the affected tissues of the middle ear, the pathogenesis of the latter disease not being positively demonstrable. Progressive hardness of hearing must be regarded as an "affection of the nerves supplying the middle ear and correlated structures." (Weber-Liel, Berlin, 1873.) The majority of the symptoms indicate that neuroses of the trigeminus play the greatest part in the causation of this form of ear disease, though disturbances in the sympathetic innervation have much to answer for in the development of progressive deafness. Many of the phenomena of this disease indicate furthermore that complex disturbances in the correlated areas of the vagus, glossopharyngeus, facial, auricularis magnus and spinal accessory nerves also have much to do in the development of the aural malady under consideration. Hence many aural neuroses, i. e., neuroses in the tract of the middle ear nerves, occur not as such, alone, but must be regarded as standing in the closest relation to simultaneous and similar ones in the structures of the nasopharynx, fauces, larynx, and the opposite fellow ear. In the latter instance is seen an example of cross influence of one ear upon the other.

Subjective Symptoms.—From such nervous lesions are developed a large series of the most dangerously insidious and progressive forms of deafness, tinnitus aurium and ear vertigo or so-called Ménière's symptoms. Hardness of hearing and deafness are the prominent and earliest subjective symptoms in this disease, tinnitus aurium being the next, and aural vertigo the last symptom in the distressing list.

Objective Symptoms.—Among objective symptoms, the most prominent are the changes in the position and appearance of the membrana tympani and ossicles of hearing. The drumhead becomes opaque, lusterless and retracted from contraction of the tensor tympani muscle. The malleus handle

instead of being nearly vertical in position is drawn backward and upward and appears foreshortened. In this process of retraction the membrana tympani is brought nearer the inner wall of the drum cavity, and in many instances the promontory of the cochlea, and the incus-stapes joint become visible through the membrana. These are the most important of the physical symptoms of progressive hardness of hearing, and in them can be seen the mechanism of progressive deafness.

The Ossicles.—The immediate result of retraction of the membrane and malleus is retraction of the incus and stapes, with impaction of the latter bonelet in the oval window. Impaction of the stapes is all the more readily produced if the stapedius muscle is weakened by a lesion of the facial nerve from which the muscle obtains innervation. In a normal ear impaction of the stapes in the oval window and consequent compression of the labyrinth fluid in the vestibule receives compensation by an outward movement of the membrane of the round window. But in progressive hardness of hearing, changes occur in the membrane of the round window which render it stiff and unyielding to intra-labyrinth pressure, and its compensatory bulging outward toward the tympanic cavity is hindered or destroyed. Hence impaction of the stapes in progressive deafness is followed by disastrous pressure on the terminals of the auditory nerve in all parts of the labyrinth, resulting in deafness, tinnitus, and at last, in some instances, ear vertigo.

This form of hardness of hearing generally begins in one ear, in which it progresses slowly for a year or more, the opposite ear remaining normal. Suddenly the patient is surprised that the good ear is failing in hearing, and progressing more rapidly towards deafness than the ear first attacked. It is not unusual to discover that when the patient presents himself for treatment it is because, the ear so long the better one, has become the worse, and that the ear first attacked, though hard of hearing, is at last the better one. This unfortunate result is doubtless due to the synergetic, or "cross" influence of one ear upon the other. Cross influence of one organ or limb on one side of the body upon its fellow on the opposite side is not yet fully explained, but its existence is doubted by few. The ears are to be considered correlated areas quite as much as the ear and the nearer half of the soft palate from which the tensor tympani muscle originates. Nearly always in a case of progressive hardness of hearing a partial paresis occurs in the half of the velum nearer the more affected ear, in consequence of which the opposite half of the velum draws the uvula towards the better ear. The preponderance in traction on the part of the stronger side of the velum induces muscular imbalance in the muscular structures of both middle ears. It is thus shown that the two ears must be regarded as very closely correlated areas, and that very readily a cross influence, or a synergy either for good or bad, passes from one to the other. The fact that first one ear and then the other, in the course of a year or two, is affected by progressive deafness, seems to indicate that the implication of the second ear is dependent upon the cross influence of the ear first diseased. This view is strengthened by the deterrent

and prophylactic effect of the surgical treatment, as will be shown later. Every aurist knows that the chief causative factor in the phenomena of this disease is the undue contraction of the tensor tympani as evidenced by the great retraction of the membrana tympani and the chain of ossicles. Sooner or later this disordered state of the tensor tympani muscle, and the chain of conducting bonelets is imitated by the opposite ear. Many years ago (1888) I demonstrated that by the liberation of the impacted stapes, through removal of the incus, and consequent interruption of the retractive power of the tensor tympani, tinnitus aurium and ear vertigo are relieved. This operation, however improved the hearing, either not at all or only a very little, but I observed that it did not diminish the hearing in the ear operated upon, and that the progress of the deafness was arrested in it. As I have been able to observe closely and protractedly during the past 13 years some of the cases first operated upon, I have noted that in the opposite ear if already affected, the progressive hardness of hearing has been in some instances arrested and the hearing improved. The only explanation of this result I can offer is that the contraction of the tensor tympani, spasmodic in character, being overcome by the removal of the incus in one ear, the synergetic contraction of the tensor in the opposite ear, induced by cross influence of the more diseased organ, was also overcome by a beneficial cross influence emanating from the operation in the diseased ear. This improved condition of one ear resulting from improvement in the condition of the opposite one, is quite as comprehensible as the improved muscular condition of the left arm observed to follow the development of the right. (Scripture.) It was also observed that if the fellow ear was entirely unaffected by symptoms of progressive deafness at the time of the operation, it showed no tendency to become thus diseased, demonstrating a prophylactic effect of the operation in the affected ear, upon the unaffected one.

Cases. The first case to be observed in this way was that of a woman, 31 years old at the time of the operation in May, 1888, 13 years ago. The tinnitus and vertigo were promptly relieved by the operation upon the left ear. The hearing 6 in. for the tuning fork was unaffected by the operation. The right ear has remained a good ear to the present time, notwithstanding chronic rhinitis and some general ill health on the part of the patient.

A second case, which I have been able to watch for 10 years, since March 5th, 1891, is that of a woman 20 years old at the time of the operation. In this instance the hearing was greatly improved by the operation from 6 inches to four feet, and the opposite ear has never shown any symptoms of progressive deafness, though the patient has some chronic hypertrophic nasal catarrh, and has passed through one pregnancy since the operation.

A third case kept under observation, is that of a woman of 30 at the time of the operation, November 21st, 1892. There was a slight improvement in hearing brought about in the left ear by the removal of the incus. Though her general health has not been good, the ear not operated upon has shown no symptoms of progressive deafness.

A fourth case kept under observation is that of a young man 22 years old at the time of the removal of the incus, December 12th, 1892. In this instance the incus was removed from the left ear, resulting in improvement in hearing, from 12 inches to four feet for isolated words. The right ear also showed signs of progressive deafness, the hearing in it being from 2 to 3 feet for isolated words. The hearing in the left ear was maintained at four feet, and the progress of the deafness in the opposite ear was ar-

rested by the operation. This fortunate condition of hearing continued until the untimely death of the patient in 1899.

This case I have reported, American Otological Society, July 19, 1898, as an example of the deterrent effect of incudectomy upon progressive deafness, not only in the ear operated upon, but upon the opposite ear. In the other cases reported in this article the prophylactic action on the unaffected ear is also demonstrated.

The sooner the operation is performed in the affected ear, or in the more affected ear, if both ears are implicated when first seen by the aurist, the better the results. Every aurist knows that the tendency in progressive deafness is towards a fall in the hearing to a very low point; first in one ear and then in the other. Let perfect hearing be represented by 100. If a patient presents himself with a hearing distance of 100 in one ear, and 75 in the other, it is advisable to operate at once on the defective ear even if the hearing in it fall say to 60, because the effect of the operation on the good ear will be to maintain it at 100, so that the equation of hearing in the two ears will become 100, but be maintained at that point by the deterrent effect of the operation on the diseased ear. If this operation is not performed the hearing will sink in both ears to a low degree. In other words it is better to sacrifice some hearing in the affected ear, but preserve a good total of hearing in both ears, than allow both to sink to low points, as is the tendency in progressive deafness. In any instance of progressive deafness, especially if the hearing be defective in both ears, and tinnitus aurium be present in the more defective ear, incudectomy is indicated in the latter, as offering the only means of relief of deafness and tinnitus, and prophylaxis of ear vertigo in the ear operated upon. It will also arrest the progress of the disease in the better though defective ear, and ward off tinnitus and other conditions in it conducive to ear vertigo.

Operation.—The patient should be etherized (local anesthesia by cocaine being both inefficient and toxic according to my experience) and the external auditory canal and the membrana sterilized by a solution of mercuric bichlorid (1 to 5000) or one of formalin (1 to 1000), or with alcohol. Then the auditory canal and membrana tympani should be illuminated by means of an electric light held on the forehead and run by a small portable storage battery, made for the purpose of clinical illumination.

When the membrana is intact, as it is in a case of chronic progressive deafness, the initial incision is made with a delicate knife, beginning close behind the short process of the malleus and following closely the periphery backwards and downwards until reaching a point below the line drawn horizontally through the umbo of the membrana. This cut is followed by little or no bleeding as a rule. The flap thus made should be pushed inward towards the promontory by means of a probe armed with a small dossil of sterilized cotton. If there be no bleeding the incus-stapes joint is seen as soon as the flap of the membrana is pushed aside. If there be bleeding it must be mopped away with sterilized mops on a cotton holder.

The incus being now in plain sight, it should be gently disarticulated from the stapes by drawing the former outwards and downwards by means of an incus-hook knife passed behind its long limb. When this is done the long limb of the incus should be grasped by special forceps and drawn very cautiously downward and outward into the auditory canal and then removed entirely from the ear. When this is accomplished the operation is finished. The slight bleeding that sometimes occurs in these cases requires no attention. The rest of the conductors of sound are left intact. The meatus should be stopped

with sterilized cotton and the ear let alone for 24 or even 48 hours, unless the cotton in the meatus gets moist with blood or serum. If this occur the cotton should be removed and dry cotton inserted. There is to be no after-treatment in such cases, as all is accomplished when the incus is removed. As a rule there is no reaction in these cases, and the wound in the membrana heals by first intention. Sometimes a slight reaction has occurred, shown by a little pain and some mucopurulent discharge. But this is healed in a few days by simply mopping the ear with sterilized cotton and a solution of formalin (1 to 1000) and such reaction has never had any bad effect upon the result of the removal of the incus in checking the progress of the deafness. A serious reaction I have never encountered after any of my operations for incudectomy, and the patient is never obliged to remain in his room for more than twenty-four hours.

It must be borne in mind that between 1888 and 1892 I had operated upon only 25 cases of progressive hardness of hearing, and that of these, few could be kept under my continuous observation. I soon discovered, and have long taught, that incudectomy was an efficient mode of breaking the retractive force of the tensor tympani muscle, liberating the stapes impacted in the oval window, and thus relieving tinnitus aurium and ear vertigo. After patiently watching some of the cases operated upon from ten to thirteen years ago, I now feel justified in my conclusions that the operation of incudectomy also arrests progressive deafness, not only in the ear operated upon, but in the opposite ear if it has appeared there, or acts as a prophylactic in the better ear if it be not yet affected. Since 1892 I have operated upon 53 cases of progressive hardness of hearing in order to break the retractive force of the tensor tympani upon the chain of auditory ossicles; four times by resection of the long limb of the incus, eight times by tenotomy of the tensor tympani, and 41 times by incudectomy, the last named method being the preferable one. The results of the operations in these 53 more recent cases it is purposed to present in future communications.

THE DIFFICULTIES ATTENDANT UPON THE PROPER TREATMENT OF DISEASES OF THE EAR IN DISPENSARY PRACTICE.*

By FRANCIS R. PACKARD, M. D.

of Philadelphia.

Professor of Diseases of the Ear in the Philadelphia Polytechnic, and
Aurist to the Out-Patient Department of the Pennsylvania Hospital.

I have been led to make the following brief presentation of facts because I believe it to be the duty of those who have charge of the otological departments of our hospitals to do all in their power to render their dispensary services of the greatest possible utility to the patients, the hospital and to their own scientific interests. I hope to arouse interest and discussion of the matter on the part of hospital boards of management as well as of physicians with a view to the betterment of the conditions I mention, and I think the same statements apply largely

*Read by title at the meeting of the American Laryngological, Rhinological and Otological Society, New York, 1901.

to other dispensaries as well as those for the treatment of diseases of the ear. All of us are familiar with the fact that the cases of aural diseases which we treat in our offices respond much more readily to treatment and are cured or relieved in much larger proportion than are those seen in dispensary practice. I have thought carefully over the reasons for this and have discussed them with a number of others who are engaged in hospital work, and I now present some of the conclusions at which I have arrived.

First, as regards the social condition of our hospital clientele. Of course, this varies greatly in different hospitals; in one consisting of respectable, hard-working people; in another made up largely of foreigners; and in yet another of the colored race. In most large city hospitals it consists of a mingling of various races and all sorts and conditions of men.

In the Pennsylvania Hospital, the patients in the ear dispensary consist largely of Russian Jews, Italians, and Slavs. These people as a rule do not understand English, are filthy in their habits, living in the most squalid conditions. It is impossible to even make them understand directions, much less to make them carry such orders out, as regards return visits and home treatment. Very few of the foreign patients possess enough sense to bring an interpreter with them, and if you do procure some one who can talk to them he usually understands very little more of your instructions than the patients themselves. The class of patients who suffer most from this condition are the children with suppurative ears. The parents cannot be depended upon to properly cleanse the ear of the ever accumulating discharge, or to bring the child back to the hospital on the days designated for its treatment. Such neglect results in filthy, eczematous conditions in the external ear, in mastoid involvement, or in brain abscess. Frequently I have sent children into the hospital, where a few days proper treatment has terminated in recovery what would otherwise in all probability have resulted in a very chronic, possibly fatal, condition, whom I had reason to suppose would be thus neglected by their parents. Many times these people through ignorance will not consent to leave their children in the hospital even when they are very sick. Consent to operations, even as minor as the removal of polypi, or the evacuation of an abscess over the mastoid, is frequently refused and the condition of the ear thereby greatly aggravated.

Secondly, the difficulty of properly examining and treating the patients, because of the overcrowding of most dispensaries, is to my mind a very real evil. What aurist would venture in his private practice to treat patients, taking them just as they come, new and old cases, serious and trivial, at the rate at which dispensary patients are generally rushed through? Many of the cases present features of much interest over which one desires, and ought to linger, but there is always the ever pressing throng clamorous for their turns. The examination with the speculum is usually all that can be satisfactorily made, the functional examination requiring time and quiet, which are but too seldom procurable, and yet, as Dr. Randall (*Journ.*

American Med. Ass'n, March 23, 1901) has recently emphasized, how essential such examinations are. I cannot but think that one reason why such functional examination is often neglected is because we have become habituated to its neglect in our dispensary work. If useful with our private patients it is surely just as valuable with those we see in dispensaries.

After examination comes treatment, and here the time limit again operates to the disfavor of our patients. A case of impacted cerumen may require ten or fifteen minutes; the proper cleansing of a suppurating ear, to be done with thoroughness and with comfort to the patient, may require fifteen or twenty minutes. A few cases of this kind will consume time to such an extent that the rest of the patients must be hurried through at breakneck speed.

Thirdly, how difficult and almost impossible it is to keep records of dispensary cases. The first visit is always, at our dispensary, made a matter of careful record, but after that, unless one of us is particularly interested in following up some particular case, I am afraid the record is usually left blank. How utterly worthless dispensary records are! Partly on account of failure to note progress, partly because practically no ultimate results can be noted, the patients disappearing from observation as soon as they are cured, or if not cured, because they are discouraged, and, treatment costing them nothing, they want to make a change.

How shall we overcome these difficulties? The question of hospital management so that there shall be the greatest amount of good accomplished with the least waste of money so charitably given for the relief of the sick poor, is a very deep one and may be considered as beyond the province of the present paper, but it seems to the writer that no province of hospital work has been more neglected as regards its business management, and stands in more urgent need of reform than the dispensary service, and to this lack of attention is to be attributed its comparative failure. The managers and superintendents of hospitals, as a rule, pay close attention to the condition of the buildings, to the average cost of maintenance of patients, the expenses of the drug department, and to the proper performance of their duties by the physicians and surgeons in the wards. Great attention is paid to the admittance only of proper cases to the wards. Efforts are made to have a sufficient surgical armamentarium in the operating rooms.

Now let us turn to the condition of affairs in the average dispensary.

We have heard lately a great deal of talk about dispensary abuse by patients who are able and should be made to pay for the services of a physician. This talk is largely based on the injury supposed to be inflicted upon the doctor. The truth is that, as a rule, the doctor suffers less than anyone from this really grave abuse. The charitable people who have given their money to relieve the sick poor may here behold their funds misappropriated. By adding to the number of patients to be treated these "beats" take up time which should be given to the suitable objects of charity; by adding to the expense of the dispensary they lessen its power to en-

large its means of doing good. It is this detestable class of patients who always insolently expect more trouble to be taken with them and more time given to them than can be given to the truly poor. To a great extent this evil could be remedied if in every hospital a dispensary clerk was maintained, whose duty it should be to issue cards to suitable persons for dispensary treatment. If the person applying for treatment appeared as though he ought to be able to pay, a minute inquiry should be made into his circumstances, and if not an object of charity he should be refused treatment. The Eye, Ear, Nose and Throat Hospital of New Orleans has a registration clerk, and from its last report I quote the following paragraph:

"Forty-two persons acknowledged their ability to pay, and were denied admission by the clerk at the registration desk. Besides these, there were 57 cards withdrawn by the examining surgeons; 37 in the eye department and 20 in the ear, nose and throat department, making a total of 99 applicants who were discovered in the act of imposing, intentionally or not, on a charity founded for the poor only." Probably many more patients who could pay were deterred from applying by the mere knowledge that their circumstances would be inquired into.

A man of discretion in such a position would possibly save his salary to the hospital in the course of a year, and his labors would be of the most direct benefit to both patients and doctors.

Almost all dispensaries are cramped for room and consequently seriously hampered in their efficiency. Every otological dispensary should consist of at least three rooms, a waiting-room, a quiet room in which new patients could be studied and in which functional examinations could be properly made, and a room for the treatment of routine cases. No otological dispensary should ever be run unless equipped with sets of tuning-forks and other instruments necessary for the most accurate diagnosis. Many otological dispensaries possess but one tuning-fork, and that tuning-fork is rarely used because of lack of time, and the noises which usually accompany the work in a busy dispensary. How rarely are the Galton whistle or the acoumeter to be found among a dispensary's equipment!

It is but right that we whose daily work lies in dispensaries and who must be struck with the miserable waste of money and effort which is daily taking place in them, should be the first to point to the existence of such evils in the dispensary system. How else can we hope to impress superintendents, who, in their efforts to fulfil the wishes of the managers, must devote their time and labor to the hospital in distinction to its dispensaries, or managers, who, perhaps, never visit the dispensaries during the hours when work is being carried on in them, and who often really know but little of what goes on in the hospital, save what can be seen from the books of the superintendent, and by their walks of inspection through the buildings and wards. The managers are apt to base their ideas of the work of the dispensaries on the statistics of patients. If these show, as they usually do, a steady increase in number, the managers point with pride to the increased usefulness of the dispensaries, little think-

ing that this increase has in reality greatly diminished the ability of the dispensary to do good.

Finally, it seems to me incumbent on all physicians who work in the special dispensaries, whether for the ear, nose and throat, or eye, in which these abuses are most apparent, to lose no opportunity to insist that the dispensary work be as carefully provided for as the work done in the wards, that the number of cases handled be restricted to those which can be properly studied and treated, and that every dispensary contain an up-to-date complete armamentarium. Only by so doing can we bring the dispensaries up to a level upon which they will perform scientific work, and at the same time benefit those worthy of charity. A hospital which wishes its work to result in the greatest amount of benefit to those worthy of its charity should see that the agents selected to carry out its work are given every facility to properly perform their duties, and then should see that those duties are properly performed. At the present time I am convinced that in most dispensaries there is a large absolute waste of clinical material for scientific study. Medicine and surgery have in recent years made such enormous advances largely because the cases in the wards of hospitals have been so thoroughly utilized for purposes of study. In the modern dispensary, however, entirely too much attention is paid to securing an enormous attendance of patients and then rushing through their routine treatment, without stopping to study individual cases, not only at their first, but at their subsequent visits.

MENIERE'S DISEASE.*

By S. MacCUEN SMITH, M. D.,
of Philadelphia.

Clinical Professor of Otology, Jefferson Medical College, Otologist and Laryngologist to Germantown Hospital, Philadelphia.

In accepting an invitation to contribute a brief paper on this subject, the writer does so without the expectation of adding anything new to our knowledge of the subject, but with the hope that the discussion which follows may throw some light upon an affliction the exact nature of which is so little known. Since Paul Ménière read his notable paper before the Academy of Medicine at Paris in 1801, the disease which still bears his name has been the subject of much contention. Although Ménière, in his famous case, showed conclusively by post-mortem demonstration that the semicircular canals were filled with clotted blood which encroached to some extent upon the cavity of the vestibule, there has always been a tendency, apparent even at this late day, to make use of, or apply the term Ménière's Disease to almost all severe aural disturbances characterized by vertigo, deafness, etc. This misunderstanding or misapplication of the disease outlined by Ménière has led to much confusion as to the actual pathology of the lesion. Manifestly, if the term Ménière's disease means anything, it must be restricted to that complexity of symptoms at present recognized as the outcome of what is termed apoplexy of the labyrinth. Furthermore, this laby-

*Read before the American Laryngological, Rhinological and Otological Society at its seventh annual meeting, held in the New York Academy of Medicine, May 23, 25, 1901.

rinthine hemorrhage should be primary in its inception, and occur suddenly in a subject free from previous ear trouble, and enjoying excellent general health at the time of the attack. If then, gentlemen, such restrictions are to be placed upon this pathologic entity, how very uncommon must be a true case of Ménière's disease.

Personally, the writer has long since felt that the so-called Ménière's disease is of most exceptional rarity; furthermore, if we exclude previous systemic illness as a causative factor, this disease must, with few exceptions, be regarded, from an etiologic standpoint, as the result of traumatism; and who to-day would venture a definite diagnosis in most lesions involving the base of the skull?

Since the publication of Flourens' experiments on the semicircular canals of pigeons, it has generally been accepted that in the semicircular canals we have the peripheral organs for the maintenance of equilibrium. On the other hand, "Steiner has found that, when the membranous canals of sharks have been excised, and the animals then returned to the water, there is no disturbance of locomotion. If, however, the auditory nerve be stretched, or the ossicles pulled upon, locomotion is interfered with. Similar experiments were confirmed in lizards and frogs, which would tend to show that the canals are not necessarily associated with equilibrium, and that the disturbance of locomotion has probably a central cause in the medulla." Furthermore, Magendie and Cuvier have shown that the same results may be induced by division of the transverse fibres of the pons varolii, or of the fibres running from the cerebellum to the corpora quadrigemina, or of those passing from the cerebellum to the spinal cord.

Baginsky asserts that the semicircular canals have no part in the maintenance of equilibrium; as the entire labyrinth of a dog may be destroyed without the appearance of any disturbance of this nature. Gellé speaks of Ménière's symptoms as occurring, or likely to occur, in diseases of the middle ear, in hemorrhage into the labyrinth, in hyperemia of the labyrinth, in anemia of the labyrinth, in labyrinthitis, in hyperesthesia of the labyrinth, in reflex labyrinthine vertigo and toxemias.

The lamented Gruber, to whom the writer is indebted for many of his references, affirms that "it is now certain that an exaggerated intralabyrinthine pressure first of all takes effect upon the perilymph, and is then transmitted through the aqueductus cochleae to the subarachnoid space, thereby inducing the results under discussion, if this action takes place with sufficient rapidity. The pressure may always be moderated to a certain degree, since the direction in which the aqueductus cochleae opens into the subarachnoid space is not the most effective one. It is, however, quite otherwise with the aqueductus vestibuli; for if the pressure on the sacculus becomes excessive, the endolymph can give way directly through this channel towards the cranial cavity, and if the recessus Cotugnii be largely developed, it will become distended to a corresponding extent, and thus exercise a more considerable pressure upon the centre of statical equilibrium, the cerebellum, evoking symptoms of vertigo, etc. If, on the other hand, the recessus Cotugnii be but slightly developed the phenomena in question may then be quite absent. It should likewise not be

forgotten that the pressure brought to bear by the perilymph through the aqueductus cochleae upon the extended area of the subarachnoid space is proportionately greatly lessened in its effect, a condition which does not exist in respect of the closed recessus Cotugnii."

Since, then, it seems to be definitely shown that Ménière's symptoms do not arise exclusively from a single disease of the labyrinth, but are more or less prominent in traumatisms and various other pathological changes involving the ear and adjacent structures, would not the cause of otology be best served, and much confusion averted, by adopting a nomenclature defining as far as possible the location and nature of the various affections of the internal ear without consideration of Ménière's disease. It is desirable, of course, that *Ménière's symptoms* should have proper recognition, but the term *Ménière's disease* cannot be used as at present understood without perpetuating, and probably multiplying, the confusion already extant.

In many instances an injury to the brain substance proper, rather than to the semicircular canals, is unquestionably the cause of an inability to move in a forward direction. In common with the writer, many of those present have doubtless witnessed the ability of rabbits to run at a rapid pace in a small circle after receiving a gun-shot wound of the head. Dalby's experience in this direction has shown conclusively that the wound did not in any way injure the ear, a subsequent examination disclosing the shot located in the *cerebellum*. Dalby has suggested the term auditory vertigo, to distinguish between vertigo due to lesions of the ear and that arising from other causes. This, however, seems objectionable, as the term is too general in meaning, not defining any particular disease, nor the exact portion of the ear involved.

"Tympanic vertigo," as suggested by C. H. Burnett, is an efficient and expressive term to distinguish between vertigo due to middle ear disease or disturbance of intratympanic pressure, and that involving other parts of the ear or neighboring structures. The writer is firmly of the opinion that too little importance has been given to the diseases involving organs more or less remote from the ear, which, however, play an important part in the secondary development of many pathological changes in the organ of hearing. Just as an intractable cough at times develops during the course of certain diseases of the kidneys, so also has the writer observed aural manifestations in cases suffering from nephritis, which he hopes in the near future to make the subject of a separate paper. To carry this thought a step further; is it not reasonable to presume that the benefit we sometimes secure by the use of quinine for the relief of tinnitus, is due to the fact that the tinnitus was the result of malaria and consequent anemia of the labyrinth; the quinine not only exerting its specific action on the general disease, but also relieving the labyrinthine ischemia, a condition from which most patients so afflicted probably do suffer.

The element of time and rest which is usually self-enforced, are the two most prominent factors in the treatment of a real case of Ménière's disease; and yet, counter-irritation, together with the

use of the iodides, bromides, etc., probably have some virtue, and should therefore be employed.

The writer believes that most diseases of the internal ear are secondary either to some tympanic or to some systemic trouble (excluding traumatism), which must necessarily be carefully sought after and so far as possible corrected, while the local manifestations are being dealt with as the symptoms demand.

It is not the purpose of this paper to enter into a discussion of the treatment of the various diseases involving the internal ear. However, we wish to commend the employment of the subcutaneous injection of pilocarpin, as suggested by Politzer, in syphilitic affections complicating the ear. Furthermore, we desire to call particular attention to the virtues of Zittmann's decoction in cases where the use of mercury is indicated, in lesions of the ear, nose or throat. The writer also desires to endorse the removal of the incus, in selected cases for the relief of tinnitus and vertigo, as suggested by Burnett.

A NOSOLOGICAL STUDY, FROM A CLINICAL STAND- POINT, OF CERTAIN MANIFESTATIONS AC- COMPANYING AND FOLLOWING MALARIA.

By G. W. PENN, M. D.,
of Humboldt, Tenn.

With the history of this important subject in its ordinary forms, the profession is familiar since the work of Laveran, in 1880, and since confirmed by Marchiafava, Celli and others. The discovery of the hematozoon of malaria has, of course, done much toward bringing order out of the chaos of Southern fevers. Vidal's blood test and Ehrlich's diazo-reaction have still further straightened the tangled nosological skein over which so many brilliant men, both from a laboratory and a clinical standpoint, have spent so much time. And yet the fevers of tropic and temperate climates are still unclassified! Ever since Woodward's attempted explanation of the febrile phenomena he found south, as a hybrid fever, under the name typho-malarial, there have been numerous theories offered only to be exploded in the light of further research.

I wish to offer a suggestion that I believe will make clear many things in the history of this fever hitherto unexplained on any other hypothesis. If the idea I am about to present has ever been advanced, I am unaware of it, and while there may be little in it, I desire an expression from men better able to study the matter from every standpoint, than myself.

The teachings that practically all cases of continued fever not yielding at once to quinine are typhoid, and that there is a third fever (aside from thermic fever) entirely independent of malarial origin, are equally fallacious. I believe the effort to fathom the problem along the lines of the above theories has caused us to overlook the simple truth, viz.: that the fever that is not typhoid, and that does not yield to quinine, is a *post malarial fever*, if I may suggest a name, due to lesions of the mucous membranes or the nervous system, produced by the malarial plasmodium, or, more likely, to an irritant effect of plasmodial toxins on the central nervous system, or yet, possibly to both in varying degrees

in different cases, corresponding to the characteristic regular irregularity of the disease in question. This idea seems to me to more fully meet and explain the clinical manifestations of this class of cases than any yet advanced, and I believe it will satisfy the minds of many physicians with long experience in malarial localities. Furthermore, I believe it will be borne out by the microscopic and chemical tests of malaria and typhoid fever, in at least a negative sense; for after the immense amount of laboratory work done on the subject, it would be indeed strange if a new fever would have eluded discovery; and the confusion caused by those who believe that in all cases not yielding to quinine, and in which the blood does not contain Laveran's plasmodium are typhoid fever on the one hand, and those who believe that the same cases belong to a new genus, is dissipated when we remember that had it been typhoid the clinical picture would more nearly conform to the classic type, and be confirmed by Vidal's test or the discovery of Eberth's bacillus, and that were it a new fever, the classic remittent picture of malaria would not exist in the early stages, confirmed by the presence of the hematozoon. That we must look for an entirely new fever, altogether independent of either of the others, seems to be the idea of those rejecting the typhoid, and equally so with those who do not accord with the strictly malarial nature of the case.

That every case not promptly yielding to quinine is typhoid fever will necessitate a complete unlearning of the classical clinical picture of that disease and a relearning of a new, and while having no sympathy with those who minimize the laboratory diagnosis of disease, I believe its bedside study to be at least corroborative of the truer findings of the skilled bacteriologist and chemist. On the other hand, I cannot agree with Osler and others, who believe that quinine will cure in from ten days to two weeks all southern fevers not coming under the head of typhoid or thermic fever; or not to misrepresent their views, that all cases of malarial remittent fever so-called, or rather cases known in the beginning of attack as estivo-autumnal fever, are amenable to quinine. The evidence to the contrary is overwhelming; it is the almost universal experience of practitioners in malarial districts to constantly meet these long fevers, that have no resemblance to typhoid fever in either the clinical aspect or mortality rate; neither can they be traced from case to case, nor from house to house, through the milk or water supply, as is so strikingly true of typhoid fever. And it is not the neglected cases alone I refer to, but a type frequently seen, unavoidable in many cases, a natural sequence, though not an active or real form of malaria.

I say, and I challenge proof to the contrary, that no man, however conversant with the subject, seeing a case of continued malarial fever so-called, during the late summer and fall months, can tell within a range of from one to seven weeks its duration. Given a case of malarial infection in which a post malarial toxemia (I do not refer to malarial cachexia) does not develop, we can promise a speedy cure on the simple administration of the specific.

To summarize, I believe that the so-called unknown or X fever of the south is simply a sequence

of estivo-autumnal fever, which occurs in some susceptible individuals, or in those whose systemic condition is just such as will permit the toxic effects of the malarial germ to continue the fever, *after the germs themselves have left the body*, so that it is not after the first week, or at most two weeks, strictly speaking, a malarial fever at all; neither is it a new fever, entirely independent of malaria, but a post malarial fever, much as many cases of methemoglobinuria or post paludal conditions.

This view readily accounts for the great irregularity and mild type of these cases, varying, of course, with the degree of resistance of each individual, and the amount of original toxic material absorbed; for the absence of malarial hematozoa in the blood late in the cases—and hence with the failure of quinin to cure. It also accords with the fact that these cases come in at the height of the malarial season, after the system has been for some time under malarial influences.

Furthermore, as intimated above, not only the blood test, but the remittent character of the cases in the beginning, mark them surely paludal; but when we would expect our patients' convalescence, we are confronted with a continuing fever, with no hitherto well-defined cause, lasting as long as two or three weeks, and in many cases much longer, and which is readily understood when the toxic nature of the cases is remembered, behaving much as any septic fever does. I treated a lady during the summer and fall of 1897, whose temperature reached 104 F. each day for four weeks, and 102 and 103 for four more weeks; not only did quinine fail to have the slightest effect on the fever, but nothing else seemed to influence its course. There was not at any time delirium, headache, epistaxis, rose spots, regular temperature curve, nor any of the usual typhoid fever symptoms. And yet at the beginning of this case I felt that I was dealing with a remittent malarial fever pure and simple. The patient ate a little most of the time after the first week. While this was a case of unusual severity, it is a common type met with throughout the Southern States.

I desire to call the attention of laboratory men to this line of thought, and also to suggest that if investigation should confirm it, the possible good effect of a serum treatment, or antitoxin, made from the blood of animals immunized to malaria by inoculation, should any such be found susceptible to its virus. In this case the routine treatment would be quinine in the beginning, or until the malarial bodies disappeared from the blood, to be followed by the antitoxin during the remainder of the attack.

Hoping to be to some extent instrumental in clearing up the question of this vexing fever, I appeal to the experience of every man in malarial localities, and to the negative results of quinine treatment and laboratory research, to substantiate this theory.

3. Ruptures and Traumatisms of the Thoracic Duct.
B. K. FINKELSTEIN.

4. A Contribution to the Study of the Toxic Manifestations of the Plague in Man. A. F. VIGOURA.

1.—Arapoff reports the case of a peasant, 33 years old, who has had three attacks of pleuritis at intervals of several years. The last attack resulted in a pyothorax for which the patient was operated. On opening the chest cavity, a considerable amount of thick, green, odorless pus was evacuated. On the walls of the pleura the examining finger encountered bony formations in the shape of small plates firmly adherent to the pleura. When removed and examined, these showed the consistency and color of bone, possessing a smooth outer surface, while that next to the pleura was rough. Microscopically, however, no resemblance between these and true bone could be discovered. Cellular elements were absent, except a barely perceptible network of fibres of connective tissue infiltrated with lime salts. From the pus a pure culture of *micrococcus cercus albus* was isolated, which, according to the author's view, was responsible for the deposit of lime salts into the chronic exudate. The patient's recovery was slow and frequently interrupted by elevation of temperature which seemed to have coincided with the discharge of the calcareous bodies. The author believes that the case would be more properly designated as one of pleuritis petrificans. [A. R.]

2.—Vorobieff treated 30 cases of typical acute articular rheumatism exclusively with aspirin in doses of 0.5 to 1 gram three times daily. Within 15 to 30 minutes after the ingestion of the drug the patients developed a profuse perspiration, necessitating frequent changes of the linen. At the same time the pain subsided and the general condition of the patient improved markedly. The temperature also fell to the extent of 1 degree, rising in 4 to 5 hours. In favorable cases recovery took place in 3 to 4 days after instituting the treatment which was usually commenced on the third day of the disease. On the heart no injurious effects were noticed; the frequency of the pulse as well as the blood pressure remained unchanged. Only in one case was the pulse reduced to 50 beats a minute. The digestive disturbances usually accompanying the onset of the disease subsided with the general improvement. With regards to cardiac complications it was observed that aspirin does not prevent them. Of 15 cases in which the attack was primary 5 developed valvular lesions; of the other 15 which have had previous attacks, 7 already suffered from cardiac lesions, while in 2 the latter developed during the last attack. The action of aspirin is quite transitory, and it should be given without any considerable interruption for as long as 2 weeks after the patient has apparently recovered, otherwise a relapse is imminent. The author concludes by stating that while aspirin possesses certain advantages over salicylate of soda by being more rapid in its action, tasteless and harmless, it is nevertheless inferior to the latter as a radical cure. [A. R.]

3.—Will be abstracted when concluded.

4.—Vigoura describes some of his experiments on monkeys performed in 1898 which prove that the skin manifestations of the plague are due to the toxins. By injecting large doses of Lustig's and Galtcott's nucleo-proteid obtained from cultures of the plague bacillus, the author produced gangrenes of the skin at the point of inoculation. This was accompanied by a marked elevation of temperature and other grave symptoms which threatened the life of the animals. The fact that fatal cases of the plague have been known to be free from fever is explained by the author by the observation that when large doses of the toxins of the plague bacillus are injected intravenously or intraperitoneally the temperature is lowered. [A. R.]

The Consideration of Ancestry in the Diagnosis of Hysterical Coxalgia.—M. Lerouge (*Journal des Sciences Médicales de Lille*, May, 25, 1901) reports the case of a boy of 13, who complained for some weeks of pain in the right hip, following a knock. These pains had become violent at night. Examination showed all the signs of coxalgia, except atrophy. But the pain was intense and seemed deep in the tissues. The child was also in excellent physical condition. The father was rheumatic; the mother hysterical and neuralgic. A sister is also hysterical, and the boy has already had convulsions and chorea. Under chloroform all signs of coxalgia disappeared. Three applications of the thermocautery to the painful spot cured the patient, with no recurrence since. [M. O.]

The Alcohol Question Again.—Much of the voluminous literature on this subject is either primarily polemical, or influenced by such strong prejudice, that is it not adapted to calm review. A recent contribution of a scientific character is a paper by Dr. G. Sims Woodhead, of Cambridge, England, introductory to a discussion before the Edinburgh Medico-Chirurgical Society. Unfortunately, the remainder of the discussion is available only as a very brief abstract, so that it is not possible to examine the statements of the paper in the light of the extended opinions of any of the experienced clinicians who heard it. Dr. Woodhead, being a pathologist, considers the topic largely from that point of view and gives but little information drawn from actual clinical observation. We find much allusion to animal experimentation. It seems to us that while such experimentation has its fields of great usefulness, this is a line in which it can be of but little value and may even mislead. After all, the great prompting motive for inquiries on this topic is the hope of determining positively the value of fermented beverages when used in moderation by persons of adult life and fair health. No one has ever doubted the danger of the excessive use of such beverages, nor is there much difference of opinion among informed persons as to the importance of restricting the use in childhood. It seems to us, therefore, that to give large doses of alcohol to small animals, especially to introduce it hypodermically into the peritoneal cavity, cannot afford either physiological or pathological results that bear strongly on the great problem.

Dr. Woodhead sums up his paper as follows: Alcohol is a narcotic poison, and a drug which may be valuable but is more dangerous than any other drug in the pharmacopeia. Its food value is always low and temporary and is usually zero.

Among other interesting statements made in the paper is that the use of alcohol tends to reduce the vital resistance to infection, but this view, based by Dr. Woodhead largely on the results of experiments reported by others, was challenged by Dr. T. R. Fraser, who alluded to the relative mortality of Hindoos (total abstainers) and Europeans from plague. Dr. Clouston said that the frequency of

alcoholism among the insane may be a consequence as much as a cause of the neuropathic condition.

Almost all the observations on the physiological effects of alcohol overlook the fact that, in the first place, commercial alcohol varies in purity and that the adventitious substances, though usually small in proportion, are often highly toxic. In very few of the reports of experiments is it stated that the character and amount of these impurities were ascertained; indeed, the determination of some of these substances is very difficult. In the second place, commercial alcohol or even pure alcohol does not represent, in any degree of solution, exactly the standard fermented beverages, so far as their dietetic relations are concerned. A pure alcohol, doubtless, furnishes the fundamental stimulating action for which liquors are used in therapeutics, but the effects of long continued use of liquors will include the effects of the by-products of fermentation and distillation.

Dr. Woodhead, as will be seen by the summary given above, agreed with those who do not accept Atwater's experiments as demonstrating the food value of alcohol. He quotes Madden's argument, that alcohol differs greatly from the carbohydrates and fats, in that it is a powerful protoplasmic poison, while the true foods exert no such effect. Dr. Woodhead also notes a chemical theory of Ehrlich's bearing on the same point.

No substantial agreement can be reached among the disputants on this phase of the question until they decide on some definite meaning of the term food. If this be taken to cover anything that can be changed in the body so as to yield some form of energy, then the list will be enlarged so as to take in not only alcohol but many of the best known poisons.

It is in the discussion of this question that Dr. Woodhead makes one of the peculiar slips in chemistry that are so painfully frequent in the writings of almost all grades of medical men. Speaking of the ready oxidability of alcohol, and comparing it with phosphorus, he suggests a common chemical reason for the similarity of the degenerations (fatty) produced by these agents. Both, he says, use the oxy-

gen of the blood. Let us see where this analogy will lead us. A grain of phosphorus may be regarded as a fatal dose. Presumably trustworthy reports give instances of death from much smaller amounts; in one case the death of a child from one-fiftieth of a grain. Now one grain of phosphorus requires to bring it to its highest known stage of oxidation a trifle over one and one-third grains of oxygen. Can we assume for a moment that this slight absorption of oxygen could upset the functions of the system as we see occur in phosphorous poisoning? Besides if we know anything about the pathological chemistry of phosphorus poisoning it is that it does not result from the formation of the highest oxide, for that body is not actively poisonous.

Koch's Address on Malaria.—We are indebted to Professor Koch for an address on malaria, which was delivered while he was in England last month. Professor Koch's experience with the many phases of malaria has led him to suggest a method for exterminating this widespread and ancient disease. Briefly summarized, this plan, which he proclaims as "my method," consists of:

(1) Making a microscopical examination of the blood of every individual suffering from malaria and in every suspected case, so as to establish the diagnosis.

(2) Training non-medical men to examine the blood in order to facilitate the work of the physician in malarious districts.

(3) Prompt administration of quinine, and its long-continued use—for a period of weeks or months—in every case of malaria.

(4) The establishment of quinine dispensaries to supply this drug to individuals at the lowest price and in an unadulterated condition.

(5) Exterminating the parasite in the blood of children, in which especially it propagates itself.

In making these suggestions Koch presupposes that quinine can destroy malarial parasites or render them harmless, and he holds the now accepted view that the infection is only transmitted by mosquitoes.

We concur with most of the views set forth by Koch, which, however, are by no means original with him, but which correspond in a general way to the opinions which have been advanced by most competent writers and investigators. They are a part of the common stock of knowledge. The influence which Professor Koch will wield with the public in regard to the prevention of malaria will possibly be felt, for few evidently are more ambitious to impress the public than himself. Few scientists however, will admit that the German investigator has sufficient grounds for proclaiming this method

as a measure first conceived and proposed by himself. This assumption, in fact, is the only original and remarkable thing in the address. Have not all physicians recognized the therapeutic value of cinchona almost since its introduction into Europe in 1640? Have not clinicians recognized the specific merits of quinine in malaria, and that it is the most useful drug known to combat the infectious principle of this disease? Is not this ancient history now? And finally, have not all competent observers and teachers repeatedly emphasized the fact that the most approved and practical method and the only positive means for the verification of the diagnosis of malaria, is the microscopical test? Many distinguished workers in this field, however (and Celli may be mentioned amongst these), inform us that quinine will not always destroy or render the malarial parasite harmless, and therefore prevent the spread of the disease. This applies to many of the cases of estivo-autumnal fever. Celli, in referring to the effect of quinine on the estivo-autumnal parasite, states that, "upon these forms of parasites, which are the most dangerous from the epidemic point of view, quinine has no influence." During the period of incubation, when perhaps only prodromal symptoms manifest themselves (and the disease is not often suspected at this time) there are to be found circulating in the blood, although in fewer numbers than when the disease is fully developed, malarial parasites which are capable of being a source of further infection. Relapses occur at times, even after the most careful and prolonged administration of quinine during the initial attack.

In our efforts to exterminate the malarial parasite, we should use every practical means at our command. The attack on this disease should be made from all sides. We should insist upon the early establishment of a diagnosis by means of the microscope. (See *Philadelphia Medical Journal*, March 30, 1901). The various prophylactic measures which are to be found so carefully outlined in all modern text-books, are of the greatest importance in checking the spread of this disease. We believe that individuals should be shielded from the bites of the mosquitoes, and efforts should be made to exterminate these insects. But all this is certainly not due to Koch or his "method."

Modern Gunshot Wounds.—In his address before the British Medical Association on "Some Surgical Lessons from the Campaign in South Africa," Sir William Thomson discourses in an interesting manner on the subject of gunshot injuries.

Speaking of the general effect of modern small-bore fire he shows that as a result of the recent changes in the calibre and consistence of bullets

modern warfare is much more humane than was that of a generation ago. One interesting fact to which attention is called is that the modern bullet striking the soft parts sideways, after a ricochet, often will produce such extensive laceration of the tissues, particularly at the wound of exit, that the surgeon may be inclined to believe the wound to be the result of an explosive bullet. The author's experience regarding injuries of the soft parts by the modern bullet coincides exactly with that of our own surgeons in the late war in Cuba and the Philippines. The rapidity of repair, even in long flesh wounds of the extremities, was most remarkable.

Sir William does not put much credence in the theory that the bullet is aseptic by the heat generated in its flight. The factors tending to the primary healing of these wounds he thinks are: The early application of the first dressing, the immobilization of the part by bandages, and the small track left by the bullet, which, by promptly collapsing, excludes the air. The dry climate of South Africa is also thought to have contributed largely to the quick healing of the wounds. The modern bullet was found to produce extensive bone injury when it entered the latter at short range. These bullets seldom lodged in the bone as was the case with the older form of bullet.

Attention is called to the wonderful improvement made in the treatment of gunshot wounds of the thigh, amputation now being the exception, whereas formerly it was the rule. The author protests against the examination of gunshot wounds in the field hospitals excepting under unusual circumstances. His attitude toward the treatment of gunshot wounds of the abdomen is very interesting, and to surgeons in civil life somewhat surprising. The war in South Africa has shown, as did our own war in Cuba and the Philippines, that the conservative treatment of these cases results in more recoveries than does the immediate opening of the abdomen and search for injuries of the intestine. A number of cases were seen in which undoubtedly the intestine had been perforated and yet the patient recovered. Except under peculiar circumstances demanding the opening of the abdomen, it is thought wise in military surgery to pursue the conservative plan of treatment. The writer is also opposed to the search for lodged bullets unless such give rise to trouble.

Reference is made to the practical absence of such infectious diseases as tetanus, erysipelas, pyemia, and hospital gangrene. Thomson agrees with von Nussbaum that "the fate of the wounded rests in the hands of the one who applies the first dressing." The bravery and conscientiousness of the medical officers of the British Army is shown by the num-

ber who have been killed or who have died from disease.

The Substitution and Adulteration of Drugs.—

The greed for gain is strongly developed in most modern business methods. Competition, perhaps, is responsible to some extent, as it is likely to reduce profit. This often leads dishonest individuals to substitute and adulterate the products of merchandise which they have for sale, so as to meet competition and still make a fair or even large profit. While this practice is confined to merchandise and materials which are not used as food or as medicine, the practice is simply dishonest, but when the methods of substitution and adulteration are applied to food and drugs the practice in addition becomes dangerous. We are concerned here mainly with the substitution and adulteration of drugs, and it is our intention not only to call attention to the fact that such a practice exists, being carried almost to an alarming extent, but also to suggest a remedy which will partly control and perhaps entirely stop the pernicious practice among pharmacists and manufacturers of drugs and chemicals with which we, as physicians, are mostly concerned. We remember an instance which occurred in Philadelphia in which a celebrated chemist had procured quite a large number of samples of laudanum from local druggists, and found the great majority of them to be below the pharmacopeal strength. Under such circumstances what physician can be certain of the dosage of tinctures and extracts which he orders in his prescriptions? Where proprietary remedies have been ordered in the original package, the package has in many instances been opened and cheaper and inferior substitutes been added. What physician does not know of this harmful and dangerous practice, yet what has been done by the profession to put a stop to it? Very little, if anything. If a physician sends patients to a pharmacist whom he knows to be honest (and unquestionably there are many conscientious and honest pharmacists), it is soon said that "the doctor gets a percentage on every prescription which he sends there." Even this is sometimes true, we are sorry to admit. The original package is not practical for prescription writing. But there is a remedy. Whenever a physician has his attention called to the fact that a prescription has been adulterated, that inferior drugs or substitutes have been used, the druggist should be reported to the County Medical Society or other local organizations, so that all physicians may know of it and see to it that their prescriptions do not go to such a pharmacist. This is honest ostracism, and will compel perhaps involuntary honesty.

Virchow vs. Koch.—A clash between two luminaries of the medical world cannot fail to excite interest. In vivid contrast with Koch's radical views on the non-transmissibility of human and bovine tuberculosis stands the conservative pronouncement of Virchow in his address before the Berlin Medical Society, on July 24th of this year. Virchow, who is prominently connected with the German investigation committee on the subject under discussion, believes that Lister's views should be given the preference, and that there is a strong possibility of Koch's views being refuted in the future. Virchow emphasizes, in a most forceful manner, that only those lesions should be considered as tubercular, in which anatomical tubercles can be demonstrated with certainty, bacillary invasion not being sufficient evidence. Regarding the identity of bovine and human tuberculosis, he states, it seems peculiar to him, that after he had claimed their dissimilarity as early as 1863 (*Virchow on Tumors, Vol. II, p. 739-41-45*), Koch should do so now, after Koch and his school had practically ignored Virchow's opinion on this subject for thirty-eight years.

The Etymology of Medical Terms.—A correspondent whose opinion we esteem highly, has sent us a protest against the word "Zomotherapy" which appeared in these columns recently. The etymology does not suit him. The Greek word means "broth," not "meat," and our correspondent takes occasion to inveigh not only against this word, but also against a great many other compound Hellenic words now used in medicine. As for ourselves, we are willing to agree to almost anything about etymology (or, in this instance, onomatology). Mankind have always taken great liberties in coining words, and doubtless will continue to take such liberties, and we do not blame them. Language was made for man, not man for language. Exactness and purity in the derivation of words are not always practicable. A certain poetic license is allowable. When we consider the word "melancholia" and reflect that it means literally "black bile," we may be melancholy as a consequence, but it does not follow that our bile is black. "Hysteria" means a disease of the womb, but men and boys have it, nevertheless. We need not take language too literally. The purists who wish to reform language and spelling, do not pause to reflect that these things existed long before reformers were born, and will continue to exist long after they are forgotten. As for "Zomotherapy," we did not invent the word, and so we do not feel called upon to defend it.

The Anti-Diphtheritic Serum.—Although physicians have reached a practical unanimity regarding the value of anti-diphtheritic serum if used early in the disease, that is to say, the negative voice is no stronger than it is regarding vaccination; nevertheless, carefully compiled statistics are still interesting. We wish to call particular attention to those obtained by Cuno (*Muenchener Medicinische Wochenschrift*, May, 1901), in the course of 18 years' service in Christ's Children's Hospital, at Frankfurt. The diphtheritic serum was commenced on the 1st of October, 1894. Up to that time 1928 children had been treated for diphtheria by him. Seven hundred and eight died, that is 36.7%. Of the total number 561 were operated upon for stenosis of the larynx, and 363 died; a mortality of 64.7%. Since the antitoxic serum was introduced, 1257 children have been treated by him. One hundred and eighteen died; that is, 9.4%. One hundred and sixty-four were operated upon for stenosis of the larynx, with 55 deaths, a percentage of 33.5%. The most striking features of these figures are first, the extraordinary reduction in mortality, from 36% to 9%, and secondly, the very marked reduction in the number of cases requiring operation. Statistics such as these are more impressive than any amount of animal experimentation.

The Anatomy of Melancholia.—Few medical readers who have attempted to wade through Burton's quaint and pedantic old book have probably stopped to think that the time might come when the "Anatomy of Melancholy" would be rewritten in a serious vein by a modern pathologist. But we have lived to see that day. In the August number of the *Journal of Mental Science* there appears a paper by Dr. Bernard Hollander, entitled the "Cerebral Localization of Melancholia." The author, with a show of learning that would have done credit to old Burton himself, attempts to locate the "centre" for melancholia in the parietal lobe. It is necessary to read the paper in order to fully appreciate it. Since Burton's time there surely has been no such attempt as this to write the anatomy of melancholy. Dr. Hollander has collected from the journals a vast array of cases in which there were all sorts of lesions in this particular region of the brain and in which he finds evidence of melancholia as a symptom. From this standpoint he boldly advances to his thesis, which is that melancholia is located in and about the angular and supramarginal gyri. The paper is somewhat scholastic: that is to say, it is the result of a diligent still hunt through books and medical journals. The thesis is an assumption for which the proof is gathered by a conscientious resort to the libraries.

Dr. Hollander argues that simple melancholia has for its basis a morbid emotion of fear. This emotion must take its rise in a limited region of the brain. This region is in the parietal lobe, as proved by the facts that the physical expression of fear (in the facial muscles) is reproduced in animals by excitation of the central parietal area; that this same area has a close connection with the sympathetic nervous system and the vaso-motor nerves which are both affected in melancholia; and that, finally, lesions of this area cause rise of blood pressure, alterations of sensibility, disturbances of vision and cortical blindness, all of which may accompany the melancholic state.

Such is the logic of the paper. But we maintain that fear is not the badge of melancholia. The true psychical state is the sense of personal unworthiness. However, we may point out that the idea of localization in psychiatry is not entirely new. The hallucinations of the insane have been thought to be due to circumscribed lesions in the cortex; fixed ideas or imperative conceptions have also been assigned a local habitation in the brain; and, again, a distinct inhibition of thought (an unmistakable symptom to one who has once seen it) is caused by lesions of the frontal lobes. Therefore, while Dr. Hollander's paper may not be entirely convincing, it is at least suggestive.

Lead Forward the Horned Ruminant.—In the last number of the *Medical Record*, Dr. Wallace Wood, of New York, has issued another of his remarkable and characteristic papers on cerebral localization. His paper is entitled "The Summit Fissure." We shall not attempt a criticism of Dr. Wallace Wood's paper. We confess that the task is quite beyond our capacity. The paper is phenomenal; no other word will describe it. After a panegyric on the ox for the simplicity of its cerebral topography, Dr. Wallace Wood demands that the Horned Ruminant be led forward. We merely desire to suggest that when the Horned Ruminant is led forward, the useful beast be loaded up with a translation and an exegesis of Dr. Wallace Wood's papers on cerebral localization so that an ordinary scientist may be able to understand them.

Compression of the Spinal Roots in the Paraplegia of Pott's Disease.—Touche reviews 22 cases of paraplegia in Pott's Disease, seen in the last two years. 12 of them died, the diagnosis being confirmed by autopsy. Pain was generally present in the legs, occasionally lamenating in character. It appeared in zones, descending the extremities. Areas of anesthesia appeared in the same way, each spinal root showing the effect of pressure. The motor symptoms were not so plainly radical. Touche believes that these root symptoms are hidden in many cases by medullary symptoms. Therefore the diagnosis is difficult. When the lumbar and sacral roots are affected, there is retention of urine; when only the medulla is diseased, there is incontinence. Histological examination proves this. (*Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris*, 1901, No. 2). [M. O.]

Reviews.

Mosquitoes. How they Live; How they carry Disease; How they are Classified; and how they may be Destroyed. By L. O. Howard, Ph. D., of the Department of Agriculture, Washington, D. C., New York, McClure, Phillips & Co., 1901.

The author of this book is a distinguished entomologist who has seized the opportunity when it is ripe to write a full description of the mosquito. If not much can be said in defense of this insect there is at least a great deal that can be said about it that is highly interesting. This is shown on every page of Dr. Howard's book. The central idea in the work is, of course, that the mosquito is a pest, and an agent for the dissemination of disease; but Dr. Howard shows everywhere that he is an enthusiastic naturalist, and that, as a scientist, he is not a little in love with the object of his research. This is as it should be, and it has inspired the author to write a little treatise which is an entertaining contribution to popular natural history at the same time that it fulfils its purpose admirably as a work in hygiene and preventive medicine. We know of no book in fact (and we imagine there is none in the English language) that gives so much and so useful information in short space on this subject as the one before us. We can fully appreciate its value as a supplementary volume in the wide literature of malaria.

The mosquito, in truth, is an extraordinary creature when seen under a magnifying glass. Like all animate creation it has its own adaptation to its environment; like all created forms it is wonderful in its perfection, and in the mystery of its existence. All nature is a symphony, and even the mosquito is not to be despised as a contributor to the general harmony. This truth may be difficult to realize until one approaches the subject through the end of a microscope. Dr. Howard describes the *Culicidae* (which is their scientific cognomen) from the egg, through the larva and pupa, to the perfect insect. Their habits, their life history, their anatomy, their many genera and species, their distribution, their relation to disease, their many natural enemies (and they have quite a lot) and the best way of getting rid of them—all these subjects are discussed in this small compact book in a way to interest and instruct all kinds of readers alike. The work is too full of matter for us to attempt to dissect it here, but we have read it with such pleasure and profit that we do not hesitate to recommend it to our readers. [J. H. L.]

Transactions of the American Climatological Association for the year 1900. Vol. XVI. Philadelphia. Printed for the Association, 1900.

It does seem that a year is a long time to elapse between the reading of the papers contained in this volume and their publication, and that their value and interest would suffer by the delay. The force of this criticism, it is true, is somewhat neutralized by the fact that many of the communications probably have already been published elsewhere, but this circumstance raises a question as to the wisdom of the present method of publication. The time has come, it appears to us, when papers of the quality of those in this volume receive the earliest publication possible, and their presentation in the present after so long an interval seems to be like a waste of good money. While many of the subjects here discussed have some relation to climate, all do not, as will be indicated by the statement that among the papers are two on endocarditis, one on aneurysm, and one on leukemia. Of the whole number of 21, 13 are on various phases of tuberculosis. The volume contains also a good photograph of the late Dr. Alfred Stillé. [A. A. E.]

Correspondence.

ECHOES FROM THE TUBERCULOSIS CONGRESS.

By M. P. RAVENEL, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal:

The sensation of the meeting was Koch's ill-advised and unfounded dictum on the uselessness of precautions against the transmission of bovine tuberculosis to man. It has raised universal opposition among those who work. Lord Lister followed him in a strong protest against his conclusions, and after him Nocard, Bang, and Sims Woodhead, all spoke in the same strain. The next day at the general meeting Prof. McFadyen read his paper. I think he demonstrated the fallacy of Koch's views. I have spoken to many men of almost all nations, and all condemn the method of his announcement, as well as the insufficiency of his grounds. I am told on responsible authority that even the Germans are against Koch's views. All the papers read by the German delegates showed that they held views opposed to Koch. I had a talk with Koch himself on the subject. He advises further studies, and feeling this he should not have made such a positive statement. I have visited the State Veterinary School at Brussels, and spoken with most of the leading men there. Without exception they oppose Koch's view, and Prof. Gratala said to me "He has made trouble for all the world." In the *Lancet* for August 3rd, there is a strong letter from Copeman showing a grave omission of post mortem testimony by Koch; namely that he does not tell us what intestinal lesions he found in his calves infected by feeding. Dr. Pearson and I have held for a long time that *food tuberculosis may appear first in the lungs or cervical glands*. I have just received a letter from Dr. Pearson saying that he has killed two cows fed on tuberculous matter, and "both had extensively tubercular lungs, and lesions nowhere else. The post-pharyngeal lymph glands were normal. Neither had the slightest disease along the digestive tract." We have made similar observations repeatedly on dogs and pigs. One matter was clearly brought out in the section on Pathology and Bacteriology, which Dr. Pearson and I have held also for a long time—namely that the tubercle bacillus can penetrate certain membranes or tissues like the intestine, and leave no trace of its entrance, the lesions appearing in neighboring glands, or even further away. In view of this, which was almost the unanimous opinion of those present, it seems most fallacious to deny the possibility of a given tuberculosis being of intestinal origin because the primary lesions are found elsewhere than in the intestine. In other words, it is possible for the tubercle bacillus to penetrate the intestinal wall, perhaps with fat globules; they enter the thoracic duct, and get into the blood stream, which desposits them by ejection in the lungs, leaving no trace of intestinal tuberculosis. Taking this view we may claim that tuberculosis of intestinal origin is more common than post mortem examinations indicate.

We had a most interesting general meeting devoted to the discussion of tuberculin, and its use as a diagnostic and curative agent in man. Dr. Herron advocated it strongly. Koch spoke also, and of course in support of tuberculin. The most important point brought out was, that tuberculin should be used only when the temperature is normal; and a second injection should not be given until the temperature has returned to normal. This it seems is not always obtainable, especially in those rapid cases of phthisis florida. Koch was asked to reply to a question on this point, and said that the temperature could generally be brought to normal by absolute rest. This was doubted by many present. I should say that my impression was that as a whole the meeting was in favor of the use of tuberculin as a diagnostic agent; less so as regarded its use for treatment. Some very strong men, such as Dr. Williams, of the Brompton Hospital, were opposed to the use of tuberculin

under any circumstances, regarding it as useless and dangerous. This opinion of Dr. Williams was based on extensive trials of it.

You will have seen the resolutions passed at the close of the Congress before this letter reaches you. I cannot say that they contained anything new. Sanatoria are urged and recommended, not only to cure those sick, but as means to prevent the spread of the disease. While no resolution directly condemnatory of Koch's views was passed, it was stated in one that no effort should be relaxed to prevent the spread of tuberculosis from animals to man. (Not the exact words). The prevention of spitting was urged strongly, spitting being regarded as the chief means of the spread of tuberculosis.

I was asked to appear before the Local Government Board and give a talk on tuberculosis, which I did. The English feel that tremendous damage has been done to their efforts to secure a good meat and milk supply. I have never seen such excitement over any scientific paper. Many men are bitter in their denunciation of Koch, holding that even if he proves correct, he should not have made such a statement on such slight evidence in view of the money interests at stake, to say nothing of the danger to health of multitudes. They hold that the matter is too important to be settled by the word of one man based on 19 experiments. One good will result—the experimental work which will be inaugurated in consequence. The English demand a Royal Commission unanimously, and I think one will certainly be ordered shortly. A committee of the strongest men in England will soon wait on the Premier with a strong presentation of the case, and ask for a Royal Commission.

MOSQUITOES AND YELLOW FEVER.

By W. N. BISPHAM, M. D., Lieutenant and Asst. Surgeon,
U. S. A., Havana, Cuba.

To the Editor of the Philadelphia Medical Journal:

I have just read in your issue of August 3d, the excellent article by Dr. Purnell on the Etiology of Yellow Fever, but I find that I cannot agree with him in the conclusions he deduces from the observations cited, and furthermore careful investigations carried on in and about this city for the last two years disprove them decidedly. In the first place he cites several cases of fever occurring on ships some days out from port; one as long as 68 days. In mentioning this he says "It seems to me to be utterly impossible to reconcile the mosquito theory with any of the above; while the life of the mosquito has not been determined, the shortest period mentioned above, certainly exceeds a mosquito's existence." Referring to the article by Dr. Reed in the *Journal of American Medicine* I find it stated that one infected mosquito lived until the 71st day and had bitten a non-immune with a positive result on the 57th day. Mosquitoes observed by Mr. Le Prince of the Havana Sanitary office, have lived up to 70 days. On this reservation I have also observed some mosquitoes living nearly 60 days after all breeding places have been destroyed. This last was particularly suggestive as the insects were living in the open where they could be preyed upon by their numerous enemies. In all of these cases "*Culex Fasciatus*" was the species observed.

From these observations it seems that the life of the mosquito has not been decidedly determined and it would not surprise me if in the future, insects were observed to live even longer than has been reported. In another portion of his article he gives statistics of the number of cases occurring at certain places in a definite length of time. In the epidemic of 1897, in Edwards, Miss., 726 cases in 60 days, and that of 1878, in the Mississippi Valley, 72,000 cases presumably during the whole summer. He ends the paragraph by this sentence "Is it reasonable to suppose it was accomplished by the mosquito?" This statement strikes me as being absurd, for any one who has observed

the life cycle of the mosquito, is familiar with the extreme fecundity of this insect. Howard observed that 19,110 mosquitoes were counted in one barrel, and I have noticed here that one small can of water raised enough mosquitoes to make it extremely unpleasant for any one to come within one hundred yards of it. This certainly shows that there would be no lack of insects to spread the disease, and as it has been decidedly proven that mosquitoes are carried on railroad trains, in baggage, etc. I see nothing in his statement which presents proof against this theory. Further on he mentions several cases of recrudescence observed during warm months of the summer of the year following one in which an epidemic had taken place, stating, "It can scarcely be conceived that the mosquito could harbor the germ for such a time." This is another point in which he shows lack of information on the subject, for it is distinctly stated by Howard and others that the mosquito has frequently been observed to hibernate throughout an entire winter and if a non-infected insect could hibernate why could not an infected one do so?

In the first part of his article he makes this observation "Unless the proper meteorological conditions prevail the poison seems to be inert." That is perfectly true and it has been well proven by different authorities including La Roche, and is a well known fact that mosquitoes are only active in warm and mild weather and that their activity is inhibited by cold. This is distinctly shown even in Havana where the temperature is never very low. Here the mosquito is quieted by a temperature between 50° and 60° F. On this point he brings up a comparison between a Yellow fever camp outside of Memphis, during the epidemic of 1878 and the experiment camp at Quemados in 1900. He says "If the bedding and clothing in the hospital at camp Joe Williams, during the summer weather did not become infected, is there not good reason to suppose that the material taken from Las Animas Hospital and Quemados in November and December, escaped likewise?" In the first place it has been observed from time immemorial that moving from a place which is suffering from an epidemic has enabled those taking the move to escape the fever though very often a few cases have been reported in the first camp. The reason of all this is that what few mosquitoes might be taken to the camp in the first place can find no suitable place to breed as very little water is allowed to stand in cans about the grounds on account of the usual trouble in obtaining it and therefore they are soon killed. In the second place, during the months of November and December of last year in Havana, the thermometer only once registered a temperature below 70 F. and also the fomites were kept in a building which was closed at all times and during twelve out of 24 hours the thermometer registered between 92 F. and 95 F. and never sank below 70 F. at any time.

Further on he mentions the fact that there are many mosquitoes in and about Memphis, but he does not remember that recent investigations have proven that the *Culex* almost always breeds in artificial collections of water which are more usually found about houses (Manson) and the variety of mosquito inhabiting the country districts is likely to be *Anopheles*, or some other, not *Culex*.

He also lays some stress on the Epidemic of Yellow fever in Edwards, Miss., during the year 1897, giving a partial history of several cases, with stress laid upon the point that the patients mentioned were taken sick after a short interval (not more than 11 days) after the supposed first exposure. In these accounts he does not give a complete enough elimination of all other chances of exposures to the infection. The reports are given with stress laid upon only one supposed means of infection and no other method is considered. This lack of a complete history is very noticeable, particularly in reports of cases twenty years or more ago when bacteriology was in its infancy and observations were not made as carefully as they are at present. Furthermore in "conclusion 3" of Dr. Reed he does not state as a positive fact that twelve days are requisite

before the mosquito can convey the infection but says that it appears to be so.

In one case it is stated that no other cases occurred in a house after the death of an inmate until the lapse of twenty days. The recrudescence of the fever he attributes to fomites. Why could not infected mosquitoes remain in the house for that length of time when they have been observed to live for 70 days? Other cases brought up in the same way can be dismissed with the same query.

Finally he makes the statement; "Among the many sanitary measures adopted looking to the control of yellow fever epidemics and to the complete eradication of the disease no exertions were ever directed toward the mosquito extermination." That is a great mistake for from time immemorial sulphur has been used as a disinfectant and was always freely used in epidemics of all supposed contagious diseases. On investigation it has been found that sulphur destroys the mosquito and therefore it naturally served to put an end to the epidemic. Therefore the reason why disinfection aided in stamping out the disease was because it killed the infected mosquitoes.

In conclusion I take the liberty to call Dr. Purnell's attention to the fact that very many epidemics are spread by mild cases which are unsuspected and therefore unprotected. This is a factor which ought to receive more attention and study.

Ascending and Descending Renal Tuberculosis.—Dr. Alfred Pousson presented the case of a man of 44, of excellent ancestry, with a suspicion of tuberculosis. His wife and three children are healthy and he has never been ill himself. For the past seven months he has felt a frequent desire to urinate, and noticed a few drops of blood occasionally at the end of micturition. His appetite began to fail and he grew thin. Then his right testicle swelled. About a month ago he noted radiating pain in the right lumbar region. Examination shows the right epididymis swollen and indurated, the absence of cystitis, pain over the right ureter on pressure, and a palpable, slightly tender right kidney. Rectal examination shows the right seminal vesical and right lobe of the prostate to be enlarged and hard. Examination of the urine gives decreased urea, increased chlorides, a trace of albumen, and numerous tubercle bacilli. Tuberculosis of the kidney may be caused by the bacilli reaching the kidney in the blood, with a miliary tuberculosis of the kidney following. This eventually causes descending tuberculosis of the urinary tract with pyelonephritis. Or the bacilli reach the kidney by ascending tuberculosis, from the urethra, bladder, and ureter, with pyelonephritis resulting much sooner. The symptoms of descending tuberculosis are renal pain, first, in the lumbar region; then vesical symptoms; and finally hematuria. In the case reported the diagnosis of ascending renal tuberculosis was made. Pousson advises extirpation of the kidney when tuberculosis exists.—(*Bulletin Medical*, 1901, No. 42). [M. O.]

Spinal Anesthesia.—R. Jedlick (*Sbornik klinicky*, Vol. 11: *Vratch*, Vol. XXII, No. 12) places on record, together with a large number of cases collected from literature, 101 personal observations on spinal anesthesia. He employed eucain as the less poisonous drug. 1-1.5 c.c. of a 2-3% solution were injected. Complete anesthesia was obtained in laparotomies, operations on the lower extremities, perineum, large intestines, genital organs and gynecological cases. Anesthesia appears in the legs 4 minutes after the injection; in 7-10 minutes it reached the umbilicus. Occasionally it spread on a level with the nipples and exceptionally still higher. The spread of the anesthesia depends on the diffusion of the eucain in the spinal fluid, and the author recommends that the injections be made in a recumbent posture, allowing the escape of as much spinal fluid as the amount of the anesthetic used. The heart is never affected, except in the aged, in whom this method is contraindicated. In a few cases vomiting, paralysis of the rectal sphincter and erection of the penis were observed. These effects however, are transient. The author concludes by stating that eucainization is perfectly harmless and should receive the widest application.

[A. R.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Disastrous Conflagration.—One of the most disastrous holocausts in the history of Philadelphia occurred this week. dent physicians from every hospital in the city are busily engaged reviving the prostrated and dressing the burns of the injured. The fire resulted from a bolt of lightning which struck a huge oil tank in the southern portion of the city. The indefatigable work done by the physicians on the scene of the catastrophe cannot be too highly commended.

Philadelphia Hospital Bequests.—By the will of Emily Phillips, who died on July 24th and left an estate of \$100,000, a large portion of the money was divided among charitable institutions. Following are some of the hospital bequests: Jefferson Hospital, \$10,000; Jewish Hospital, \$10,000; Pennsylvania Hospital, \$1,000. The Presbyterian Hospital received \$2,000 and the Medico-Chirurgical and Howard Hospitals \$1,000 each. Philadelphia Hospital for Incurables, \$5,000; Montefiore Home for Chronic Invalids, \$5,000; Home for Aged and Infirm Hebrews in Philadelphia, \$5,000. Aged Couples' Home, \$1,000; Children's Sanitarium Association, \$2,000.

Dysentery at Lancaster.—Dysentery recently became epidemic at the County Hospital and Insane Asylum, and has carried off five inmates since Wednesday, whilst a dozen are in a critical condition.

Vital Statistics of Philadelphia for the week ending August 17, 1901:

Total mortality	507	Cases.	Deaths.
Inflammation of the appendix 3,			
brain 11, bronchi 2, heart 1, kid-			
neys 18, nerves 1, liver 1, lungs			
28, pericardium 2, peritoneum 7,			
stomach and bowels 46, spine 1,			121
Tuberculosis of the lungs			58
Apoplexy 11, paralysis 5			16
Heart-disease of 24, dropsy of 2,			
fatty degeneration of 2, neuralgia			
of 1			29
Uremia 17, Bright's disease 8			25
Carcinoma of the face 1, breast 3,			
stomach 5, uterus 3, neck 1,			
hand 2, liver 1, pelvis 1, rectum 1,			
throat 2			
Convulsions 17, puerperal 1			18
Diphtheria	50		9
Brain, softening of			5

NEW JERSEY.

New Jersey State Hospital for the Insane.—The investigation into the food supply at the State Hospital for the Insane has been resumed, several attendants giving testimony to the alleged bad food.

NEW YORK.

Superstition Abolishes a Ward Number.—According to the *Binghamton N. Y. Dispatch*, for medical reasons the State Hospital authorities have found it necessary to abolish Ward 13. It was found that this number had a depressing effect on many patients whose superstitions were increased by their infirmities. There is now no No. 13 in

the State Hospital, the ward numbers jumping from 12 to 14 for the benefit of the patients. It is the first time that this alleged unlucky number has received official recognition by State authorities.

NEW ENGLAND.

New Hospital for Tuberculosis.—Work has been begun on a new hospital for tuberculosis on Newington Mountain, a high suburban section of Hartford, Conn. The State has appropriated \$25,000 for the enterprise, and an amount nearly as large has been contributed by private individuals.

Smallpox in Boston.—Five cases have developed in Boston since one week.

WESTERN STATES.

A Neuropathist Fined.—A "Neuropathist," of Los Angeles, Cal., was recently fined \$100 for practicing medicine without a license; on appeal, the judgment of the lower court was affirmed by the Supreme Court.

Rigid Enforcement of Medical Laws in California.—The Los Angeles, Cal. board of health has issued a notice to every practicing physician, dentist and pharmacist in the city, notifying them that in case they have not registered according to law, but ten days more will be permitted them to do so, and that a failure to comply will be followed by legal prosecution. A fine of from \$50 to \$500, or imprisonment from 30 to 365 days, or both, is the penalty fixed for attempting to practice without a license.

Death of Dr. Cooper.—Dr. Charles B. Cooper, of San Francisco, died July 21, 1901, at his residence in San Francisco. The doctor was a prominent surgeon of that city, and a man of great ability. He graduated from Cooper Medical College in 1889, after which he spent some time in Europe. He was at one time Superintendent of the Waldeck Sanatorium, and at the time of his death was having constructed a hospital building in San Francisco.

Dr. Henry S. Nelson has succeeded Dr. William J. Byrnes as city physician of Minneapolis, Minn.

Stanford University.—Dr. T. D. Wood has resigned as Professor of Hygiene and Organic Training at Stanford University, and accepted a similar position in the Teachers' College of Columbia University.

Miami Medical College.—Dr. J. C. Oliver has been chosen Dean of Miami Medical College in place of Dr. N. P. Dandridge, resigned, and Dr. Fred. Forchheimer was elected professor of practice of medicine.

Chicago Lying-in Hospital.—The Chicago Lying-in Hospital has received a donation of \$5,000 from Abram Simmer, Waverly, Ia., for the erection of a new dispensary building, contingent upon the subscription of \$10,000 additional.

Dr. Gardner's Resignation.—Dr. M. Gardner, chief surgeon of the Southern Pacific Company, has forwarded to Governor Gage his resignation as a member of the board of managers of the Mendocino State Hospital.

College of Physicians and Surgeons.—The following officers have been elected for the coming year at the College of Physicians and Surgeons, Chicago: Dr. D. A. K. Steele, actuary; Dr. William E. Quine, dean, and Dr. Frank B. Earle, secretary, vice Dr. W. A. Pusey, resigned.

No College of Opticians.—A plan for a college for opticians was rejected at the fourth annual convention of opticians, just ended in Chicago, but it was decided to hold examinations to raise the standards of excellence among those entering the occupation. The next Convention will be held in Boston.

Medical Examination Before Marriage.—A bill has been introduced in the Colorado House of Representatives to provide for a board of medical examiners whose duty it shall be to decide upon the fitness for marriage of all applicants for marriage licenses, which may not be issued unless the Medical board recommends it. The board is to sit ten days in every month. A number of diseases and certain defects in family records are declared to be bars to marriage, after the passage of the act.

Dr. Albert P. Ohlemacher, Gallipolis, was reinstated in his position as pathologist of the State Hospital for Epileptics, August 5. This was the first official act of Superintendent Coleman.

Protest of Hospital Internes.—On account of the rule which was posted of Warden Healy, of the Cook County Hospital, Chicago, on August 1, providing that all major surgical operations must be performed by one of the attending staffs, the following statements in reply were made by the internes:

"1. Whereas, it has been stated that we are but 'students,' learning our 'trade' at the expense of county patients, we emphatically deny this. Every one of us has graduated from a reputable school, has passed the state board examination, and is entitled thereby to practice medicine and surgery in this state and is selected under civil service rules, by passing successfully an examination in medicine and surgery given every year, competitive in character, and held under the most rigid and impartial rules that govern any examination whatsoever. Such qualifications are not picked up by the wayside, but gotten only by constant application, by the expenditure of a great deal of time and of money. Moreover, every interne in this hospital has had a college training before starting in the study of medicine. 2. Whereas, it has been alleged, too much and unnecessary operating has been done by internes. We point out the fact that no operation, at any time, has been had but after a complete examination by a member of the attending staff, under his direct control and supervision. There is no authentic case in the hospital in which a patient was narcotized without the presence of an attending physician or surgeon. 3. Considering the qualifications necessary to become an interne, and the fact that every senior interne has served twelve months in preparing for surgical work, it is justly evident that we should be regarded competent to participate adequately in the care of patients. Such privileges are enjoyed by internes of every other hospital in this country and abroad. 4. Whereas, it appears as if there were friction between the hospital management and the internes. We assure you that there is nothing but good will between Warden Healy and the house surgeons.

A New Hospital for Steubenville.—Congressman J. J. Gill has given \$35,000 for the establishment of a hospital in the city of Steubenville, Ohio.

SOUTHERN STATES.

Ambulance has no Speed Limit.—A public hearing on the speed of the Emergency Hospital ambulance was recently held by the District Commissioners of Baltimore. It was decided that the recent order limiting the speed of that vehicle be rescinded.

Memorial to Dr. Rhett.—At Charleston, S. C., the proposition to erect an enduring memorial to the memory of the late Dr. Robert Barnwell Rhett, Jr., took practical shape on August 13 in the formation of the Robert Barnwell Rhett, Jr., M. D., Memorial Association. A number of leading citizens of Charleston met and discussed the subject at some length. The result was that a committee was appointed to draft a plan for a permanent organization such as desired, with instructions to report at its earliest convenience.

The Texas State Board of Medical Examiners, appointed by the Governor under the new Medical Practice Law, which went into effect July 8th (ult.), met in Austin, July 23rd, and organized. Dr. J. T. Wilson, of Sherman, was elected President; Dr. S. R. Burroughs, of Buffalo, Vice-President; and Dr. M. M. Smith, of Austin, Secretary and Treasurer. They formulated plans for future action and will hold their first meeting for examining applicants, at Austin, the first Tuesday in October.

Dr. Waters Returns to Johns Hopkins University.—Dr. Campbell Easter Waters, who was professor of chemistry and physics last year in the Connecticut Agricultural College, has returned to a teaching position in the University's chemical department.

Chemically Colored Sausage.—Health Commissioner Bosley, of Baltimore, is determined to pursue his crusade against chemically treated sausages. City Chemist Lehman, of Baltimore, who has examined hundreds of specimens of the chemically treated sausages stated that one aniline dye is employed to give the meat a fresh looking appearance and another aniline dye for the purpose of producing the smoked appearance of the sausage skin.

CANADA.

John Grant, M. R. C. S. Eng.—Dr. J. Grant, of Napanee, died suddenly at his home in the latter part of June. He had been practicing about forty years.

MISCELLANY.

Reward for Rats in Manila.—The Manila Board of Health offers one and one half cent for every rat killed. This action has been taken in the hope that it may assist in stamping out the plague in Manila.

A Martyr to Scientific Experiments.—It has been announced by Chief Surgeon Harvard that the experiments which have been conducted in the investigation of the propagation of yellow fever will be discontinued as far as the mosquito test is concerned. This was decided upon because one of the non-immunes who was recently bitten by an infected mosquito died of yellow fever. The man was a Spaniard, desired to become an immune, and therefore allowed himself to be bitten by an infected mosquito. Another man who was bitten is also suffering from a very bad case. Both were bitten by insects which had been set apart for the experiments of Dr. Calsdas, the Brazilian expert, who has been arranging to demonstrate the alleged efficiency of a serum as a preventive against yellow fever.

The Pathology of Sunstroke.—The editor of the *Medical Record* states that when death is sudden the condition appears to be either that of syncope from simple failure of heart action, or from direct shock to the cerebral and respiratory centers. The latter, or asphyxial form is most common and most rapidly fatal. In the more gradual hyperpyrexial variety the cerebral lesions are usually quite pronounced, including evidence of meningitis, serous effusions into the ventricles, occasionally hemorrhages into the brain substance and engorgement of the venous system with dark, fluid-blood. In general the attack is simply over-stimulation of the respiratory and circulatory centers by heat, followed by eventual exhaustion.

The Ambulatory Type of Plague.—The Board of Health of Manila in a circular letter called the attention of physicians to the necessity of extreme caution in the differentiation of the ambulatory type of plague.

Obituary.—Dr. Martin B. Cleveland, at Jacksonville, Fla., August 8, aged 66 years—Dr. Aaron E. Schaub, at Lancaster, Pa., August 8—Dr. Thomas Sappington, at Baltimore, Md., August 11, aged 85 years—Dr. Wiley Fussell, at Irwin county, Ga., August 14—Dr. James A. Williams, at New York City, August 15, aged 62 years—Dr. James Howard, Jr., at Fairmount, W. Va., August 18, aged 23 years—Dr. William W. S. Butler, at Harrisburg, Va., August 18—Dr. Frank Ravenscroft, at Friendsville, Garrett county, Md., August 11—Dr. G. Smith, at Spottsylvania county, Va., August 11, aged 71 years.

An Electrical Novelty.—Edson Brace, formerly connected with the Patent Office at Washington, has suggested to the Committee on Electricity and Electrical Appliances of the World's Fair to be held at St. Louis in 1903, that the building in which the electrical exhibits are to be displayed should be of glass and steel frame, as a means for more definitely ascertaining the physiological and therapeutic action of the electricity. In addition to this it is expected that it will also afford amusement.

Sanatoria for Tuberculosis.—E. W. Brabrook, C. B., Chief Registrar of Friendly Societies of Great Britain and Delegate of the Royal Statistical Society states that if the liability of friendly societies to claims for sickness and death would be diminished by the establishment of sanatoria, it would be to the interest of such societies to contribute to a certain extent toward their construction and maintenance. This the societies have the legal power to do, under certain conditions, by ss. 22 and 37 of the Friendly Societies Act, 1896. The extent of their interest is not so great as might be supposed. The liability of their members to phthisis is not so great as that of the general population. Again, early mortality relieves the society from its liability to future sick pay. Where children are admitted members, they are required to pass a second medical examination at the age of 16 or 18. The ages of 3,699,804 members of friendly societies are recorded: 7 per cent. being under 16; 7 per cent. between 16 and 20; 67½ per cent. between 20 and 50; 14½ per cent. between 50 and 65, and 4 per cent. over 65.

Trade unions may also, under certain conditions, join in the establishment or maintenance of a medical society. In four of these bodies, the deaths from phthisis were from 10 to 13 per cent. of the total number of deaths; and the average age at death from phthisis varied from 35½ to 39½, and from all causes from 43 to 52.

The conclusion arrived at is, that while theoretically the question put must be answered in the affirmative, the financial interest of the societies is too small to allow of its being reduced into practice to any material extent.

A New Simple Apparatus for Modifying Cow's Milk.—A new apparatus for modifying cow's milk has been constructed under the direction of Dr. C. Herman, who bases his calculations upon some of the data recently published by Dr. Holt. If milk were allowed to stand, the upper one-third gave 10 per cent. fat and the fats were in proportion to the proteids as 3 to 1. The upper half contained 7 per cent. fat and the proportion to proteids was as 2 to 1. The apparatus presented consists of a glass cylinder having an opening both above and below and being graduated into 1,000 cc. The milk is removed from below through a stopcock leaving the upper layer undisturbed. The cylinder is also graduated so as to show the fat and proteid percentages. In using the apparatus the milk is introduced up to the 1,000 cc. mark and the cream is allowed to separate. If it is desired to use milk containing fat and proteids in the proportion of 3 to 1, it is only necessary to allow the milk to flow off until it reaches the mark 3 to 1. If 3 per cent. fat is desired one has only to take 300 cc. Analysis showed that the proteid bore to the sugar a nearly fixed ratio, i. e. 1 to 1.3. per cent. A small graduated glass accompanies the cylinder and is used for determining the quantity of milk required. The apparatus was not only simple but allowed of an indefinite number of modifications. It could also be used to determine the quality of the milk, for after the cream had separated one could read off directly the percentage of cream. The specific gravity of the lower milk could be taken and from tables the composition of the milk readily calculated.

Changes in the Medical Corps of the Navy. For week ending August 17, 1901.

MEDICAL INSPECTOR F. ROGERS, detached from the Brooklyn, and ordered home—August 16.
SURGEON J. E. GARDNER, detached from the Naval Hospital, Cavite, P. I., and ordered to the Brooklyn, temporarily—August 16.
P. A. SURGEON M. S. ELLIOTT, detached from the Annapolis and ordered to the Kentucky—August 16.
P. A. Surgeon E. M. Shipp, ordered to the Cavite Naval Station—August 16.
ASST. SURGEON W. H. ULSH, detached from the Glacier and ordered to the Antipolis—August 16.
ASST. SURGEON W. E. C. HIGG, detached from the Kentucky and ordered to the Glacier—August 16.
ASST. SURGEON J. T. KENNEDY, detached from the Marine Brigade, and ordered to the Brooklyn—August 16.
ASST. SURGEON H. E. ODELL, detached from the Naval Hospital, Cavite, P. I., and to duty with the Marine Brigade—August 16.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended August 15, 1901.

H. D. GEDDINGS, passed assistant surgeon, granted leave of absence for 1 month and 15 days from August 15—August 13, 1901.
C. H. GARDNER, passed assistant surgeon, granted leave of absence for 14 days from August 17—August 9, 1901.
S. B. GRUBBS, assistant surgeon, granted leave of absence for 3 days from August 12—August 9, 1901.
J. F. ANDERSON, assistant surgeon, relieved from duty at Liverpool, England and directed to proceed to New York, N. Y., and await orders—August 13, 1901.
C. H. D. LOHR, assistant surgeon, granted leave of absence for 7 days under paragraph 17 of the Regulations—July 7, 1901.
B. W. GOLDSBOROUGH, acting assistant surgeon, granted leave of absence for 7 days from August 11—August 13, 1901. Granted leave of absence for 21 days from September 5—August 13, 1901.
H. S. PRIMROSE, acting assistant surgeon—granted leave of absence, on account of sickness, for 21 days from August 10—August 10, 1901.
S. D. ROBINS, acting assistant surgeon, granted leave of absence for 30 days from August 5—August 10, 1901.
F. R. DANRATH, hospital steward, granted leave of absence for 10 days from August 12—August 13, 1901.
M. VALERIUS, hospital steward, granted leave of absence, on account of sickness, for 23 days from August 8—August 11, 1901.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ended August 17, 1901.

Medical Men Honored.—King Edward VII recently conferred the following honors upon prominent English medical men: Knight Commander of the Royal Victorian Order on Sir Thomas Smith, Bart., F. R. C. S., Deputy Surgeon-General Henry Julius Blanc, and Mr. William Henry Bennett, F. R. C. S.; Commander of the Royal Victorian Order on Dr. Donald W. C. Hood, Mr. John Hammond Morgan, F. R. C. S., and Mr. Charles Arthur Morris, F. R. C. S.

Liverpool School of Tropical Medicine.—Dr. R. Fielding-Ould, Dr. C. Balfour Stewart, and Dr. A. S. F. Grunbaum have been appointed assistant lecturers in the Liverpool

Glasgow Royal Infirmary.—Dr. T. K. Monro, one of the physicians to the infirmary has been elected Professor Medicine at St. Mungo's College.

Appointments.—The King has appointed Dr. William Hoffmeister and Dr. Edgar Hoffmeister medical attendants to the Royal establishment at Osborne.

A Worthy Retirement.—It is reported that Surgeon-Major-Gen. W. A. Thomson, M. B., who is Honorary Physician to King Edward, has been selected for a good-service pension of one hundred pounds a year. It is nearly fifty years since he received his first commission as an army surgeon. He has served in many parts of the world, and at the time of his retirement in 1892 he was principal medical Officer in India. He was appointed Honorary Physician to Queen Victoria in 1895.

CONTINENTAL EUROPE.

Dr. Combemale, Professor of Medicine at the University of Lille, has been appointed Dean of the Medical Faculty for three years.

Dr. Recourd, Professor of Chemistry at Lyons, has been appointed Professor of Chemistry at the University of Grenoble.

Dr. Caunery has been appointed Professor of Zoology at the University of Marseilles.

Enteric Fever Among Soldiers.—In one battalion of soldiers stationed at Metz, Germany, 291 cases of enteric fever recently occurred.

Medical Extension Classes.—For the past two or three years a number of German universities have established what are known as "medical extension classes," which serve the same purpose as the postgraduate schools of this country.

Palace to Become a Children's Hospital.—King Victor Emmanuel has decided that the Palace of Monza, near Milan, where King Humbert was staying at the time of his assassination last year, should be converted into a children's hospital and asylum, which is to bear the name of the unfortunate sovereign. Being spacious and surrounded by magnificent gardens and a park of vast extent, it is pre-eminently suited for the purpose to which it is now about to be put.

A New Library for the University of Berne.—Dr. von Zehender, formerly Professor of Ophthalmology in Rostock, has presented his library to the University of Berne.

The Air Cure for Tuberculosis at Havre.—Since February 1st, 1900, a special department, consisting of 22 beds, has been instituted by the Pasteur Hospital, Havre, for the cure of tuberculous patients by air, rest, and diet. This department, which has been established in an exceptionally favorable situation, 70 metres above the level of the sea, has received, during the first sixteen months of its working, 112 patients. The results attained were as follows: Much improved, 19 or 17 per cent.; Improved, 39 or 35 per cent.; Stationary, 30 or 27 per cent.; Become worse, 10 or 9 per cent.; Died, 14 or 13 per cent. Twenty-five patients had no bacilli in their sputa on admission; sixteen have improved. All the others were cases of advanced disease, with bad general condition, loss of appetite, and abundant expectoration. Seventy-two patients have gained in weight a little more than six pounds on an average, twenty-eight have lost weight, while twelve have remained stationary. It should be pointed out that the average duration of the stay in the hospital has been: Ninety days for those much improved; 54 days for those improved; 28 days for those stationary. These results might be better; the method can yield better results. The causes of the inadequacy were, that: 1. The patients come for treatment too late. 2. They will not continue long enough. A prominent member of the hospital stated that we must secure the co-operation of those concerned by organizing outdoor relief for their families, by propagating our views as much as possible by means of conferences, leaflets, etc., calculated to enlighten public opinion on this point; above all, by perseverance, for much can be done through time, and also by the help of new patients, who will prove our best propagandists. It is obvious that the best means of arresting the progress of tuberculosis is to employ all the resources of hygiene and of prophylaxis. But until we have succeeded in rendering the towns healthy, in overcoming intemperance, in educating public opinion, and in a good deal more besides, there will always remain poor tuberculous patients who should be isolated and cared for, to prevent them from becoming a source of danger. But up to the present the sanatorium gives the best results. All our efforts should tend in the direction of getting the system accepted and adopted by the public.

A New Protection Against Seasickness.—Dr. Galliano recently reported to the Medical Academy of Touran that a binder encircling the epigastrium was of decided value. He states that the preventive action is brought about by relieving the irritation upon the sympathetic and ganglia. He claims to have obtained excellent results.

Dr. Hermann von Widerhofer.—The sad news of the death of Dr. Widerhofer, Professor of Pediatrics at the University of Vienna, has just reached us. Almost a year

ago he was stricken with apoplexy, followed last winter by a second stroke. He never spoke again. His condition improved slightly this spring, and he was moved to Ischl in June. He grew gradually weaker there, and died on the morning of July 29th, 1901. Hermann von Widerhofer was born in Meyer on the Enns in Upper Austria on March 24th, 1832. He was graduated from the University of Vienna as a physician in 1856, and became at once both clinical assistant to Dr. Mayr, at that time Professor of Pediatrics, and physician to the Vienna Foundling Asylum. Appointed assistant to the Children's Hospital, he took charge of the pediatric clinic there after Mayr's death. He was then elected Director of the Children's Hospital, a position which he held until last year. In 1862 he became a "privat-docent" in Pediatrics; in 1865, extraordinary Professor; and in 1881, Professor of Pediatrics at the University of Vienna. His works include a number of smaller articles in the *Jahrbuch für Kinderheilkunde*, of which he was one of the editors, and several monographs published in book form. He wrote less than he taught; for his teaching was eminently practical. In 1863 Widerhofer was appointed Physician to the Imperial Family of Austria. During the 38 years of his service in that capacity, his extraordinary tact gained him the confidence not only of the Emperor, but also of the late Empress; and it is a fact that his advice, in questions concerning the Imperial Family, not only was listened to, but was always followed. The Imperial Princesses have always clung to the physician of their childhood, and have constantly shown their regard for him. The collection of tokens of the affection and esteem of Archduchesses Gisela and Marie Valerie and of their children are to be found in Widerhofer's study. Every summer he has been the guest of the Emperor at Ischl. The titles of Freiherr, Court Councillor and Baron were conferred upon him by the Emperor, the last upon the marriage of Archduchess Marie Valerie. She herself announced the fact to him, and was the first to congratulate him. At the funeral, held in Ischl July 30th, not only the Emperor, but his daughters, their husbands, and their children were present. The funeral in Vienna was held the 31st, when addresses were made by Professor Neumann, for the Medical Faculty; Professor Nothnagel, for the College of Professors; Professor Chrobak, in the name of the Association of Vienna Physicians; Professor Monti, representing Widerhofer's students; and Dr. Foltanek, representing the Children's Hospital. Baroness von Widerhofer and two sons survive him.

Budin gave an interesting report at the recent Tenth International Congress of Hygiene (*Annals of Gynecology and Pediatrics*, May, 1901), on the **Care of Young Infants**. Statistics were given from all cities in France of over 30,000 inhabitants, showing the mortality of infants under one year as compared with the total mortality during the years 1892 to 1897. The infant mortality during this time was 16.2% of the total. Budin pointed out that 53% of the children under one year died of diseases of the digestive tract and of the respiratory organs; 38.5% died of diarrhea. Budin urges that special attention should be given to the prevention of diarrheal affections in children. In Paris in 1892 was established at their lying-in hospitals what they call "first consultation for mothers." Each week mothers who are nursing their children bring them to the hospital where they were born. The child is examined and weighed and the mother is instructed in the care of the child, and when necessary furnished with sterilized milk to supplement nursing. Budin urges the duty of the municipality to furnish, especially for the poor, pure milk at low prices. He points out that the great mortality among nursing children is among those fed by the bottle, and urges this as the reason for municipal aid and inspection. [W. A. N. D.]

Syphilitic Disease of the Heart and its Curability.—S. I. Schwartz (*Medicinskoje Obozrenie*, June, 1901) reports a case of syphilitic mitral stenosis in a man who contracted syphilis 15 years back. The diagnosis was established from clinical symptoms. Antisyphilitic treatment restored the organ to an almost normal state. [A. R.]

2.—Treated editorially.

3.—McFadyean delivered an address before the British Congress on "Tubercle bacilli in cows' milk as a possible source of tuberculous disease in man." He briefly summarizes arguments upon which Prof. Koch based his recent claims: (1) Bovine tubercle bacilli are much more virulent for cattle and other domestic quadrupeds than human tubercle bacilli. (2) This difference is so marked as to constitute a means of differentiation between bovine and human tuberculosis. (3) Post-mortem observation lends proof that primary intestinal tuberculosis is extremely rare, therefore the human subject is immuned or very slightly susceptible to bovine tubercle bacilli. McFadyean states that we must admit that bovine tubercle bacilli are more virulent to cattle and also to the rabbit, dog, sheep, hog, so therefore it appears probable that man is also susceptible. He contends that the virulence of the average bovine tubercle bacillus might be reduced by passage through the human subject. In regard to the third proposition of Prof. Koch's, that primary intestinal tuberculosis from tuberculous milk and meat is extremely rare, the author gives ample post-mortem statistical evidence to show that this statement is not well founded. He is inclined to believe that animal tuberculosis is a source of human tuberculosis. [F. J. K.]

4.—Murphy makes a plea for the adoption of administrative measures necessary to prevent the sale of tuberculous meat to the public and makes the following suggestion: Meat of all animals intended for human food should be inspected before being sold. In urban, and as far as possible in rural districts, animals should be slaughtered in public slaughter-houses in order to secure efficient inspection. [F. J. K.]

5.—Lloyd reviews the veterinary work which was done under the milk clauses in Manchester and the difficulties encountered. Between January 11, 1901 and April 30, 1901, milk has been distributed from 401 farms and each farm averaged twenty-one cows. Forty-seven or 11.72 per cent. of the farms supplied samples of tuberculous milk. After careful investigation 63% of all the cows examined were found to be suffering from tuberculous udders. (F. J. K.)

6.—Kelynack communicated an article to the British Congress on Tuberculosis, on the relation of alcoholism to tuberculosis. This author contends that clinical, post-mortem, and experimental evidence supports the view that the use of alcohol predisposes to tuberculosis. [F. J. K.]

7.—McEachran suggests the following legislation for controlling and eradicating tuberculosis in animals: (1) In the list of contagious diseases tuberculosis should be placed and necessarily tuberculous animals should be dealt with under the provision of the Animal Contagious Disease Act. Local authorities should be given power to regulate the sale of the parts of carcasses which may convey infection. (2) Animals imported for breeding or dairy purposes should be subjected to the tuberculin test and if found diseased they should be prohibited from entering. (3) Only qualified veterinarians should apply the tuberculin test. (4) Animals showing clinical evidence of tuberculosis should be killed at once and animals which react to the tuberculin test should also be slaughtered. (5) Testing of an entire herd should be at the expense of the state except when dealing with imported animals. One and a half degrees should constitute a suspicious indication of tuberculosis. All animals acting in this manner are to be quarantined and re-tested unless clinical evidence of tuberculosis manifests itself, when they should be killed. A re-action of two degrees should constitute a proof of tuberculosis. (6) All disinfection should be under the supervision of Government Officials. [F. J. K.]

8.—Pentland discusses tuberculosis amongst Australian stock. This author mentions various statistics and includes several tables in his article which show the prevalence and mortality of this disease in Australia. He states that from 1894 to 1900 three thousand, one hundred and sixty head of cattle were killed for tuberculosis. He emphasizes that the most efficient plan for exterminating tuberculosis amongst cattle will be found in slaughtering all tuberculous animals. [F. J. K.]

9.—Edington writes on "the mortality amongst rats at the Cape Town docks which preceded the present epidemic of plague." As in a previous communication in the *Lancet* (June 1, 1901) he still believes that this fatality amongst the rats in these docks was not due to the plague bacillus, but to a variety of the bacillus of hemorrhagic septicemia. [F. J. K.]

MEDICAL RECORD.

August 17, 1901.

1. Syphilis of the Liver. MAX EINHORN.
2. Pregnancy Following Myomectomy. JAMES N. WEST.
3. The Summit Fissure. WALLACE WOOD.
4. Notes on Malarial Fevers in Central America. J. HOBART EGBERT.

1.—Max Einhorn discusses syphilis of the liver with notes on ten cases. He mentions that in the majority of cases of syphilis of the liver, pains in the hypochondrium are present, sometimes constantly and sometimes in the form of attacks, resembling in the latter case gall-stone colic. There were in his series various attacks of disturbances of digestion, and frequently there is general malaise, restless sleep, weakness, loss of weight, but never to such an extent as in malignant neoplasms of this organ. Icterus may be acute, persisting for a short time and then disappearing, or it may become chronic. The organ is usually found more or less swollen, extending in the right mamillary line beyond the free border of the ribs. The

organ presents a harder and smoother appearance than normally. Ascites may develop in a late stage of the disease. In none of the cases described has this stage been reached. Beside the specific treatment attention must be paid to the following points: when icterus is present, glycerine should be given, one teaspoonful doses half an hour before meals, and in the presence of an anemic condition, iron, or arsenic with iron is indicated. Marked ascites may have to be relieved by puncture. All alcoholic beverages must be forbidden, also strong tea and coffee. [T. L. C.]

2.—West is an ardent advocate of true conservatism in gynecology. He has made a study of pregnancy following myomectomy with the hope that the facts he now presents will aid in the founding of the proper course to pursue in dealing with a large portion of the cases of uterine fibro-myomata. The evolution of uterine myomectomy has been gradual since 1825, and is now one of the well recognized surgical procedures. The loss of the ovaries and uterus when occurring to a young married woman who has never borne children West regards as a tragedy in her life. The value of the ovaries on account of the secretion peculiar to them is now well recognized. The preservation of the uterus and its adnexa not only maintains the integrity of the pelvic structure and normal functions, but also offers a fair prospect of child-bearing. A comparatively large number of cases of pregnancy subsequent to myomectomy has been recorded. West gives a summary of some of these and relates a case that has occurred in his own practice. In his case 9 incisions had been made in the uterine tissue, and yet the labor lasted 12 hours and the expulsive force was ample. In 2 cases gestation was complicated by a flow of blood or amniotic fluid from utero-abdominal fistulae, which remained at the site of operation, but healthy children were born notwithstanding this complication. [W. A. N. D.]

3.—Noted editorially.

4.—J. H. Egbert presents notes on malarial fevers in Central America. The mountains of Honduras, four thousand feet above the sea level are above the mosquito belt and above the fever belt, and yet malarial fevers, both of the quotidian and tertian types, are of common occurrence. Egbert believes that they are propagated at least in part, by fleas. Malarial fevers in Tropical America are of special interest to the clinician. The spleen is frequently enlarged, especially in children. Under treatment the cases do well. He has found that a satisfactory plan of treatment is the combined administration of quinine and acetanilid, together with calomel or saline laxatives, during the run of the fever, and quinine and mineral acids, or Fowlers' solution, together with podophyllin or similar hepatic stimulants, for the subsequent disturbances. [T. L. C.]

MEDICAL NEWS.

August 17, 1901. (Vol. LXXIX, No. 7.)

1. Fibroma of the Mesentery. J. B. MURPHY.
2. Arsenic and Its Compounds; With Special Reference to Soda Cacodylate. CHARLES WILLIAM HEITZMAN.
3. Acute Peritonitis: Its Treatment upon an Etiological Basis. C. D. HILL.
4. A Plea for the Better Appreciation of the Limitations of Operative Work. A. M. CARTLEDGE.
5. The Etiology of Melancholia. H. H. STONER.

1.—In Fibroma of the Mesentery, J. B. Murphy divides the treatment as follows: (a) Aspiration. No deaths have been reported, although out of seventeen cases, nine recurred, and out of sixty-two cases, forty-seven recurred. It was found that the chylous cysts were more apt to recur; (b) Puncture with fixation of cyst wall in abdomen, incision and drainage. Pean's mortality in nineteen cases was five per cent.; (c) Primary enucleation of cyst. Very dangerous with a mortality of sixty percent., principally due to shock, peritonitis and intestinal gangrene; (d) Primary drainage with secondary enucleation. This procedure is one with very little danger when the tumors are greatly

reduced in size by drainage. The author also gives many varieties of the above condition from a histological and pathological standpoint. Histologically, they consist of (a) epithelial and endothelial growths; (b) connective tissue growths; (c) lymphoid growths; (d) vascular growths; (e) nerve tissue growths; (f) chylangoma. [T. M. T.]

2.—C. W. Heitzman recommends the use of soda cacodylate as a substitute for arsenic, and states that some of the reasons why arsenic does not always give the looked-for results is because it is given in too small doses and not continued long enough. The preparation of sodium cacodylate after five years' trial seems to exercise a beneficial, stimulating and tonic effect on all patients who took the drug. It is advised, especially in cases where large doses of arsenic must be given, and is absolutely safe even in massive doses, being non-toxic in comparison with other arsenical compounds. It is given hypodermically in doses of from one to one and one-half grains daily. By the mouth and rectum it can be given up to six grains daily. No matter in what way it is given the "garlicky" odor on the patient's breath is present in from three to seven days. [T. M. T.]

3.—C. D. Hill gives some of the various avenues for the entrance of bacteria into the peritoneum: (1) Any injury or disease of the alimentary canal sufficiently intense to cause a perforation, notably appendicitis and less frequently ulcers; (2) Any obstruction, such as invagination, intussusception, or strangulated hernia, which causes a necrosis of the gut; (3) Septic conditions of the abdominal or pelvic organs, such as abscess of the liver or kidneys, and especially disease of the Fallopian tubes, giving rise to pelvic peritonitis; septic conditions of the postpartum uterus, giving rise to puerperal nephritis, this latter often being classified under a distinct heading: (1) Traumatism from within or without the lumen of the bowel, or traumatism to the abdominal wall, such as penetrating injuries caused by gunshot or stab wounds, or traumatism caused by operations. [T. M. T.]

5.—H. H. Stoner, in his article on The Etiology of Melancholia, gives his opinion of its production. He believes that the stimuli which gives rise to these painful sensations is found in tissue metabolism. Melancholia is preeminently an emotional disease, and the emotions arising are invariably of a painful character. Now, if it can be established that the metabolic process is answerable for the normal emotions, he believes that we may have here the foundation laid for the so-called abnormal emotions attendant upon melancholia. [T. M. T.]

THE NEW YORK MEDICAL JOURNAL.

August 17, 1901. (Vol. LXXIV, No. 7.)

1. The Relative Merits of Bipolar Version with Slow Extraction and Accouchement Force in the Treatment of Placenta Praevia. Report of Fourteen Cases. HENRY D. FRY.
2. The Present Status of the Surgery of the Prostate. WILLIAM N. WISHARD.
3. Infection Spread by Domestic Pets; Resemblances Between Diseases of the Lower Animals and the Human Subject. WILLIAM B. MEANY.
4. Hot Air as a Therapeutic Agent. ORRIN S. WIGHTMAN.
5. Dysentery in the Philippines. M. H. BOWMAN.
6. Antisepsis in Throat and Nose Surgery. HENRY WALLACE.
7. Some Observations on the Relation of the Alkaliescence of the Blood to the Urinary Reaction. HEINRICH STERN.

1.—H. D. Fry, in his article on The Relative Merits of Bipolar Version with Slow Extraction and Accouchement Force in the Treatment of Placenta Praevia, calls attention by his table to the large proportion of primiparae: seven out of the fourteen cases reported, or fifty per cent. Bipolar version and slow extraction were employed nine times; membranes ruptured and delivery left to nature, once; tampon and natural delivery, once; forceps extraction, four times, including one application to the after-coming head following bipolar version. All of the mothers recovered, and five out of the fifteen infants were born alive. Of the children lost, two (twins) were not viable; one was at the seventh month, and four were dead when the case came under observation.

[T. M. T.]

2.—In the present status of the surgery of the prostate, W. N. Wishard comes to the following conclusions: That the operative procedures are of the greatest values when undertaken early, and that where they are long deferred, serious resultant bladder, urethral and renal diseases make the outcome increasingly dangerous. It should also be remembered that where the catheter has failed to give adequate relief death is reasonably certain to occur very soon, especially in cases where the urethra has greatly increased in length by the elongation of its prostatic end unless the suprapubic opening for either prolonged drainage or for the removal of the obstruction is done. If the symptoms are not of a severe type and are not amenable to catheter, and if the length of the urethra from the meatus to the point where the urine is obtained does not exceed nine inches, a perineal opening generally affords opportunity for stretching the entire length of the prostate urethra, for dividing the small collar-shaped growths around the bladder end of the canal, and for removing the small projections by the finger, forceps, or cautery. One-fourth or, as asserted by some, one third of the operative cases are suitable for perineal opening. If the suprapubic operation has been thoroughly done and the obstruction all removed the patients afterward are assured of more perfect bladder function than by any other method. It must be conceded, however, that in view of the serious dangers involved, many cases should be subjected to nothing more than the formation of a suprapubic channel, as suggested by McGuire and modified by Morris. Morris's improvement lines the channel with skin, and hence it is not so apt to contract. [T. M. T.]

3.—W. B. Meany, after going quite exhaustively into the subject of infection spread by domestic pets, states that no child or person should be permitted to return to school until at least a month, or better, six weeks' time, has expired from the commencement of actual convalescence; or any one coming from a sick room until strictly modern methods of disinfection have been employed, with especial regard to personal hygiene, not only bodily, but of the wearing apparel of the individual as well. No patient, however, should be declared free from diphtheritic bacilli until at least two accurate culture tests have resulted negatively. All school books and other paraphernalia, toys, playthings, etc., or clothing that may have been brought into the sick room, or handled by the sufferer from contagious affections, or during the time of convalescence should be destroyed by incineration. [T. M. T.]

4.—O. S. Wightman sums up his paper on hot-air as a therapeutic agent as follows: Objections have been raised to dry heat, on the ground that the sedative action lasts but a short time. He says that in acute conditions we cannot hope to do more than alleviate a symptom in the acute stage, but this method is much to be preferred over the administration of a drug. Under the head of objections naturally come the elements of time, expense and convenience. As to time, there are few who would not freely devote time unlimited where there was any possibility of relief from pain. Where a chronic condition is being treated, and a full-body exposure is necessary, the time consumed in getting to the place where the bath is given, the necessity for special clothing, and the actual time consumed in the bath, with the possibility of subsequent chilling after it, all very properly enter as factors in considering this as a method of treatment. The expense, in the event of a full-body bath, with the addition of an attendant and massage, is a considerable item. In the treatment of joint affections, the Betz apparatus is very satisfactory, is easily moved from place to place, and should not be a serious monetary consideration. As to convenience, after a few intelligent observations on the part of those seeking treatment, hot air in almost every case can be administered without any difficulty whatever. There are few people who will make treatment a matter of duty if chance for improvement is held out and, with the prospect of relief at hand, gladly follow up a prescribed course of instructions. The author gives these advantages: (1) Dry heat is a valuable pain-reliever without any of the depressing effects common to drugs; (2) In connection with constitutional and medicinal treatment, we have in it a positive curative agent; (3) It is a stimulant to rapid repair and absorption; (4) It is one of the most valuable eliminative agents we possess; (5) Where indicated it possesses a sedative action on the nervous system obtained by no other means. [T. M. T.]

5.—M. H. Bowman has found that dysentery in the Philippines has been of such a character as to make the following facts advantageous: (1) dysentery, as it is seen here, is not a single, but consists of two distinct and separate diseases; (2) Acute dysentery does not produce abscess of the liver, nor does it produce ulceration of the colon. Its fatal result is due to inflammation of the bowel, rapid elimination of the watery fluids of the body, toxemia and exhaustion, much after the manner of cholera, though requiring four, six, and twelve days before its termination or crisis; (3) Amebic dysentery differs from acute dysentery anatomically, pathologically and etiologically. The only similarity between them is, the colon is the locus minoris resistentiae for both the bacillus of Shiga and the ameba. Here all similarity ends. The bacillus of Shiga leaves no other lesion behind, save its effect upon the mucous membrane of the colon and enlargement of the adjacent glands. The ameba of dysentery invades the three layers of the colon, producing pinched-out ulcers, or ulcers with undermined edges. It also passes to the liver and produces characteristic lesions. There are two varieties of the ameba which differ in no respect save as to size. The pathogenic variety is somewhat larger than the non-pathogenic. These two varieties of the ameba have been the cause of all the confusion regarding the ameba as an etiological factor in amebic dysentery. Finally, in regard to the dysenteries produced by the Shiga bacillus and ameba, he gives the following considerations: (1) The duality of dysentery is proved; (2) Acute dysentery is the result of infection with the bacillus of Shiga; (3) It is infectious in the same way as the bacillus of typhoid fever is infectious; (4) Amebic dysentery is caused by an ameba; (5) There are both a pathogenic and a non-pathogenic ameba, which fact has produced much confusion regarding the ameba as an etiological factor; (6) The lesions of amebic dysentery differ from those produced by the bacillus of Shiga; (7) The therapeutic agents generally used for the treatment of acute dysentery are in no way curative; (8) Magnesium sulphate should be included in this list; (9) Quinine solution is a specific for the amebic dysentery, but its employment in rapid, acute, ulcerating cases is fraught with danger, and from the nature of the lesions it cannot be retained for a sufficient length of time to produce beneficial effects. [T. M. T.]

7.—H. Stern concludes his article on the Relation of Blood Alkalescence to Urinary Reaction as follows: (a) The higher degree of urinary acidity concurs with a lessened blood alkalinity and the increased alkalescence of the blood with a decline of the urine's acidity; (b) There is no permanent and absolute relation between blood alkalescence and urine acidity; (c) The blood, under normal conditions, possesses a certain inherent alkalinity. The degree of alkalescence possibly varies slightly for certain periods of the 24 hours, but the influence of the ingesta upon these variations is neither a material one nor one always determinable; (d) The degree of blood alkalinity is normally not affected by the quantity of the ingesta. The quality of the nutritives may normally contribute toward the rise and fall of the blood's alkalinity, but only to a very limited extent; (e) A portion of the substances elaborated from the nutriment will be digested without having been conveyed to the blood; (f) Some of the nutritive material, isolated and not utilized in anabolism, may be transferred into the urine in a more direct manner, and thus the accidental variations in the urinary reaction may be partly explained. [T. M. H.]

1. Address in Medicine, JAMES F. GOODHART.
2. Demonstration of a Model of the Abdominal Viscera.
THOMAS DWIGHT.
3. The Origin of Oxalic Acid from Protein and Protein Derivatives, ARTHUR E. AUSTIN.

3.—Austin's studies have led to the conclusion (1) that oxalic acid is derived from the carbohydrate group in albumins, presumably through the intervention of glycocholic acid by a process of splitting, through which the remainder is converted to urea, a vital process though limited by strong oxidizing agents. (2) That oxalic acid may also be derived from uric acid by fermentative action and oxidizing agents, and

perhaps also by vital processes. (3) That oxalic acid, present in many organs of the body, practically absent from the feces of animals fed on nonoxalic acid containing foods, yet ever present in the urine after long periods of fasting, may rightly be called a metabolic product and rightfully take its place with acetone, lactic acetoacetic and oxybutyric acids as a measure of abnormal retrograded metamorphosis. [J. M. S.]

9. Two Cases of Suppuration of the Parotid Gland with Pus in the External Auditory Canal. FRANCIS R. PACKARD.
10. Tropical Diseases. RONALD ROSS.

1.—Downes remarks in speaking of **Electrothermic Hemostasis in Surgery** that with the development of aseptic surgery arose the necessity of hemostasis, that is, not only of a certain method of occluding the vessels but of doing it with an agent which would not add a complication to the case either immediately or remotely. No method of hemostasis generally used fulfils this definition. He objects to the actual cautery, silk ligature, the angiotribe, and even to sterile absorbable ligatures. He claims that the only practical method of obtaining heat in compressing blades in a measurable and controllable form is by electricity. Such electrothermohemostatic instruments he claims are ideal. The credit for their introduction belongs to the late Dr. Skene. Downes has improved on Skene's instruments and illustrates his article with a series of his own instruments which he has devised for use in pelvic and other surgery. Not only are they of value in hemostasis but they are also useful in occluding tubular structures usually requiring ligation, such as the vermiform appendix, the Fallopian tubes and the ureter. He records a series of 20 cases in which his instruments were employed successfully. [W. A. N. D.]

2.—Ries proposes a new operation for **retrodisplacement of the uterus**, which is in reality a shortening of the round ligaments through the vagina. The desirable points which his new method has intended to embody are the following: 1. A vaginal operation which would allow of all necessary operations on the appendages at the same time and through the same incision with that for the treatment of the retrodisplacement. 2. An operation that will preserve the mobility of the uterus so as not to interfere with possible pregnancy. 3. An operation that would not depend on serous adhesions, as these have proved unreliable. 4. An operation that required as little suturing as possible in the peritoneal cavity and still would leave no raw surfaces that might give rise to adhesions. 5. An operation that would not interfere with the physiological functions of the tubes. His operation consists of an anterior kolpotomy followed by delivery of the uterus through the incision into the vagina. A tunnel is then made through the anterior uterine wall from tube to tube and the two round ligaments drawn successively through this to the opposite side, the uterus in the meanwhile having been replaced. Traction upon the strings which are attached to the ligaments draws the fundus forward to the anterior abdominal wall, after which the sutures are tied and the vaginal incision closed. [W. A. N. D.]

3.—Martin in discussing the surgical treatment of **retroversion of the uterus** remarks that two operations have

become established in surgery as procedures of necessity in the successful treatment of persistent retroversion of the uterus. One is the operation of shortening the round ligaments of the uterus in the inguinal canal, or the Alexander operation; the other that of fixing the uterus by some means to the abdominal wall through an abdominal incision, or the operation of ventral fixation of the uterus. After describing the evolution of the two operations, he presents a method of ventral fixation devised by himself which consists of suspension of the uterus on a strip of peritoneum. This strip is taken from one side of the abdominal incision and parallel to it and is carried beneath the mucous membrane of the uterine fundus in the median line and then again secured to the anterior wall. The uterus is temporarily fixed by a small antiseptic cat-gut suture in order to remove strain upon the uterine attachment as described. He has operated successfully upon 173 cases by this method up to date. [W. A. N. D.]

4.—The patient, aged 22, had scarlet fever, followed by a severe attack of **Bright's disease** at the age of three years, from which he recovered and continued in good health up to September, 1899, when he contracted **syphilis**. Later he was attacked with **intermittent fever**. Both eyes presented a severe neuro-retinitis with lesions that were regarded as pathognomonic of Bright's disease. There were anemia, emaciation, asthenia, and cough. A pharyngoscopic examination revealed a single ulceration confined entirely to the lingual tonsil, presenting all the characteristics of a typical tertiary sore. Mixed treatment was administered with a speedy and happy result. [F. T. S.]

5.—Griffith mentions that the cardinal symptoms of enteric fever in infancy and childhood are not always present and in his article he gives an account of the symptoms during these periods of life. He mentions that there are two methods of onset in early life. One characterized by the absence of the early malaise, which is so common in the adult type, of fever and the presence of loss of appetite, slight headache, slight indisposition and fever. The diagnosis must often be made by exclusion. The second form of onset is characterized by vomiting and fever. The symptoms of enteric fever in childhood are decidedly more vague than the enteric fever of the adult, the course of the disease is shorter and the mortality lower. In all cases the spleen is probably enlarged, although this enlargement is not always discoverable. The fever is apt to begin suddenly without the step-like ascent; it runs a shorter course, constipation is more liable to be present than diarrhea. The tendency for nervous symptoms to predominate over the intestinal symptoms is characteristic of typhoid fever in children. [F. J. K.]

6. Morse discusses the **diagnosis of enteric fever in the laboratory**. He emphasizes that clinical methods of diagnosis should always be combined with laboratory methods, neither one being complete without the other and errors are liable to occur in any method. The leukocyte count and the Widal reaction are the most useful laboratory tests. Ninety-five per cent. of the cases of typhoid fever present a positive Widal reaction, which, however, seldom appears before the second week and may not occur until convalescence. When a number of negative tests appear the evidence against the existence of enteric fever is very strong. The Widal reaction occurs in other diseases, but this error does not exceed two per cent. There is absolute proof of typhoid fever when a negative reaction is followed by a positive one (with a dilution of 1 to 50). The finding of typhoid bacilli in the urine, in the blood, in the feces and in the rose spots, is a sign of little practical importance. The diazo-reaction is of comparatively little value as it is often present in tuberculosis, septicemia and other febrile diseases. The leukocyte count is of special importance in distinguishing septicemia and diseases accompanied by a leukocytosis, from enteric fever. It also affords a means in assisting in the early diagnosis of perforation and peritonitis in the course of typhoid fever. [F. J. K.]

7.—Rosenthal considers the **treatment of temperature by drugs in typhoid fever**. He finds that the so-called antipyretics, the coal-tar derivatives are of value in reducing temperature, but he does not claim any particular virtue for any of these drugs and if a single remedy is used too long or if too large a dose is given there is a tendency to collapse. The well-known neutral fever mixture of the U. S. Pharmacopeia is a valuable adjunct to the Brand treatment as it produces diaphoresis. He considers the Brand method as occupying the foremost position in the

treatment of enteric fever to reduce the temperature and that other antipyretics should be condemned. [F. J. K.]

8.—Abt reports a case of **multiple gangrene** which occurred in a female twenty-one months of age. This condition developed during an attack of enteric fever. The gangrenous areas were scattered on the back, neck and extremities. The eruption at first was papular, then became pustular, and finally gangrenous. The child was under observation for sixteen days when death occurred. The autopsy revealed a prominence of the solitary and agminated lymph follicles of the intestine—ulceration was not present. An adenoma was found in the left lobe of the liver. A bacteriological examination of the gangrenous areas showed that the staphylococcus pyogenes aureus and a bacillus—probably the typhoid bacillus—were present.

[F. J. K.]

9.—Packard reports two cases of suppuration of the parotid gland with pus in the external auditory canal. The first occurred in a boy nine months old. In this case the external auditory meatus contained pus. When the pus was removed the drum was found to be perfectly healthy and the purulent material exuded from the anterior surface of the auditory canal. The parotid gland was swollen. This mass was incised and it proved to be an abscess. Under anti-syphilitic treatment the child improved rapidly. The second case occurred in a boy two years of age and developed after an attack of measles. The right parotid gland was swollen and there was a purulent discharge from the right ear. Upon removing the pus the anterior wall of the external auditory canal was found perforated. Pus also discharged into the mouth just before death. [F.J.K.]

7. The Sodium Tungstate Test for Combined Chloride in Chyme. A. L. BENEDICT.

1.—A. Jacobi contributes an article on **expectant treatment** in which he briefly discusses the views current fifty years ago. He makes a plea for a timely and energetic medication and for the suppression of the very term of expectancy as needless. Expectancy in treatment has its well defined causes. First, reliance on nature; Second, the practitioner has no clear indications, and resorts to expectant treatment, which is merely no treatment, because it is of insufficient diagnosis and prognosis. Third, the physician is not sure of the action of his medicines; not even specifics, such as quinine, salicylic acid, etc. He mentions some untoward results observed by relying upon expectancy in treatment in his own practice. He believes that the platform of the physician should be, in order to obtain indications for treatment, to first make a diagnosis. That art is becoming more accessible, and, through honest and hard work, more easy with the aid of modern methods, and the physician is to remember that most diseases have a tendency to spontaneous recovery, and also that recovery is not always complete and that invalidism should not be invited through neglect of treatment. Complications are possible as long as an illness lasts, and with every day cut short, the dangers of another typical disease are diminished. The experience of old men in the profession who claim they employ less drugs with advancing years, means sometimes an inability to master new methods of diagnosis, or the wanting knowledge of new medicines of physical remedies. There is no one treatment for a disease adapted

to every patient. There is no such thing as a uniform treatment for pneumonia or for typhoid fever, even in spite of antitoxins. We should not try to treat the name of an illness, but the patient. [T. L. C.]

2.—Daniel R. Brower makes some observations in the treatment of **acute insanity in general hospitals**. He sums up the defects in our public institutions of to-day as follows: (1) That they are most of them too large, considering that they contain both acute and chronic cases. It is physically impossible for the medical superintendent to individualize the work; he must intrust a great part of the medical care and treatment to his subordinates. (2) They are too far from the homes of many of the patients. (3) The admission to these hospitals is by cumbersome, antiquated and unscientific methods, often subjecting the patient to a severe ordeal that sometimes does serious damage physically and mentally, and diminishes proportionately their chances of recovery. (4) In some of the commonwealths of this great nation, noticeably in the State of Illinois, these institutions have been degraded to the position of political machines, their organizations used to carry elections, to defray campaign expenses, and to reward those who have rendered some special party service. The New York Lunacy Commission estimates that the ultimate average charge for every patient admitted to a state hospital, who is not discharged recovered or improved, amounts to about \$6000. Brower urges that the admission for the insane to these wards of the general hospital should be as free as for other patients. There is no scientific reason why a case of brain disease causing insanity should be compelled to pass through the court, and a disease of the same organ producing hemiplegia should not. He would limit the cases for general hospital treatment to the primary curable conditions. Mania, melancholia, and stuporous insanity; the secondary insanity, the psychic degeneracies, and the arrests of the development should be excluded. [T. L. C.]

3.—Woods remarks that there have been 45 methods suggested and applied to cure the condition of chronic displacement of the uterus. The majority of these operations have been discarded because they were an insuperable barrier to pregnancy and labor or disturbed the functions of other organs, or failed to retain the uterus in its proper position. He has made a study of 212 cases of **ventrosuspension of the uterus** gathered from the case books of Penrose and Beyea, the series covering a period of 8 years. Of this number 129 were completely cured by the operation. Two thirds of them mentioned gained in weight. There were 52 cases improved by the operation, and there were 30 cases which were not benefited. Sixty of the women have been examined by the operation and only in one instance has the uterus fallen back. Twenty of the women have borne children during the operation and ten have miscarried. There has been one death which was avoidable. Hernia has not followed the operation in any of the cases. [W. A. N. D.]

4.—Edwin Zugsmith reports a case of **gastritis complicated by myasthenia gastrica**, with remarks on weakness of the gastric muscle. The patient was a laborer of 52 years who four months before seeking treatment, suffered from abdominal pains, which became worse about an hour after eating. The pains were of a burning character and were situated in the epigastrium and umbilical region. There was constant diarrhea, the stools containing mucus and occasionally undigested food, but no blood. After eating he felt heavy and bloated, and belched gas and sour liquid. Appetite was poor. He would often become dizzy and fall over his work. On examination the stomach was found to extend from the liver dulness above to one and a half inches below the umbilicus. There was no splanchnoptosis of any form, and nothing was discovered by palpation. The condition of acid secretion was normal after a test meal. A treatment of lavage was used daily, and the intragastric spray was used semi-weekly to apply silver nitrate (1-500), and a pill of strychnia, quinine

and nitrate of silver was administered. Intra-gastric electricity was applied, the fuse being the combined cathodal galvanic and slow faradic. The diarrhea stopped almost immediately, and the tendency was rather toward constipation. In six weeks after treatment the stomach had retracted to its normal condition, and ten months after treatment the patient was well. [T. L. C.]

5.—W. B. Davis calls attention to the fact that bleeding may follow any of the operations for the relief of hemorrhoids. He believes this is due to insufficient division of the sphincter ani. Hemorrhoids are composed of varicose veins and connective tissue, in the author's opinion, and never contain arteries of sufficient size to give troublesome hemorrhage. In the treatment of post-operative bleeding stretching of the rectum from the anus to the ampulla is recommended. This dilates the button-hole openings in the muscles through which the veins pass, thus relieving engorgement and hemorrhage. He deprecates the use of the rectal tampon. If an artery be found bleeding it is usually due to the invasion of the muscular coat and should be isolated and ligatured. [F. T. S.]

6.—Konikow reports two cases of congenital malformation of the vagina. In the one case the anomaly consisted in a transversal septum that divided the vagina into two cavities, lower and upper; the second anomaly was a longitudinal septum which divided the blind sac from the vagina. It is easy to comprehend and explain embryologically the anomalous condition of the vaginas with longitudinal septa, but the origin of the transversal septa is not clear. They may be due to adhesion of the vaginal walls at any point during the course of growth and development.

[W. A. N. D.]

VRATCH.

May 12, 1901. (Vol. XXII, No. 19).

1. Syphilitic Endocarditis. M. I. A. BREITMAN.
2. Genu Recurvatum. A. A. VOROBIEFF.
3. A Case of Hysterical Deaf-Mutism. N. U. KUMBERG.
4. A Case of a Rare Termination of Suppurative Periapendicitis. P. D. VEINGROFF.
5. A Case of Appendicitis Complicated by Acute Parenchymatous Nephritis. I. A. V. MOLDAVSKI.
6. Directorship or Collegueship. I. I. TROIANOVSKI.

1.—From a critical review of the published cases of syphilitic endocarditis Breitman draws the conclusion that this affection is never primary, being secondary to syphilitic affections of the myocardium. It cannot be recognized during life, owing to the fact that it is masked by the primary lesion. The pathognomonic symptom of endocarditis, the murmur, as a rule, is absent in syphilitic affections of the endocardium, and if present, changes its character and location. A complete cure is hardly to be expected even if the disease is recognized and treated early. The absorption of the syphilitic lesion will lead to valvular insufficiency, or stenosis, owing to the contractions taking place. Considerable improvement, however, may result even in very grave cases. [A. R.]

2.—Vorobieff reports, in connection with a number of cases collected from the literature, 10 cases of genu recurvatum which came under his observation. Case 1: A young peasant of 18 presented a curvature of the right knee forming an angle of 115 degrees. The etiologic factor in this case was osteomyelitis. A plastic operation restored the limb to the proper position and comparative usefulness. Case 2: A laborer, 35 years old, showed a backward curvature of both legs, the right forming an angle of 170, the left of 173 degrees. The patient suffered from an inguinal hernia, gave a history of a dislocation of the hip, also of abscess formation in the right hip when he was 18 years old. The direct cause of the deformity, however, is obscure. The probable diagnosis of genu recurvatum staticum is made. Case 3: A student of 16 complained of abnormal mobility of the right knee. The right leg was in the position of varus and when bent backward at the knee formed an angle of 140-165°. The muscles were atrophied. Osteomyelitis was the primary cause in this case. Case 4: A young man of 19 had an attack of osteomyelitis followed by suppuration of the right hip, atrophy of the muscles and a backward curvature of the leg, forming an angle of 160 degrees. Case 5: A peasant of

25 sustained an injury of the lower extremities, equinovarus and abnormal mobility of the knee joints, rendering the patient incapable of walking. Both knees curved backward to an angle of 135 degrees. Case 6 is one of genu recurvatum valgum developed as a result of congenital paralysis. The curvature reached 150 degrees. Case 7: This is more properly a case of curved leg dependent on a false joint formed after a fracture of the upper third of the tibia. Case 8 was one of genu recurvatum arthropaticum in a hysterical and demented woman of 46 with a family history of insanity. In Case 9 the genu recurvatum of both legs followed Pott's disease, being due to the position of the body. In Case 10 the deformity in the left leg followed an injury to the knee sustained 8 years back. [A. R.]

3.—Kumberg reports the following case: A soldier with an inherited predisposition to nervous diseases attended the funeral of his friend, having taken active part in the ceremony. Owing to the physical exertion involved, he was greatly fatigued, and, besides, was exposed to a strong wind blowing at the time. Having partaken liberally of some "vodka," he departed. On his way home he felt severe pain in the head and side and upon arrival began to cry, then fell asleep for ½ hour. A few hours later he had an attack of convulsions accompanied by foaming at the mouth and rigidity. When seen by the author, he was found on his back with his eyes open and the pupils dilated. He could not talk, move or put out his tongue, did not answer when questioned. Pulse, heart and temperature normal. On the following day he was found sitting and crying, could neither hear nor talk. At first he had difficulty in recollecting letters (agraphia) but soon began to write. A suggestion was made in writing that at 5 o'clock he will commence to talk. At the appointed time he pronounced two words ("who is here"). On the following day he asked for a drink. A day later he showed paresis of the right hand. Four days later he presented anesthesia and analgesia of the entire cutaneous surface. A needle pierced through the skin caused no sensation. Sensations of heat and cold were preserved. He could not open his mouth, could not hear the ticking of a watch applied close to the ear. On the following day he reported that his hearing in the right ear was restored for a "minute." Had pain in the legs, hands and abdomen. The following visit found him lying with eyes closed and in distress. Had a vision that his nose was bleeding and that he was going to die. His right hand was better, but paresis now occurred in the left. Had several attacks of pain on the following day. Lost consciousness once. The following visit found him much improved. From that time on he began to improve gradually and recovered completely in about 8 weeks, except for a slight anesthesia of the throat, the latter having been markedly insensible during the attack. The treatment was largely suggestive in character, towards the end faradization was employed.

[A. R.]

4.—Veingroff reports a case of suppurative appendicitis in which recovery was brought about by the circumscribed abscess discharging into the cecum. On the 15th day of the disease the entire appendix, together with pus and blood, was evacuated. A similar case was reported by O. O. Motchutkovski at the Sixth Congress of Russian Physicians in Kieff. [A. R.]

5.—Moldavski reports a case of appendicitis complicated by acute parenchymatous nephritis. He explains this complication by the supposition that the toxins generated by the virulent coli communis irritated the epithelium of the kidneys. [A. R.]

6.—Troianovski points out the evils which may and do result from the system of placing the entire management of the hospital in the hands of one man, the director. He makes an appeal for a council in which each member of the hospital staff should be represented, and questions relating to the medical affairs of the hospital decided by a majority. [A. R.]

EDINBURG MEDICAL JOURNAL.

June, 1901.

1. The Natural and Artificial Mineral Waters of Nauheim. Their Physiological and Therapeutical Effects and Their Employment in Disease by the Schott Methods. J. MCGREGOR ROBERTSON.
2. The Rational and Comprehensive Study of the Hepa-

tic System. FREDERICK T. ROBERTS.

3. The Treatment of the Cough in Pulmonary Consumption. ARTHUR LATHAM.
4. On Enlargement of the Spleen in Cancer of the Liver. C. O. HAWTHORNE.

1.—Will be abstracted when finished. [J. M. S.]

2.—The practitioner is in constant danger of forgetting that the hepatic system includes other structures beside the liver, and is consequently liable to frequent misapprehensions and errors in diagnosis.

The hepatic apparatus includes, (1) the liver, with its capsule and peritoneal investment and the ligaments by which it is supported, (2) the gall bladder, (3) the bile ducts, hepatic, cystic and common, (4) the hepatic artery, the hepatic vein, the portal vein and its tributaries. Morbid changes affecting the lymphatic glands in the portal fissure, or the capsule of Glisson and cellular tissue, have to be borne in mind as possible causes of symptoms, by pressing upon the bile ducts or bloodvessels, or perhaps upon nerves. It is highly desirable and advantageous to study the hepatic system intelligently as a whole, and on a comprehensive basis, from all aspects—pathological, etiological, clinical, and therapeutical—and not merely to fix attention on the liver. That the liver is liable to "functional disorders" cannot be questioned. What the exact nature of the disturbance may be is by no means always easy to determine, and the use of such expressions as "sluggish liver," "torpid liver," "disordered liver," "weak liver," and the like, in common use, even amongst the members of the profession, have really no definite meaning. "Congestion of the liver" is another expression that is in common use, but really, in the majority of cases, without any definite meaning. On the other hand, the fact must be emphasized that under certain circumstances congestion is a very important morbid condition, either acute or chronic, and if long continued it leads to further changes in the liver. Roberts feels sure that not a few cases of supposed "disordered liver," "biliousness" and the like are in reality cases of gallstones. An important aspect of morbid conditions of the hepatic apparatus is the frequency with which two or more exist in combination in the same case. There is a common belief that a strong hereditary or "family" tendency to "liver disorders," or actual hepatic disease may exist, but there seems to be no real foundation for this opinion. The more or less avoidable causes of hepatic affection include those associated with climate and meteorological conditions; errors in diet, especially habitually eating too much, indulgence in excess of meat or fat, or in rich dishes; abuse of hot condiments; intemperance as regards alcohol; want of exercise; and general luxurious and indolent habits. The hepatic system receives, as a rule, but scant attention in cases of the acute specific diseases with which we are familiar in this country, and yet several of these affections may lead directly or indirectly to morbid conditions of different kinds connected therewith, which are either in immediately serious, or lead to more or less permanent damage, the effects of which are revealed later on. It is very probable that some cases of cirrhotic liver in young subjects, which cannot otherwise be accounted for, have thus originated, and careful inquiry in this direction may perhaps clear up the etiology in such doubtful cases. There can be no doubt that disorders and diseases of the stomach or intestines often affect the hepatic system secondarily, and may thus lead to more or less serious damage. Injury of the liver may result from persistent neglect of a healthy action of the bowels. Indeed, the hepatic functions may be materially helped by getting rid of accumulated feces and by taking pains to prevent constipation. Moreover, neglect of the bowels is undoubtedly a frequent and potent factor in the production of gallstones. Pronounced jaundice, ascites, or both, have been regarded as due to primary diseases of the hepatic structures, and treated from that point of view, when really resulting from some neighboring morbid condition, which has pressed upon or implicated the bile duct, portal vein or both. These remarks apply more particularly, but by no means exclusively, to pancreatic disease, especially of a malignant nature, but it may be mere chronic pancreatitis; and to peritoneal changes, leading to adhesion and thickening. Secondary pathological effects associated with the hepatic structures often follow, and are the more or less direct consequences of venous intrathoracic morbid conditions, especially certain affections of the heart or pericardium. In cases of supposed enlarged liver, the organ is, in many

instances, not enlarged at all, but "displaced" downwards by a thoracic condition. (Rumon). A discussion of the symptomatology of diseases of the hepatic system follows. Roberts calls attention to the fact that in some affections of the liver, even of a pronounced character, anything like definite symptoms are entirely absent. Any interference with the hepatic or common duct or with the portal vein, is most likely to attract attention at once. The first step that suggests itself in any case in which there is reason to suspect the existence of any morbid condition of the hepatic system is to make a personal examination by the ordinary physical examination by the ordinary methods. The chief abnormal conditions to be looked for in the urine are, the presence of bile, an excessive discharge of uric acid and urates, deficiency or excess of urea, glucose, albumin, leucin and tyrosin. [J. M. S.]

3.—The cough which occurs in the course of pulmonary tuberculosis may be caused by reflex irritation, by the necessity of removing accumulated fluid, and by conditions other than, though often dependent upon, the original disease. In the latter class belong cases of cough due to chronic catarrh of the pharynx, tracheitis, laryngitis, intercurrent attacks of bronchitis and the like. The cough is not likely in all cases to be remedied or relieved by means of expectorant mixtures, and its routine treatment by means of anodynes is not based on very sound reasoning. Latham holds that it is not absolutely necessary that a patient suffering from tuberculosis should have a cough. In the treatment of the condition the first requisite is to place the patient, as far as possible, under ideal conditions for the treatment of the original disease. These conditions are well known. Some patients, however, cannot live under these ideal surroundings, even for short periods of time. In such cases our main efforts must be directed toward the improvement of their general condition and toward increasing the resistance of the tissue cells to the tuberculous and pyogenic microorganisms. The author recommends for this purpose the use of cod-liver oil, small doses of creasote, gualacol, and creasolal. All measures at our command should be exhausted before using such drugs as opium, chloral, henbane or the bromides; great care should be used, also, in prescribing sweet syrups. The cough that occurs the first thing in the morning and is accompanied by expectoration is useful, and must never be checked by a sedative. On the contrary, it may be aided by the use of some warm drink before the patient rises. When the cough is dry and hacking the condition of the upper air passages should be investigated with great care. If it is due to disease of the larynx, nothing does so well as fresh air at an even temperature. If we are forced to give drugs we may use a 2% solution of cocaine as a laryngeal spray. Inhalations of oil of peppermint or menthol, or local treatment with a 30% solution of lactic acid. If the dry hacking cough is due to pleuritic irritation, and if the pleurisy is at the apex of the lungs, nothing is better than counterirritation with iodine or a blister; if the irritation is basal nothing succeeds so well as effective strapping of the lower part of the chest. In other cases, incessant hacking cough is often kept up by the irritability of the nervomuscular mechanism of respiration. In such cases, food, stimulants and nervous sedatives are the best remedies. In some cases, the cough may be due to a reflex irritation from the stomach. Then gastric sedatives or counter irritation to the epigastrium or a gargle of fresh effervescent soda water will be found to give relief. When the cough is due to some associated catarrh of the larger bronchial tubes, an alkaline mixture containing ammonium carbonate or potassium iodide may be used. In the later stages of tuberculosis, when cavities are present, the accumulated secretion may be gotten rid of by the use of creasote in the form of vapor, small doses of creasote or its derivatives or turpentine. In the final stages of the disease opium often has to be used. [J. M. S.]

4.—Carcinoma of the liver exists without nodulation, without pain, without tenderness and without enlargement of the organ; just as it may pursue its entire course unaccompanied by either jaundice or ascites. The diagnosis must rest upon a review of all the facts of the case, and may be justified even though one or more of the characteristic features of the disease be entirely absent. Furthermore, carcinoma of the liver as a clinical condition, even in undoubted cases, is attended by physical facts and general symptoms common to it and other diseased states of the liver. Enlargement of the spleen in cases of car-

cinoma of the liver is quite an unusual occurrence. There are, however, occasional exceptions to the rule, and carcinomatous tumors may be found in the latter organ as well as in the liver. Enlargement of the left lobe of the liver, however, and the development of a carcinomatous mass contiguous to, though not involving the spleen, may be mistaken for enlargement of the spleen, and thus assist in producing an erroneous conclusion respecting the condition of the latter organ. LUNDBORG.

4.—Ossipow calls attention to some of the accidents which have occurred as the result of spinal puncture, and to the fact that in many cases the pressure of the fluid was not found to be increased. He has therefore undertaken, at Oppenheim's suggestion, to test this question upon dogs. He performed 2 groups of experiments. In the first the pressure of the cerebro-spinal fluid was measured and then allowed to flow off by gravity, and in the second, actual aspiration was employed. The operation was performed on some of the dogs a number of times, and they were then killed and the central nervous system examined. The results showed that the removal of the cerebro-spinal fluid produced a persistent hyperemia of the blood vessels of the meninges, and of the substance of the brain and cord. When the punctures were repeated numerous punctiform hemorrhages appeared particularly in the upper lumbar and the lower cervical regions, and in some cases, even in the substance of the brain. When aspiration was employed, hemorrhage not infrequently occurred into the central canal. In the cases most severely treated by repeated punctures there were alterations in the nerve cells. He therefore concludes that lumbar puncture is not a trifling operation; that whenever the cerebro-spinal fluid is drained, there is danger of cerebral hemorrhage, or at least of hemorrhage into the cord. It is therefore contra-indicated in sclerosis of the blood vessels; in anemia of the cerebral blood vessels, and particularly in all acute chronic diseases of the central nervous system in which a distinct increase in the pressure of the cerebro-spinal fluid cannot be determined. Of course, if only a small quantity of the fluid is removed, the danger is not nearly so great. He does

not regard the value of lumbar puncture in cases of cerebral apoplexy very highly. Blood may be mixed with the cerebro-spinal fluid as the result of many other causes. He therefore believes that lumbar puncture should never be performed unless the indications are very clear, and that lumbar puncture with aspiration should be entirely abandoned. [J. S.]

5.—Rosenfeld has studied very carefully the temperature changes in a case of syringomyelia. The diagnosis appears to be very clear. In view of the researches of Webber, who found that when a large portion of the skin was subject to the action of heat or cold for a considerable length of time the temperature sense still persisted, he attempted to obtain the same results in this patient. The apparatus that he employed was quite ingenious. Small lead tubes were wound in the form of a spiral in a single plane, and then water of a certain temperature passed through them at considerable speed. It was found that the temperature of the water could be readily modified by adding hot or cold liquid, and that the temperature of the disks could be kept the same for an indefinite length of time. These disks were prepared in various sizes, and it was found that the largest size could usually be distinguished accurately in any parts in which the temperature anesthesia was apparently complete. He concludes that these results prove that there is actually a summation of stimuli in the sense of Webber, that is to say, very faint stimuli coming from numerous points are capable of causing the sensation of heat and cold. But as the patient was able to distinguish very accurately between a hand that had been artificially cooled, and one that had been artificially warmed, although the temperature difference was less than the minimum that could be distinguished in the disks, Rosenfeld believes that perhaps another explanation is possible. However, he admits that the hand is capable of applying itself more closely and thoroughly to the part tested. [J. S.]

6.—Lapinski and Cassirer have extirpated the superior cervical ganglion in 5 rabbits, and the inferior cervical ganglion in two. Five of the animals were killed in a period of from 14 to 16 days after the operation, and two 3 weeks later. The spinal cords were then removed and stained in serial sections, partly by the Marchi method, and partly by that of Nissl. The results were entirely negative, and they therefore conclude that the origin of the sympathetic nerve in the spinal cord is as yet an unsolved problem. [J. S.]

7.—Lenaz discusses ataxia, and calls attention particularly to certain facts in the ataxic gait. First, the flexion at the knee is not controlled in such a manner as to produce the greatest economy of energy. When the leg has reached its maximum height in the step, the flexion of the knee continues, and therefore at the end of the step the foot is abnormally high and falls strongly upon the ground. He therefore looks upon ataxia as a loss of the synergetic influence of the various joints. Against the theory that ataxia is produced by interference with the centripetal tracts is the fact that in many cases it may exist without any disturbance of this nature. Lenaz believes that even although the patient should feel perfectly well what degree of innervation he should impart to his muscles, it would be impossible to carry out coordinated motions unless each detail of the movement were perfect. He therefore concludes that there are probably 2 systems concerned in movement. First, that of the cerebrum which consists of the sensory fibres to the brain, and the motor fibres from the central region. Second, the cerebellar system which supplies the involuntary and unconscious but nevertheless, indispensable synergies. Disease of the cerebral system causes in general paralysis, of the cerebellar system ataxia. [J. S.]

8.—Biro reports 5 cases of Friedreich's ataxia. The first, a boy of 2 years, had the characteristic symptoms with the exception of normal knee-jerks, and Achilles ten-

don reflexes. A brother of 7 years had similar symptoms. There were marked ataxia, slight nystagmus, and the reflexes were diminished or lost. A third brother 15 years of age, was said to have suffered from the same disease. The 3d case, a girl of 18, with slightly impaired intelligence, noticed the first symptoms, tremors of the hands, some time before her 12th year. Subsequently she had extreme ataxia, Romberg's symptom, some intention tremor, and loss of reflexes. The 4th case, a woman of 40, developed the disease after pregnancy. There was marked ataxia, slight nystagmus, and loss of the reflexes. She had suffered from severe pains in the limbs. In the 5th case, a boy of 16, there was ataxia, loss of reflexes, peculiar deformity of the foot, Romberg's phenomenon, imperfect articulation, slight disturbance of sensation, and slight nystagmus. In the early stages of the disease he had had convulsions. The author quotes freely from the literature, and has prepared an elaborate table for the differential diagnosis of Friedreich's disease and the following conditions. The diseases of Moebius, of Nonne-Marie, tabes dorsalis, chorea, multiple sclerosis, hereditary spinal paraplegia, hereditary atactic paraplegia, hereditary syphilis, cerebellar disease, progressive muscular atrophy, progressive spinal muscular atrophy, and progressive neuro-muscular atrophy. The table however, is incomplete. [J. S.]

9.—Biro reports a number of cases showing the various changes that occur in the **Achilles tendon reflex in tabes dorsalis and sciatica**. He concludes that the existence of healthy persons without tendon reflexes is very doubtful, and it is still more so whether a tendon reflex can be absent in a healthy person from birth. In many cases of sciatica Achilles tendon reflex was impaired on the diseased side, but never on the healthy side. In some cases, in the very commencement of the disease there was slight impairment of the reflex on the diseased side, and therefore the dependence of the Achilles tendon reflex upon the sciatic nerve appears to be justified. In tabes dorsalis, in the early stages of the disease one Achilles tendon reflex may be affected, but later in the course both always disappear. In one case of general paresis he observed that on one side the Achilles tendon reflex was diminished. [J. S.]

10.—Mohr has studied the **tendon reflexes of the upper extremities upon 90 soldiers**, with the following results. The triceps reflex was present in 60 cases; the supinator in 78; the triceps was absent on both sides in 15 cases; absent on one side and diminished on the other in 2 cases, and absent on one side in 13. The supinator reflex was absent on both sides in 9 cases, and on one side in 3 cases. He has studied 22 cases of tabes dorsalis and found that the knee-jerk was absent in 16. In 7 of these the triceps was lost on both sides, and in one case, on one side. In the others the triceps was either normal or increased. The supinator was present slightly often. He also reports the case of a man 19 years of age, in whom the triceps was lost, the knee jerks preserved, and at the autopsy a cervical tabes was discovered. He reaches the conclusion that the tendon reflexes of the upper extremities are inconsistent, their absence is of no value in diagnosis, that they occur in about the normal frequency of occurrence in tabes dorsalis, and that only when they are normal or exaggerated can they be regarded as of diagnostic significance. In which case a distinction between functional and organic disease can be made by the detection or absence of increased muscle tone. [J. S.]

11. Giese reports a case of **tumor pressing upon the spinal cord**. It involved the lower portion of the medulla, and the third upper cervical segment on the right side, allowing a small slit through which the medulla and cord could pass. The greatest deformity was in the cervical portion of the cord below the third segment the cord seemed to be normal in consistency and appearance. A microscopic examination however, showed, as was to be expected, the degeneration in the pyramidal column, and areas of de-

generation in the posterior column corresponding to the comma degeneration of Schultze. This however, continued for only 3 segments and then disappeared, and could not be followed further by the Marchi method, apparently confirming the belief of Gombault and Philippe, that the fibres concerned in this degeneration have a very short course. The fact that this degeneration was unilateral indicates, according to Giese, that the fibres probably represent descending fibres of the posterior roots. [J. S.]

12.—Spitzer reports the case of a man 28 years of age, who had had several injuries, and at one time an eruption on the skin. When admitted to the hospital there was a macular papulo syphilitic on the trunk and extremities, besides local lesions. He was extremely anemic, and therefore was at first given syrup of the iodide of iron, and later mercurial inunctions were instituted. The patient rapidly developed diarrhea and stomatitis. Treatment was then discontinued, then recommenced, and the patient began to complain of pains in the limbs. Examination showed diminished motor power in the muscles; he had extreme ataxia; the tendon reflexes were increased; Romberg's symptom was present, but the pupils, and the bladder and rectum reacted normally. Cessation of the treatment caused rapid improvement. Acute mercurial polyneuritis is a very rare condition. Spitzer collects and analyzes 8 cases from the literature. [J. S.]

13.—Wallenberg reports the following interesting cases. A woman suffering from extreme arterial sclerosis had an apoplectic attack without loss of consciousness. Subsequently she presented the following symptoms. Vertigo, feeling of cold in the right temporal region, and difficulty in swallowing. Examinations showed disturbance of sensation, particularly of pain and temperature in the distribution of the 2 branches of the right trigeminal, dissociation of sensation on the back of the left hand, and the lower portion of the left thorax, involving the left leg. The right vocal cord was paralyzed and there were atactic movements of the extremities on the right side. He diagnoses thrombosis of the posterior inferior right cerebellar artery. The second patient, a man of 61, after severe exertion had weakness and tingling in the left foot. In the course of a few hours there was vertigo, difficulty in swallowing and speaking, and disturbance of sensation, and finally weakness in the right arm. Eight years later there was diminution of touch and temperature sense in the three branches of the trigeminal, total paralysis of swallowing, paralysis of the right vocal cord, atrophic paralysis of the right arm, trophic disturbances, atrophic paralysis, contractures of the left leg, and diminution of the reflexes on the left side. The whole left side of the body showed dissociation of sensation. A diagnosis was made of thrombosis of the right vertebral artery, commencing at its origin, from the right inferior posterior cerebellar artery. The 3d case, a man of 48, who had had syphilis, had an apoplectic attack without loss of consciousness but with vertigo and vomiting. The following symptoms persisted. Vertigo, a tendency to fall to the left, ataxia of the left leg, loss of the patellar reflexes, nystagmus upon looking toward the left, difficulty in hearing in the left ear. The diagnosis is difficult but Wallenberg believes that an acute lesion of the left restiform body is most likely. The 4th case, a man of 70, had an apoplectiform attack and mentioned curious sensations in the nose, and tinnitus in the right ear. Later there was paralysis of the right side of the face, deafness in the left ear, and trophic disturbances on the right side of the face. There was loss of pain sense in the distribution of both trigeminal nerves; paresis of the muscles of mastication on the right side; complete paralysis of the right abductors, and diminution of pain sense in the left neck, breast and shoulder. There was slight increase in the tendon reflexes in the left leg. The most likely diagnosis is hemorrhage into the right half of the pons between the sensory nuclei of the trigeminal. [J. S.]

14.—Von Sarbo reports the case of a man whose occupa-

tion was casting lead, and who from his 20th year gradually developed atrophy in the muscles of the body. Electric examination showed diminution of galvanic and faradic irritability, and some of the muscles refused to react at all. The patient had been working in lead from his 13th year. He had had several attacks of lead colic. Sarbo regards the case as one of spinal muscular atrophy, particularly in view of the fact that the patient was able to continue working until disabled by tuberculosis; whereas in acute poliomyelitis due to lead, inability to work comes suddenly. He believes that the lead disturbs the nutrition of the whole body, and affects particularly those parts which, as a result of intoxication, or for other reasons, constitute areas of lessened resistance. [J. S.]

15.—Finkelnburg reports the case of a man many of whose ancestors and immediate relations had died of tuberculosis. He acquired at the age of 42, a hard chancre, was extremely depressed about it, and 3 months later developed left-sided hemiplegia, after some prodromal symptoms that indicated involvement of the brain. Two months later he had a severe headache that yielded to specific treatment. A year after the infection and six months after the first symptoms he developed right-sided hemiplegia, followed by symptoms of paralysis of the vagus and death. At the autopsy in addition to a catarrhal pneumonia of both lower lobes there were found extensive changes in the arteries and veins of the central nervous system and its meninges, characterized by thickening of the interna, and round cell infiltration of the pia in the base of the brain and in the region of the right frontal lobe, and in the spinal cord. There were also inflammatory changes about the nerves at the base of the brain and about the roots of the cord, and finally an area of softening in the lenticular nucleus and in the pons. The difficulty in this case consisted in the discrimination between syphilitic and tuberculous lesions of the blood vessels. Arterial sclerosis is excluded on account of the age of the patient. However, the clinical course of the disease is strongly in favor of syphilis, and as all the symptoms could be explained by the lesions found; Finkelnburg concludes that the process probably was syphilitic in nature. [J. S.]

16.—Lundborg, as the result of a study of 2 cases of myoclonus, became convinced that they depended in some way upon alterations of the function of the thyroid gland. It also occurred to him that as the rigidity of the muscles is such a prominent symptom in paralysis agitans, it must also be due to condition of this kind, and that their treatment with thyroid extract would possibly be indicated. He reports the case of a woman, 54 years of age, always weakly, and in middle life very stout, who had attacks of biliary calculi with jaundice. Symptoms of paralysis agitans commenced at the age of 46, the first symptoms being a tremor of the left ring finger and of the toes of the left foot. Then pain appeared in the left arm and leg, the tremor became more severe, and involved the muscles of the breast and abdomen. The movements became stiff, and finally weakness was so severe that the patient required support when moving. At the same time certain other symptoms occurred. The patient became querulous and melancholy; the hair became thin; the eyes somewhat smaller; the features coarser and larger, and there was transitory edema in various parts of the body. The appetite was good and the patient from time to time had boulemia. Later the lower jaw became more prominent, and the teeth were separated. From time to time she had chilly feelings, and tremors of the whole body, and finally enormous thickening of the skin of the legs occurred. Intelligence gradually decreased and there was considerable loss of powder. Lundborg considers the case as unquestionably one of paralysis agitans and that the other symptoms resembled those of myxedema. He also mentions a case of exophthalmic goitre in which symptoms of myxedema were present. Before the paper was published the patient died, and at the autopsy a moderate chronic pachymen-

gitis around the cerebrum and a small tumor in its substance were found. The thyroid glands were small, the hypophysis was normal. Microscopically the thyroid gland showed symptoms of atrophy. Lundborg concludes that it must have been insufficient. [J. S.]

31.—In those cases of narrow stricture, situated low down in the esophagus, in which gastrostomy must be performed, much depends upon whether even a small instrument will then pass through the stricture. If this first effort meets with success, all will probably go well. Alapy reports the case of a boy of 7, with two strictures of the esophagus following the ingestion of lye. The upper stricture could be passed, but the lower, just above the cardia, would not let even a filiform bougie by. Gastrostomy was performed. A week later, an elastic bougie was introduced through the stomach up to the site of the stricture, and a silk catheter was passed over it. Then the bougie was withdrawn, and a filiform inserted, which easily passed through the stricture and out to the mouth. After that, dilatation was accomplished quickly, and the child recovered. Alapy devised this method to overcome two difficulties: finding the cardia, and passing the stricture. As ordinary filiform bougies are not long enough, he advises the use of the Phillips bougies. [M. O.]

32.—Franke divides his researches in the treatment of complicated fractures into two parts, those of the extremities, and those of the skull. Modern aseptic treatment has made these wounds much less dangerous than they formerly were. In every case he tried to keep the wound aseptic, to put the fragments in good position, to keep up absolute rest, followed, after healing, by regulated movements. The region of the wound was disinfected, and if the wound was small, and contained a foreign body, it was removed, the wound dried out with sterile gauze, and a sterile dressing applied. In large wounds, counterincisions, drainage, removal of splinters of bone, etc., followed, but washing out with antiseptics was never done. Large pieces of bone were saved, sharp edges being sawed off first, to prevent pressure on the blood vessels, and gangrene. When dislocation seemed imminent, bones were sutured together with silver wire. Attempts were made to cover the bone with soft parts. The injection of a little iodoform-ether, and drying with sterile gauze, completed the treatment. With this many limbs escaped amputation. Even when gangrene was feared, conservative treatment was carried out. Yet some cases had to be amputated. Immobilization was secured by plaster bandages, extension, or splints. Roentgen photographs were taken regularly. The fractures of the skull were treated in much the same way. Wounds were generally enlarged, to see the amount of damage done. Even a greater attempt was made here, to make the surface smooth. Many blood vessels of the dura and pia were ligated. Where parts of the brain were badly injured, they were removed, as were foreign bodies, splinters etc. If possible, clefts in the dura were sutured. Great care was taken to prevent bone defects. The bone was replaced, after being washed in a boric acid solution, and the skin closed over it. Osteoplastic resection was necessary in some cases. The histories of 73 complicated fractures of the extremities, and of 24 complicated fractures of the skull are given in detail. [M. O.]

33.—Wolff reports the rare case of a carcinoma occurring in the wall of a closed dermoid cyst. He could find no similar case in literature. A Russian, aged 21, had always had a small tumor over the inner canthus of his left eye. This had increased in size during the past two years, but never caused any symptoms. It was elastic, but did not

decrease on pressure. A typical dermoid cyst was removed with difficulty, on account of its attachment to the pericæcum. Some of the surrounding connective tissue was removed with it. Microscopical examination showed carcinomatous degeneration of the cyst wall. He reports a similar case following the removal of a dermoid cyst of the sacrum. In both cases carcinomatous changes occurred in dermoid cysts. In one, closed and intact. In the other, upon the remaining wall left after excision of the cyst. [M. O.]

34. Kelling speaks of the prejudices against the use of the Murphy button in gastro-entero-anastomosis. Yet he considers that a good anastomosis button will resemble the Murphy button, for it must remain unchanged until the necrotic intestinal wall has been thrown off, and then be wholly digested in the stomach or intestines. Kelling has constructed a button from ivory that has been deprived of its calcium. It is in one piece, a cylinder with funnel-shaped ends, covered with rubber as a protection against the digestive juices. This covering is absent in the deep outside groove where the stitches will be placed. It is fixed in place by two sutures. Its application is fully described, with attention to every detail. A number of experiments on animals follow to show its usefulness. For operations on the colon, Kelling has devised a wooden button, which he has used in dogs. Kelling has also employed absorbable plates of bone or ivory from which the calcium has been removed. [M. O.]

35. Hugel reports three cases of colon tuberculosis in which operation was necessary. In the first the mass was in the iliocecal region; in the second, in the ileocecal region ascending and transverse colon; and in the third in the right colic flexure. Resection of the affected part of the intestine, with anastomosis, was performed. Two of the patients recovered, while the other died. Microscopic examination confirmed the diagnosis of all three cases. Hugel believes that the whole part affected should be removed. Should phthisis also exist, he thinks that the intestine should be stripped for its entire length, and the exposed ends of the intestine opened. With an iodoform gauze compress the stripped intestine can be cut off from the peritoneum, and resection can be performed later, when the strength of the patient permits, without a second laparotomy. But he believes that by ligating off the mesenteric vessels leading to the exposed section of the intestine, certain involution of the tubercular process will follow, and perhaps save later resection. [M. O.]

36. Grosse reports the case of a girl of 5, whose right leg, especially below the knee, was markedly smaller than the left, even at birth. Nor did the right leg grow below the knee. Various different supports had been used without effect. Roentgen photographs showed the absence of the tibia, the fibula being alone. Professor von Bramann operated, bringing the fibula into the knee joint, taking great care that the epiphyseal cartilage was not injured. Foot and leg were then put in plaster. With a support down the leg, about the waist and a block under the foot, she soon could run. In six weeks femur and fibula had grown together; and her leg has developed well in the two and a half years since. The former shortening of 5¾ cm. has been decreased 2 cm. She can now support herself without any splint, walking with a slight limp. Grosse reports another case of von Bramann's, with similar results, no splint now being needed. [M. O.]

37. Manasse reviews the experimental operations upon nerves before telling of his work in grafting one nerve upon the other. For a successful result, in investigations of this kind, he believes that function must be restored throughout the region supplied by the paralyzed nerve, the peripheral end of which has been grafted upon a neighboring nerve; that electricity must return; that the two nerves must grow together anatomically, which will be seen, histologically, by the continuity of the nerve-fibres. On account of its simplicity, Manasse decided to graft the facial nerve upon the accessorius, as treatment for traumatic paralysis of the facial nerve. He performed experiments upon 11 dogs, 5 of which were carried to a conclusion. Their histories follow in detail. A description of the different methods of operating is given. Manasse's results were not at all satisfactory, nor does he consider the operation an easy one. [M. O.]

7. The Pathological Conditions of Drunkenness. K. HEILBRONNER.
8. The Hygienic Conditions of the Larger Cities of Europe in Old and Recent Times. O. SCHWARTZ.

1.—Brauer, after discussing the unsatisfactory results of attempts to find definite pathological changes in the quantity and quality of the bile, mentions two alterations in its constitution that he thinks may be regarded as certain indications of pathological processes. The first is the presence of sugar. This is extremely rare, and even in cases of alimentary diabetes with 4% of sugar in the urine, glycocholia did not occur. But in experimental diabetes produced in dogs by the removal of the pancreas sugar was found in the bile almost invariably. It is not certain to what extent this glycocholia is due to the solution of glycogen in the liver. In cases of profound alcoholic intoxication in dogs, alcohol could always be obtained from the bile by distillation, a small amount of sugar was obtained in one case, and invariably there was a considerable amount of albumen. Microscopically Brauer has been able to find in the bile branching epithelial casts, especially in cases of alcoholic intoxication. He suggests that the latter may possibly be simply an inspissated secretion. [J. S.]

2.—Greife calls attention to the great superiority of the fibres obtained from the ligamentum nuchae of the reindeer over various other forms of materials employed for ligatures. In the first place the material when collected is practically sterile, there are no germs in it normally, as is the case with cat-gut. It may be readily sterilized, either by juniper oil or bichloride without losing any of its desirable qualities, and the degree of its flexibility may be preserved by placing it in water about 30°. In a moist condition it maintains its elasticity if it is not unduly stretched. It seems to act as a drain quite as efficiently as the other forms of ligature, and is much more slowly absorbed. Thus, a ligature removed 31 days after an operation seemed to be perfectly normal, but in another case 124 days after an operation no trace of the ligature could be found. In dogs a slight trace could be found in the kidneys after 122 days. No bad effects can be observed from its use, and Greife has suggested an ingenious carrier consisting of 2 test tubes, one slipped within the other, thus preventing the entrance of germs, and yet enabling the ligatures to be obtained with very little difficulty.

3.—Lieven calls attention to the great danger of extra-genital infection with syphilis upon the lips in ordinary family life, especially from the servants, and he relates cases in which such infection occurred, either as a result of the kissing of children by their nurses, or of the use of similar utensils for drinking or tasting by the cook and housewife. He believes that chancres of the lips do not resemble the ordinary genital forms sufficiently closely to enable us to make a diagnosis at a glance. He believes that there are 3 characteristic forms of lip chancre. One, in which the sclerosis is about the consistency of parchment; second, a large form covered with crusts; and the third, an ulcerated sore with suppuration of the edges. The usual associated symptoms are, of course, the enlargement of the submental glands. The most important conditions from which the differential diagnosis should be made are sores due to caustics, to cigarettes, and herpes labialis. The prognosis of this condition is good, so far as the cosmetic results are concerned. The general infection is, of course, equally severe, no matter where the original sore is located. A differential diagnostic point is the situation of the buboes. If behind the sternocleidomastoid the initial infection must be in the pharynx. [J. S.]

4.—Fuernrohr performed an autopsy upon a patient dying

of typhoid fever, and about three weeks later developed symptoms of the disease. As all other forms of infection could be eliminated, and as no other cases of the disease existed in the neighborhood, he is convinced that he was infected from the body of the patient, and he supposes that this infection was due to the small particles that were blown into the air during the washing of the intestines. [J. S.]

5.—Paulsen has had the opportunity of studying the manifestations of gonorrhea in the new-born. Of course the commonest primary infection is that of the conjunctiva; he calls particular attention to the various forms of skin lesions that may be manifested as a result of primary inoculation or of metastasis. In one instance he observed numerous papules and blisters containing gonococci, upon the skin. In another, a profuse exanthema consisting of papules and blisters, and in various other cases similar lesions. The commonest situation for this process is the head. There is no reason to suppose that prolongation of the birth increases the tendency to infection. The diagnosis is to be made exclusively by the discovery of the gonococci in the contents of the blisters, or in the pus of the conjunctiva. The general symptoms are usually very slight. Treatment consists in scrupulous cleanliness, and in opening the larger blisters. These lesions are very uncommon in adults. [J. S.]

6.—Trautmann has devised an ingenious laryngoscope consisting essentially of a small metal container, to which the handle is attached and a little cap that fits over this and retains the mirror in position. The metal parts can be boiled, and the mirror sterilized by careful polishing. [J. S.]

7.—Heilbronner concludes his article upon the pathological forms of drunkenness. Among the important predisposing causes are injuries to the head. In other cases no predisposing conditions can be detected. When more than one attack occurs in the same individual, the symptoms of the second usually resemble those of the first. Another frequent cause is sexual excess. The diagnosis is usually easy, a state of confusion, excessive motor unrest, and the other characteristic changes being present. For the differential diagnosis, from profound drunkenness may be utilized the fact that in the latter state the patients usually fall asleep at once, and in the pathological conditions it is very difficult to get them to sleep at all. The degree of amnesia that follows is very variable; usually it is complete, but not invariably so, and it is also noteworthy that amnesia may follow ordinary states of drunkenness or even epileptic attacks. Probably the most difficult differential diagnosis is from the various aberrant forms of epilepsy. The greatest importance attaches to this condition on account of the medico-legal element that many of them contain. [J. S.]

8.—Schwartz defends the hygienic conditions of Rome under the Popes, and contends that in spite of statistics, it is really little better under the civil government of Italy. He calls attention to the fact that in all countries the death rate varies very closely in accordance with the degree of concentration in the population. [J. S.]

DEUTSCHE MEDICINISCHE WOCHENSCHRIFT.

May 30, 1901.

1. Observations and Investigations Concerning Chronic Pentosuria. M. BIAL and F. BLUMENTHAL.
2. My Experience with the Bacillus of Danysz. A. KRAUSZ.
3. Contribution to the Treatment of Knee-joint Contractions. HEUSNER.
4. Cerebral Hemorrhage with Verrucose Endocarditis. M. SIMMONDS.
5. The Condition of the Blood Pressure During the Treatment of Chronic Heart Disease. SCHOTT.

1.—The authors disagree with Naunyn in his statement that the pentoses of the urine are derived from the pentosans of the food. Blumenthal has found persistent pentosuria when the food contained no pentosans. The authors made the interesting report that they gave a patient with chronic pentosuria 100 gm. of glucose without producing glycosuria, 100 gm. of levulose without any change in the urine, 100 gm. of galactose, which latter caused galactosuria to the extent of 5 gm. only—i. e., the patient had no ten-

dency to diabetes, and not even the slightest tendency to alimentary glycosuria (or mellituria of any form). The injection of 0.5 gm. of phloridzin caused the excretion of 21 gm. of fermentable glucose polarizing to the right—i. e., the patient reacted quite normally. The blood also contained a normal amount of glucose. Hence the glucose production was normal in amount and the authors decide that the affection has no evident relationship to diabetes, and must be considered a disease *sui generis*. The food taken did not influence the pentosuria, therefore it did not depend to any applicable extent on the diet. It was thought that the pentose might be derived from the body or food nucleins. This was rendered extremely improbable, however, by the fact that 500 gm. of thymus, which is extremely rich in nucleins, caused only slight increase in the pentose excretion. Pentoses were found in the blood to the extent of 0.08% (reckoned as arabinose). Hence they are not found in the kidneys. The authors then thought that perhaps pentoses are normally found in the body and oxidized there, but that this patient and similar subjects have lost the power of oxidizing pentoses; hence they gave her 50 gm. L-arabinose and were astonished to find that only 6 gm. was excreted, this meaning that the assimilative powers for pentoses taken by the mouth were normal. Hence the affection is again very different from glycosuria and diabetes, for in either of these the assimilative powers for glucose are much reduced. [D. L. E.]

2.—Krausz disagrees with Köttgen (*Deutsch. Med. Woch.*, May 2nd, 1901) concerning the bacillus of Danysz. He finds that it does not cause any striking and characteristic lesions in rats, and though it is pathogenic to these animals, it is not strikingly so, and does not cause epidemics among these animals. There is no danger, in his opinion, of confusing it with the plague bacillus, and also no hope that it can be used as a means of ridding various infested regions of rats. His opinions are based upon laboratory experiments and upon the results of placing food infected with the bacillus in sewers. In the latter case rats were not afterward found dead in large numbers as it was thought they would have been were the bacillus capable of producing fatal epidemics in rats. [D. L. E.]

4.—Simmonds reports several very interesting cases. It is known that cerebral hemorrhages often follow the development of small aneurysms, and it is also known that infested emboli lodging in arteries may cause the development of aneurysms. In several of the cases reported the development of aneurysm with subsequent cerebral hemorrhage seemed to have occurred very definitely as the result of verrucose endocarditis, and Simmonds insists that we must think much more commonly than is customary of such a series of events rather than of embolism or ordinary hemorrhage following arteriosclerosis. In three cases occurring respectively in patients 32, 45 and 50 years of age, fatal cerebral hemorrhage was thought to be the final result of the lodgment of a septic embolus because fresh endocarditis in all cases engrafted on old disease was found, and excepting for the point of hemorrhage the arteries and the kidneys also were healthy. In two further cases similar conditions existed, excepting that actual aneurysms were found at the point of hemorrhage. These were both girls, aged respectively 32 and 27 years. The most important cases, however, were those of two children, one ten and the other eleven years old. Both died of cerebral hemorrhage. Both had otherwise normal arteries, but an aneurysm existed at the point of rupture, and recurrent mitral endocarditis. Gromé-Wegert staining showed in both cases staphylococci in both the endocardial vegetations and the tissues of the cerebral aneurysms which in their staining and morphological characteristics seemed identical. [D. L. E.]

5.—To be concluded.

1.—Arnold has made a number of experiments of which the technique consists essentially in soaking thin sections of pith in various oily substances, such as milk, tallow, etc., and then placing them in the lymph sac in the backs of frogs. He concludes that the fatty particles can be absorbed by the cells in the form of small drops that lie between the structural elements of the protoplasm, and thinks that this process is akin to phagocytosis. In addition fat granules may occur in cells as the result of the modification of the plasmosomes. This is proved by their peculiar position, and their relations to the cell fibres, and particularly to the presence in the cells of granules that give the fat reaction in various degrees of intensity. He regards it as possible that the fat absorbed by the cells may in time be replaced by the modified plasmosomes. [J. S.]

2.—Erbstoh has studied five cases of carcinoma. Three of the prostate, one of the stomach and one of the biliary passages. In the primary foci of the disease there was very little tendency to degeneration. In some of the metastases bone had been found. Injection of the tumors gave rise to curious appearances, particularly in some places it seemed as if a tubular system had been injected, and that the tubes were lined with epithelium. The author suggests that perhaps the capillary system had become infiltrated by the epithelial growth. The bone was formed in the spaces between this tubular system, as a result of a capillary occlusion that gave rise to a venous congestion, and it is possible that this promoted the formation of bone. Apparently this new-formed bone underwent changes similar to those of osteomalacia. The metastases usually invaded the bone marrow and the lymph glands. Other organs remained unaffected. [J. S.]

3.—Icker reports a number of cases of hygroma, one of dermoid cyst, and two of fibroma of the uterus. All these exhibited the typical degenerative character. As a result of a careful study he reaches the conclusion that the fluid filling the cysts is formed by the gradual liquefaction of the connective tissue fibres. The blood vessels are not concerned in the formation of this fluid directly, but may produce it secondarily by themselves degenerating, and thus interfering with the nutrition of the fibrous tissue. He regards this liquefaction as identical with fibrinoid degeneration. [J. S.]

4.—Muhlmann has carefully weighed the majority of the organs in 27 men and 29 women, and gives the results in tabular form. The patients died of various diseases, and represented ages from birth to 90 years. He calls particular attention to the results obtained by weighing the intestines and lungs. He found that the absolute weight of the intestines is lowest at birth, then rises steadily until the age of 19 is reached, and then gradually diminishes until from 70 to 80 it reaches the minimum. The relative weight, however, does not vary very much, although it may be slightly greater in age than in childhood. Although as a rule the relative weight of the other organs decreases, the lungs apparently increase and decrease in weight with the rest of the body, and maintain an almost uniform proportion to the body weight, of 2 to 3%. The heart shows steady increase in weight during life. [J. S.]

5.—Coenan has injected the pleural cavities of rabbits with an emulsion of aleuronat, and studied the changes that occur at varying intervals up to 1 week. He observed the following types of cells: Pseudo-eosinophile contain-

ing numerous oxyphillic granules, the so-called true eosinophiles, lymphocytes, basophiles, desquamated and necrotic pleural epithelium cells with numerous small nuclear-like formations, in their substance. He concludes that the aleuronat emulsion produces a sterile purulent pleuritis, rapidly going on to complete recovery, reaching its acme at the end of the second day, at which time proliferation changes begin to appear. The giant cells appear on the 4th day. The epithelium of the pleura is reformed by proliferation of that remaining. The leukocytes are nearly all pseudo-eosinophiles; the protoplasm contained both oxyphillic and neutrophilic granules. The true eosinophiles are usually found in the neighborhood of the inflammatory process, and gradually increase as the pseudo-eosinophiles disappear. Both forms appear to be subject to the same chemotactic principle. In the red substances lymphocytes appear. [J. S.]

6.—Woskresensky reports a curious uterus, characterized by a peculiar cellular-like construction of the muscle wall, which, microscopically, was shown to consist of numerous small cavities lined with epithelium. The tissue between these cavities consisted of the ordinary fibrous connective tissue. The diagnosis rested between a cysto adenomyoma and cystic degeneration. It was finally decided that the latter was probably the case, because the entire substance of the uterus was involved in the process, a condition that rarely occurs in the true tumor formation, and he therefore makes a diagnosis of uterus cysticus degeneratus. [J. S.]

7.—DeMeser, while studying, microscopically, sections of an epithelioma of the right forearm, observed peculiar bodies in the interior of the tumor that were determined to be lycopodium spores. It was subsequently learned that the patient was in the habit of dressing the ulcerated surface with a powder containing these bodies. They were found either in the fibrous tissue, or enclosed in the giant cells, and in this case it was very evident that cariokinesis of the nucleus produced the multi-nuclear formation. DeMeser calls attention to the great diversity of opinion that exists between the German and French schools regarding the ability of granulating surfaces to absorb foreign bodies, and he believes that, as a matter of fact, great differences do exist, and are produced partly by the nature of the body, and partly by the dressing employed. These observations are particularly interesting because they prove that foreign bodies can penetrate deeply into tumor masses, and that various peculiar appearances in them that might be mistaken for parasites, could be due to this cause. [J. S.]

8.—Konstantinowitsch has made a series of experiments by injecting thick emulsions of lycopodium powder beneath the skin of rabbits. As a result, small tumors formed, which consisted of great masses of polygonal cells, with pale nuclei and numerous giant cells. In a few instances polynuclear cells were found in masses about the blood vessels. The spores of lycopodium are found in the giant cells and in the connective tissue. At the removal of the tumor several weeks after the injection, there was considerable formation of fibrous connective tissue. [J. S.]

9.—The following extraordinary case was observed in the year 1900, by Dr. Lehmann-Nitsche. The subject, a man of 18 years, who has been several times in the hands of the police, and who is at present serving a sentence in prison, was born in Italy and then taken to Argentina. The deformity existed at birth. His parents were peasants normally formed. He was the 3d of 12 children of whom 4 others are alive and healthy, and none of those that died were in any way deformed. The patient has a cleft that involves the frontal bone and the nose, giving rise to an abnormal breadth of the forehead, and a deep depression between the two portions of the nose, causing separation of the eyes. The space between this cleft has probably in the course of time, been filled by bone, which can be plainly felt beneath the skin. Binocular vision is impossible, but the eyes are apparently entirely normal with the exception of a slight impairment of vision on the right side. The nasal septum is on the left side, and the left nasal fossa is larger than the right. There is no separation between the two superior maxillary bones, but a distinct groove can be felt where they are united. The mouth is normal in formation. Two of the incisors are only rudimentary in the upper jaw. Otherwise the patient is normal. His intelligence is only moderate. An operation is not under consideration. [J. S.]

10.—Kobler, discussing the etiology of tropical abscess of the liver, calls attention to the great importance of

dysentery in its causation. In the hospital at Sarajew, he has observed 10 cases of liver abscess in 1397 autopsies. In 8 of these the cause was dysentery, and in 2 suppuration of the biliary vessels. In addition 2 other cases have come to his knowledge, in which the diagnosis of liver abscess was confirmed by operation. In both of these the cause was dysentery. [J. S.]

11.—Henke reports 3 cases of malignant endocarditis; 2 associated with meningitis. In all three the cause was the diplococcus of Fränkel. He concludes that therefore the diplococcus may be the cause of septicemia and pus formation. There are not, however, changes in the heart that are characteristic of the action of this organism. [J. S.]

12.—(1) Schmidt insists that in his experiments published in 1889, he proved that hemosiderin is formed from the blood, and that it gradually loses the micro-chemical reaction of iron. He also thinks that the pigment occurring in tumors is probably derived from hemoglobin. Virchow adds a brief note to this, and states that in 1817 he suggested that the brown pigment in cases of chronic passive congestion of the lungs was derived from hemoglobin. He now believes that it is in part at least, the result of infiltration of coal dust. He calls attention to the fact that many so-called modern discoveries are merely reiterations of things already carefully described in the literature.

(2) Van Walsen, in order to avoid injury to the dura and the brain itself in sawing through the skull, has devised an ingenious instrument which consists essentially of a saw with a guard placed alongside the blade, to prevent its penetrating too deeply into the bone. This guard can be adjusted with the thumb that holds the saw. This is employed first by making a shallow groove all around the skull, and then gradually deepening this, paying particular attention to those regions where the skull is normally thin. The calvarium is then separated with a few blows of the chisel and carefully removed. Occasionally a temporary hemi-craniotomy may be made with advantage. In this case an incision runs parallel to the sagittal suture, then from the frontal bone to the fronto-malar articulation, and from the occipital bone to the external ear. The flap may then be readily fractured by bending it outward. He considers the advantages of his saw are: The rapidity of its operation; its simplicity; the possibility of perfect re-coaptation, and the very slight loss of substance. (3) Beneke replies vigorously to Hansemann. He believes that anaplasia is a physiological process, and he does not find in Hansemann's writing anything that leads him to believe that the latter regards tumor cells as really anaplastic embryonal cells. (4) Löwe suggests that in order to see the cavities of the nose the upper jaw be separated from the maxillary bone, then the cavity of the nose separated from the hard part with the chisel thrown back, and the resulting cavity illuminated by means of the ordinary electric reflector. Further dissection with the chisel exposes the base of the brain. (5) Virchow reports the amount of damage done to his museum. It appears that the fire did not injure the pathological collection, nor the new lecture-room, but did interfere considerably with the laboratory work of the institution, and caused great loss in the anthropological and pre-historical collections. These collections were largely the personal property of Virchow. [J. S.]

WIENER KLINISCHE WOCHENSCHRIFT.

June 29, 1901. (XIV Jahrgang, No. 25).

1. Subcutaneous Injections of Vaseline. LUDWIG MOSZKOWICZ.
2. Objective Disturbances of Sensibility in the Trunk in Aneurysm of the Aorta. H. FRICK.
3. A Case of Infantile Encephalopathy. HUGO LUKACS.

1.—Moszkowicz, who is Gersuny's assistant, reviews the work performed by Gersuny's method of subcutaneous injections of vaselin, (unguentum paraffini), during the two years since the idea originated. The "vaselinum albißimum medicinale" is used, the melting point of which is from 36° to 40°C. After refuting the opposition of a few experimentors, Moszkowicz describes the effect of the injections. Connective tissue soon forms, the vaselin is encapsulated, and hardens. Where the tissue is tightly bound down, Schleich's infiltration anesthesia will prepare for the injection, and only a small quantity of the vaselin should then be injected at a time. When not subjected to pressure, this encapsulated vaselin will remain for years

unchanged, and is not absorbed at all. The case histories of 30 cases treated by this method follow. The injections were used in the scrotum to take the place of a testicle removed; in the urethral mucous membrane for incontinence of urine in a woman; in the posterior wall of the pharynx for improving the speech after an operation for cleft palate; in the mouth and rectum, to close fistulae; in the inguinal canal to prevent the recurrence of herniae; in the vaginal wall for prolapse of the vagina; and for curing deformities in the nose, cheeks, eyes, skin, and chest wall. It was also employed to prevent ankylosis in the knee joint, and to separate nerves which had been severed for neuralgia. The vaselin is sterilized by boiling it, and is then cooled in the syringe. It is injected as a fine thread. The needle need make but one puncture. [M. O.]

2.—Frick reports a case of aneurysm of the aorta in a waiter aged 47, who had had syphilis. Five months ago he noticed pain in his back, so severe that he could not lie down. There was pulsation of the head and larynx, rhythmical, in time with the pulses, which were equal. There was also marked pulsation over the first intercostal space on the left side. A small area of dulness existed to the right of the sternum, but no other signs of an aneurysm. There was pain along the intercostal nerves, on both sides, with marked disturbances of sensibility. Hyperesthesia appeared at first, now hypoesthesia remains. The intercostal neuritis, due to pressure, was the main symptom of the aneurysm for months. Subjective symptoms were entirely absent. A full review of the literature of sensory disturbances with neuritis follows. In this case appearances changed quickly. Schlesinger considers this characteristic of an aneurysm of the aorta. There were no suspicions of hysteria in this case. [M. O.]

3.—Hugo Lukács reports a case which he terms infantile encephalopathy. A man, aged 26, who had two imbeciles in his mother's family, had convulsions when teething. He walked at two, and talked at three years. He was always disobedient and angry. It took him eight years to learn to write and read. Until the age of 13, he had enuresis nocturna. Then followed attacks of vomiting with convulsions and amnesia. He has illusions, optic atrophy, right hemiplegia, and the right radial pulse shows half the pressure of the left. The hemiplegia, moral insanity, and epilepsy all three make up the condition of infantile encephalopathy, most probably due to the cause of the first convulsions when he was teething. This may have been an infectious disease, a traumatism, etc. [M. O.]

CENTRALBLATT FUER INNERE MEDIZIN.

June 1, 1901.

On Artificial Glycocoll Poverty of the Human Organism and the Dependence of the Amount of Glycocoll in the Organism upon the Secretion of Bile.

OTTO ZIMMERMANN.

It is well known that the glycocoll in the organism combines, so far as is necessary, with certain poisonous substances rendering these substances harmless and being itself excreted in combination with the poison. Chief among these poisonous substances is benzoic acid, which unites with glycocoll to form hippuric acid. Zimmermann thought that if it were possible to combine all the glycocoll with benzoic acid we could estimate the amount of glycocoll being formed by determining the amount of hippuric acid in the urine. It is impossible under normal circumstances to give so much benzoic acid as would be necessary for this purpose without causing poisoning, but Zimmermann took advantage of a case of biliary fistula in which practically all or perhaps all of the bile was excreted through the fistula, and administered 5 gr. daily of sidonal which is a quinate of piperazin, whose quinic acid, either entirely or to a greater part becomes changed in the economy to benzoic acid. He found that on the days when the bile was flowing through the fistula, no hippuric acid was found in the urine, but when the fistula was closed and the bile again passed normally into the intestine, hippuric acid appeared in the urine in considerable amounts. During the first period free benzoic acid was found; during the latter period it was not. He decides from this that the liver is the only organ that produces glycocoll and that in this case none was produced. He believes that glycocoll is produced from the bile acids after their reabsorption from the intestines. Hence he also considers that in the case reported no bile

acids were absorbed from the intestines and none reached there since the feces contained none. Therefore he believes that he demonstrated that this was a case of absolutely complete acholia; and he also considers that complete acholia may be satisfactorily demonstrated in this way for either clinical or experimental purposes. [D.L.E.]

LA PRESSE MEDICALE.

June 15, 1901. (No. 48).

1. Is Leprosy Contagious? DOMINIQUE SAUTON.
2. Injuries to the Sinuses of the Dura Mater
GEORGE LUYSS.
3. Puncture of the Sacral Canal by the Epidural Method.
FERNAND CATHELIN.

1.—Sauton, who has done a good deal of work upon leprosy, reviews the subject, concluding that leprosy is contagious, though this is rather rarely noted, because hygiene, cleanliness, asepsis and antisepsis prevent contagion. In spite of this, Sauton has been able to collect 70 cases of leprosy by contagion. [M. O.]

2.—Of the sinuses of the dura, those most often injured are the superior longitudinal sinus (41 cases reported) and the lateral sinus (16 cases reported). The cause of injury may be a fall upon the head, a blow with some force, or trephining. These injuries may occur in child-birth, from compression; in childhood, by disjunction of the bones of the skull; and in adult age, with or without fracture of the skull. If a fracture of the skull occurs, splinters of bone may penetrate the sinus. Without fracture of the skull, the lateral sinus may be injured by forcible extension of its walls. Pathologically the injuries may consist of one or more small or large perforations, tears, or ruptures of the sinus. If a fissure exists, the blood may escape through it. If the hemorrhage remain inside the skull, it may collect outside the dura (extradural) or inside the dura (intradural). In either case, infection may occur. The article is illustrated with drawings to show the injuries of the sinuses. [M. O.]

3.—Cathelin reports the experiments upon animals which led to his puncturing the sacral canal by the epidural method in man, and describes the technique of the operation. He introduces the needle (6 cm. long) just below the fifth sacral vertebra, the point entering obliquely in the median line. Then, when the injection is slowly made, the fluid is well diffused. The advantages of the method are that the injections remain exclusively vertebral; that large injections can be given; that it is easy and causes no pain. Cathelin advises this method for administering cocaine anesthesia, and for the injection of drugs, especially in the treatment of neuralgia. [M. O.]

JOURNAL DE MEDECINE DE BORDEAUX.

June 2, 1901. (31me. Année, No. 22).

1. Primary Tuberculosis of the Spleen. B. AUCHE.
2. Syphilis in the Horse. M. Rouget.

1.—Secondary tuberculosis of the spleen is almost as common as tuberculosis of the lymph-glands. On the other hand, primary splenic tuberculosis is rare. Auché describes the tenth published case. A man of 38, of excellent family and personal history, had always easily caught cold. Eight years ago he first noted pain in the left hypochondrium, supposed to be due to a dilated stomach. Two years ago Professor Demons found an enlarged spleen. The patient entered the hospital three days before death, emaciated, ascitic, and dyspneic. The autopsy showed a huge spleen, weighing 1250 g., hard, granular, and caseous. Liver and kidneys were also enlarged. The peritoneum, pleura, and pericardium showed white granulations. No tubercle bacilli were found in the spleen, but rabbits inoculated died, showing tubercle bacilli. But one case of the 10 reported was acute; the rest were all chronic. The lymph-glands of the hilum of the spleen, mesentery, mediastinum, peritoneum, pleura, and diaphragm were tuberculous. The liver showed sclerosis and tubercles. The peritoneum was only affected at the end of the illness. The point of entrance of the bacilli is unknown. Auché believes this case to have been of the spleno-hepato-peritoneal type. [M. O.]

2.—Very similar to syphilis in man is "dourine," the syphilis of the horse. History shows that the disease in

the horse was probably acquired originally from man. In the horse its course is always chronic. It is now found principally in Algeria. About 20 days after colitis the genitalia show a chancre, and enlarged inguinal glands. Later the eruptions appear. This eruption was the origin of the name of "dourine," as it resembled the old coin, "douro." Finally comes paralysis of the posterior horns. In mares the disease occasionally runs an acute course, causing death in three days. Nocart, after long experimentation, found a parasite in the blood, which, when inoculated into white mice, caused the disease, showing the parasite after death. The parasites were flagellated protozoa. Besides, inoculated rabbits caused the disease in other rabbits by sexual intercourse. Rouget suggests that such a parasite may be the cause of syphilis in man. Yet while all the animals take "dourine," hardly any will take syphilis. Not only has mercury no therapeutic action upon "dourine," but it even seems to act deleteriously. [M. O.]

JOURNAL DES PRATICIENS.

June 8, 1901. (15me. Année, No. 23).

1. Neuralgia With Latent Aneurysm of the Aorta.
HENRY HUCHARD.
2. Delirium In Senile Gangrene. PAUL FABRE.

1.—Huchard reviews the case of a man of 50, who came to him complaining of neurasthenia, frequent palpitation and left-sided intercostal neuralgia, for years. Nothing had done any good. He leaned over all the time. When forced to stand up straight, characteristic expansile pulsations were felt at the base of the axillary region, with almost syncope. To sleep, he had to lie upon his abdomen. Huchard diagnosed an aneurysm, which was confirmed by radioscopy. Neuralgia is one of the main symptoms of latent aneurysm of the descending thoracic aorta. Abdominal aneurysms also will cause neuralgic pain. Huchard reports the case of a man of 46, with pain about the left shoulder occurring in paroxysms. There were signs of aortic insufficiency, but the sphygmographic tracings were normal. Radioscopy showed an aneurysm of the descending aorta. Rest with potassium iodide, 450 grains daily, and 120 grains of calcium glycerophosphate, caused diminution of the pain and of the aneurysm. Neuralgia is the only outspoken symptom of latent aneurysm. It will remain in one spot, and be increased or decreased by changes of position. The diagnosis is settled by Röntgen photographs. This is not new, as Morgagni discovered it, but, as Huchard says, it will bear repetition. [M. O.]

2.—Fabre describes two cases of senile gangrene with delirium. The first case was in a man of 77, with gangrene of the little toe of the right foot. Lypemania and hypochondriacal delirium occurred. He was continually wishing to die. He recovered. The second case was a man of 68, with gangrene of the fourth and fifth toes of the left foot. He had acute delirium with hallucinations, singing aloud. In neither case had alcohol been used; and both cases lasted about three weeks. Other cases of delirium in senile gangrene are quoted. Fabre believes that the cause varies; it may be due to arterio-sclerosis, septicemia, or nervous exhaustion from the pain. [M. O.]

Hemoglobiuria in Malaria.—In discussing hemoglobiuria in malaria, in (*La Presse Médicale*, 1901, No. 41), Troussaint describes four conditions which favor exodus of the hemoglobin from the erythrocytes, and its solution in the blood serum. These conditions are (1) the presence in the blood serum of two categories of hemolytic substances, those which demineralize the plasma like bile, urea, etc., and those which act like ammonium chloride; (2) globulolysis by the normal hemolytic serum and (3) by the serum acquired by vaccination; and (4) direct mechanical globular effraction due to the penetration of the hematozoa into the erythrocytes. After a long discussion of the subject, Troussaint concludes that the relation between malaria and hemoglobiuria is that of cause and effect; that hemoglobiuria results from demineralization of the blood due to alterations in the liver from the malaria; and that its treatment should be small doses of quinine, enough to destroy the plasmodium, with subcutaneous injections of sodium chloride solution, which will oppose globulolysis by favoring the elimination of urea, bile, etc., and by increasing the isotonic power of the blood serum. [M. O.]

British Congress On Tuberculosis

(Continued from Page 263).

On the Transformation of Tuberculous Soil Deficient in Acidity into an Arthritic Soil with Excess of Acid.—By Dr. Samuel Bernheim, Paris. The author commences by studying the character of the tuberculous soil, the biochemical condition of which should be well known to everyone at the present day. The measure of the mineral richness and of the chemical condition of the organism may in some degree be the measure of its resistance. But we know, that the tuberculous patient possesses a soil deficient in mineral constituents, wanting in chlorides, lacking phosphates, and above all deficient in acids, whilst the arthritic patient has a soil that is over-mineralized, exceedingly rich in chlorides and superabundant in acidity. That is to say, in chemical language, these two soils are in inverse proportion to one another. Similarly, from a clinical point of view, there exists a kind of antagonism between tuberculosis and the arthritic diathesis. Phthisis is rare among arthritics and of benign manifestation in them. From these first data—chemical, biological and clinical—the author draws numerous therapeutic deductions. It is thus, according to him, that the system of sanatoria, the absolute rest, the abundant feeding, the high-altitude cure, have no other end and no effects than the transformation of the soil. All these beneficent factors which have less effect on the bacillus than on the general system, tend to increase the organic acidity of the patient. And, in fact, the author has submitted a certain number of patients to complete repose, and he has proved in their case, at the end of a certain period, the existence of a very evident increase in urinary acidity. Similarly, the meat cure, so highly recommended by MM. Richet and Héricourt, does not act by means of antitoxins, but by a transformation of soil, the acidity of which they enrich.

After thus giving an interpretation of facts M. Bernheim adds that it is possible to obtain this transformation of soil, especially in the case of tuberculous patients who are treated early, by a hygienic and dietic regimen, and by saturating the general system with a powerful acid such as phosphate of creosote or phosphoric acid. At the Anti-Tubercular Dispensaries of Paris he has observed a large number of patients in whom he has frequently estimated the urinary acidity. Now he has proved that under the influence of phosphate of creosote, taken in doses of three grammes every two days, the acidity rapidly increases and the general condition improves; whence we are right in concluding that it is possible, by artificial methods, to transform a soil deficient in acid and favorable to tuberculous evolution into a hyper-acid soil, and one that is antagonistic to Koch's bacillus. This transformation, which is, according to the author, the sheet-anchor of the subject of phthisis, should be sought by means of, and perhaps obtained by, a hygienic and dietetic regimen, as well as by powerful therapeutic measures.

Tuberculosis of the Eye. By Dr. Allen T. Haigh, Chicago. The paper begins with the history of Tuberculosis in the various parts of the eye; treats of ocular disease as possibly the only and earliest manifestation of tubercular affection; gives the ages in which the local disease may occur, and quotes numerous authorities and conclusions; tabulates the number of published cases; gives the countries in which they occur; report of cases; treats of hereditary and primary Tuberculosis of the eye, and concludes that ocular tuberculosis is due to two causes; urges early enucleation of the affected organ, with the belief that such procedure saves many lives.

Treatment of Anorexia in the Tuberculous by Persodine (Persulphate of Soda). By Dr. J. Hobbs, Bordeaux. We all know that the condition of a tuberculous patient is measured by that of his stomach. The subject of tuberculosis who can take nourishment is in a good condition to struggle against the bacillus, and to hope for cure; unfortunately, it frequently happens that from the time of the first symptoms, and even when the pulmonary symptoms are little advanced, there is an absolute anorexia. In spite

of the advice of his physician, who orders him abundant feeding, the tuberculous patient makes every effort, and does not succeed, in eating. It is in vain that one bitter after another is tried; they all fail, emaciation proceeds apace, and cachexia little by little is established. Many drugs besides bitters have been tried with a view to combating the anorexia, and quite lately chemistry has supplied us with a new product destined to restore the function of nutrition in the tuberculous, and call oxidation into activity. This product is persulphate of soda, the first preparation of which under the name of persodine is due to MM. A. and L. Lémère, of Lyons.

These workers have at the same time produced mineral persulphates of potassium, sodium, ammonium, barium, and lead, and some organic persulphates, the chief of which are the persulphates of cocaine and quinine. These very instable salts have been studied from different points of view by MM. J. Nicolai, Garel, Rigot (of Lyons).

In this study we shall confine ourselves solely to the part they play in nutrition, and we shall direct our attention to one salt alone, persodine (persulphate of soda). Leaving also on one side those cases in which we have prescribed this drug for chorea, anemia, neurasthenia, etc., we shall concentrate our attention on one particular instance: anorexia in the tuberculous treated by persodine.

The cases we have observed are six in number. Summing them up very briefly we class them in the following manner: A case of doubtful pulmonary tuberculosis in a girl of twelve years—doubtful in the sense of our not finding bacilli in the sputa, in spite of positive stethoscopic signs. Three cases of pulmonary tuberculosis in the first stage in two children of five and eight respectively, and in an adult male of twenty-four years, the latter with fever. Tuberculosis in the second stage in an adult male of forty-nine, also the subject of fever. Tuberculosis in the third stage in a male adult of twenty-eight, with great increase of temperature.

These six patients were troubled with an anorexia more or less severe, the children principally suffering. We have given persodine to all of them an hour before meals, in a little water—a teaspoonful at a time for children; for adults, a tablespoonful.

From the second day, in the case of the child attacked with doubtful tuberculosis, and in the case of one of those that had reached the first stage, the appetite returned; and from the fourth day it was regained in the cases of the other patients.

In all of them it was shown by a sensation of emptiness at a level with the pit of the stomach, together with a real craving for nourishment. On the fifth day the parents of one of our little patients told us that the child ate greedily.

All our patients increased in weight: the little girl attacked with doubtful tuberculosis gained 4 kilogrammes in twenty days! the other two from 3 to 3½ lbs. Two of our adult patients noticed their weight increase by 60 to 62, and by 70 to 71.500 kilogrammes respectively in twenty-five days.

Even our patient in the third stage derived some benefit from it. The emaciation, which had been progressive, was arrested; there was an increase in weight of 500 grammes, which unhappily at that point went no farther. To sum up we may say that all our patients have increased in weight from the use of persulphate of soda.

In the case of one patient we were able to make a full analysis of urine, dephosphatization was arrested.

In spite of the rather large doses—two tablespoonsful a day—none of our patients suffered from diarrhea.

We conclude, therefore, that persulphate of soda stimulates nutrition, and that it is effectual in combating anorexia in tuberculous patients.

Devitalized Air Toxemia a Prime Cause of Tuberculosis. By Charles Denison, Denver, Col. Under this head it is intended to discuss the degenerative effects of deficient ventilation, and to show how, through the devitalization of the air, by its loss of vitality, due probably to a change in its normal electrical state, a dyscrasia (in persons breathing it) is created, which gradually drifts into degeneration of tissue, the so-called "soil" of tuberculosis.

The Richardson experiment is discussed, and the need is emphasized of further experimentation on this line in order to throw more light upon this important matter. The prevailing idea among medical men that the tuberculosis germ is the only cause to the exclusion of as important

predisposing causes, is criticised. The question of "soil" is now even more important than that of "seed," in order to successfully combat this dyscrasic disease.

Man, under our present civilization, is very generally tainted with a dyscrasia which goes back to this devitalized air toxemia for its cause. The fault is the disproportion of breathing-space and sun influence to the needs of man in sleeping, living, and working rooms.

The *deficient ventilation cure*, upon which the most civilized peoples are living will, by illustration, be contrasted with the *normal life cure*, which should represent the longer and uncontaminated lives of a people living under natural conditions.

Out door life is thus suggested as the *key note* to this congress.

The need of education along these lines will be emphasized and plans for legislative control, through yet to be enacted laws, will be suggested.

I. Tuberculosis in Bovine Animals: Its Dangers, Its Progress, its Prophylaxis. By Ed. M. Nocard, Alfort. *Conclusions:* A.—Tuberculosis is one of the diseases of cattle which causes most loss to agriculture in all countries.

B.—Everywhere the disease is on the increase; everywhere it forms a menacing danger to public health as well as to public wealth.

C.—Infection being the only formidable cause of the increase of tuberculosis, there is need for the adoption of legal measures prescribing:—

1. The complete separation of unhealthy from healthy animals.
2. The slaughtering without delay, of those sick animals which show clinical signs of the disease, and especially of cows attacked with tuberculous mastitis;
3. The interdiction from selling other tuberculous animals for a destination other than the slaughter-house.
4. The pasteurization of all the sub-products of butter and cheese manufactories.

II. On the Risks Involved to Man From Tuberculous animals (co-occupation, Meat, Milk), Means of Guarding Against Them. *Conclusions:* A.—The resemblance of tuberculosis in man and in mammals is no longer denied. Healthy cattle-sheds have been infected by lengthened occupation by consumptive cattle-men.

The converse is equally possible, at least theoretically. If it is not thought possible to prohibit cattle-men from sleeping in cattle houses containing tuberculous cows, the least that can be done is to warn the proprietors of the risks of this practice, and of the responsibility they may eventually incur. The nightly supervision of the suspected cowshed can be effected by means of a glass building looking on to the cattle-sheds, but having no direct communication with them.

B.—Meat obtained from tuberculous animals is rarely dangerous, and when it is dangerous it is only slightly so. The established regulations for the inspection of tuberculous meat would be sufficient to prevent even the shadow of danger, if such regulations were applied always and everywhere.

Unfortunately this is not the case.

The inspection of meat is organized only in a small number of large towns; it ought to be done everywhere, in villages as well as in towns, and it should be everywhere forbidden to sell meat not bearing the stamp showing that it has been declared to be wholesome by a competent inspector. This inspection could be easily carried out, and at little cost, on a similar plan to that adopted in Belgium for many years.

C.—The milk given by tuberculous cows is rarely dangerous, but when it is dangerous it is most often so in a very high degree; hence the necessity of submitting cow-houses to a periodical inspection when the milk yielded is destined for public consumption. Cows being really only dangerous when they have a tuberculous udder, the inspector's attention should be drawn to the state of the udder. Any cow showing clinical signs causing suspicion of the existence of a tuberculous mastitis, or of serious visceral tuberculosis ought to be isolated at once, pending the making of a diagnosis, this being easily and rapidly done by the present process; the milk should be boiled before being sold and consumed, even by the animals on the farm.

The dairyman should be obliged to give information to the inspector as soon as he has ascertained the appearance of a mastitis of any sort. When the diagnosis is confirmed, the diseased cow should be rigorously excluded from giving milk, and should be slaughtered without the least possible delay. Lastly, the sub-products of butter or cheese manufactories (skimmed milk, butter-milk whey, etc.) should not be delivered for the consumption of persons or animal until they have been pasteurized at the minimum temperature of 85 centigrade.

III. Presentation of a goat attacked with experimental mastitis, and demonstration of diagnosis called "harponnage."

IV. Presentation of tables demonstrating the efficacy of the procedure recommended by the author for rendering cow houses, that are most seriously infected with tuberculosis, healthy and to restore them to their original state without being obliged to buy a single animal from outside. Calves born of tuberculous cows remain healthy on the only condition of isolating them from their mothers as soon as they are born and of feeding them by bottle with boiled milk.

On the Relation of the Tubercle Bacillus to the "Acid-Fast" Bacteria and to Actinomyces. By Dr. Moeller, Belgig. The discovery in recent years of "acid-fast" bacteria, other than that of tuberculosis, has rendered the diagnosis of the tubercle bacillus by the microscope alone impossible. There has been a considerable amount of discussion as to the cause of this "acid-fast" property. Klein and Marmoreck have recently shown that quite young tubercle bacilli do not exhibit it, probably from the absence of the waxy and fatty envelope present in the full-grown bacillus. Borrel, by the prolonged action of warm xylol, has removed this waxy envelope, and the bacilli are then found to be no longer "acid-fast," though still capable of producing tuberculosis. Bacilli which closely resemble that of tuberculosis, and which have been known for some years, are the bacillus of leprosy, the smegma bacillus, and the bacillus of avian tuberculosis.

The characters of these and the points in which they differ from the bacillus of tuberculosis are briefly described. The writer then passes on to consider a series of organisms whose presence in our environment has been recently demonstrated, and which closely resemble the tubercle bacillus. Some of these, such as the Petri-Rabinowitsch and the Korn bacillus, occur in butter and in milk. The butter bacillus is not so resistant to acids as that of tubercle, and though when injected into guinea pigs along with butter appearances closely resembling those of tuberculosis are produced, yet an indurative peritonitis usually results as well. As the milk bacilli present such a close resemblance to the grass bacilli that the author considers we are justified in regarding them as modifications of the latter. The grass bacilli (Timothy bacillus and grass bacillus II.) resemble in staining reactions and morphology the tubercle bacillus but grow more slowly, and the temperature relations are different. Like all acid-fast bacilli they produce on inoculation a pseudo-tuberculosis; they do not, however, appear to play any part in the etiology of genuine tuberculosis, and we still know the tubercle bacillus as a *saprophyte* only in artificial cultures. Babes has recently described actinomycotic formations after the subdural inoculation of tubercle bacilli in rabbits, and others have got similar results by other methods. It would appear, however, that the tubercle-actinomyces differs from actinomyces-bovis, in that the direct relation of a bacillus to a club formation can only rarely be shown. Lubarsch has shown that other acid-fast organisms can also produce actinomycotic formations. Although the tubercle bacillus is thus shown to be one of the highly-organized myces, it has not as yet been kept constant in that form. Perhaps in course of time the necessary conditions will be discovered. In the meantime the tubercle bacillus is of most importance in the stage in which we know it best, *i. e.*, as a parasite in the form of little rods.

Discussion of the Role of Dispensaries in the Prevention of Tuberculosis. By Dr. Samuel Bernheim, Paris. After having recognized the salutary action of sanatoria, the author declares that the dispensaries recently founded in Belgium and France are also called upon to operate in the struggle against the Koch bacillus. These dispensaries are, so to speak, branches of the large sister hospitals, and are for the reception and care of poor people. These pa-

tients, who crowded (at once) in large numbers to the dispensaries in Paris, are minutely examined in order to discover the earliest possible symptoms of tuberculosis. They are not only provided gratuitously with medicine, food and clothing, and even money, but they are warned to be on their guard against contagion. They are taught to take all precautionary measures in the schools, workshops, and in their homes. A certain number of sanitary officials attached to this philanthropic undertaking for preservation of life look after the patient at his own home, and keep a strict watch over him to ensure that existing rules are observed. Any patient who disobeys these hygienic rules is immediately deprived of the advantages afforded by these dispensaries. In addition, every month the Society of Philanthropic Dispensaries gives a popular lecture to warn the public of the dangers of tuberculosis and the forms of it likely to attack them in their various walks of life. Phthisical patients are so numerous in most countries that nations which have established large numbers of sanatoria cannot provide classified and separate accommodation for patients. Consumptives treated by these dispensaries, especially those in the early stages of the disease, can derive the very greatest benefit from them. From a prophylactic point of view they will be found more efficacious even than sanatoria.

On the Function of the Anti-Tubercular Dispensaries in France and on the General Work of Anti-Tubercular Dispensaries. By Dr. Robert Bonnet Léon, of Paris. Tuberculosis causes terrible ravages in France. More than 150,000 persons annually fall victims to this scourge and the numbers are always on the increase. The whole medical world is agreed that tuberculosis is contagious and avoidable; also that it is curable, especially in the early stages. It is considered that a simple and inexpensive method of action should be adopted by which the laboring classes, who are always, owing to their wretched homes, the most exposed to the disease, should be gratuitously provided with:—

1. Education in methods for the prevention of tuberculosis to enable them to avoid infection.
2. Medical advice, nursing and treatment in as early a stage as possible, to cure them.
3. Necessary assistance, especially in the providing of proper food.

Sanatoria are exceedingly costly, they can only deal with an insignificant portion of the population, they do not provide any general education on the subject, and their construction occupies a period of several years. In January, 1900, Dr. Bonnet Léon, one of the first men in France to do so, founded an establishment, which appeared to fulfil all the desired conditions. He called it an anti-tubercular dispensary, and published an account of its methods of working. The results attained there were so conclusive that they led, several months later, to the founding of "The General Association of Anti-Tubercular Dispensaries for the Prevention and Cure of Pulmonary Tuberculosis."

The Government Commission on Tuberculosis in its report, published in January, 1901, expressed its approval of the new dispensary scheme laid before it by Dr. Calmette, of Lille.

At this date Dr. Bonnet's dispensary, which had just been set up in the Rue St. Lazare, was transferred to Montmartre, a very populous and infected area. It consists merely of a small suite of five rooms on the ground floor, very simply furnished, with some medical apparatus such as a microscope, a machine for weighing the patients, Röntgen Ray apparatus, appliances for inhalation and respiratory exercises. Glazed walls, parquet floors and tiles which are easily washed, and the whole lighted by electric light. Registers are kept of admissions, diagnoses, enquiries, assistance given, etc. Medical aid is given after the closing of the workshops by two doctors, two assistants, and an attendant. A large number of patients come, *the majority in early stages of the disease*. This last result, which is *exceedingly important in the cure of tuberculosis*, appears to be due to the title "*Anti-tubercular Dispensary*," which indicates its special aim without frightening the public, to the situation of the dispensary, the easy access that can be had to it, and above all to the patronage of the General Committee, of which Professor Brouardel is President. At the same time people living in

the neighborhood are treated in their own homes, and, while following their ordinary occupations, they are given advice in matters of hygiene against tuberculosis and alcoholism. Thorough inspections of insanitary dwellings are also made. The average of a year's work at the dispensary gives the following statistics:—4000 to 5000 examinations, consultations and special instructions, 400 to 500 courses of three months' treatment (meat, muscle juice, milk, rest and open-air cure in the establishment). In this way conditions similar to those of a sanatorium are obtained for one class of patients, and a practical and real prophylaxis is arrived at. The expenditure of the dispensary amounts to 30,000 francs a year (8000 francs for maintenance and service, 22,000 francs for board of 120 patients for three months, 30 at a time; cost estimated at two francs per head per day). The expenses of the starting of the establishment amounted to barely 5000 francs. The sanatorium, containing 100 beds, and treating 400 patients in periods of three months, costs 300,000 francs to build, and nearly 300,000 francs yearly to keep up on eight francs a bed per day. One can thus see the immense difference in the sums spent and the services rendered. In France there are one hundred thousand workmen who die of tuberculosis every year, or owing to this disease are prevented from working. This represents a loss of two hundred millions to the country.

1. To treat these 100,000 cases of tuberculosis in sanatoria 250 of these establishments would have to be erected in many years' time at a cost of 200,000 frs. $\times 250 = 75$ millions. Each year the maintenance of them would also cost 300,000 frs. $\times 250 = 75$ millions.

2. If the dispensary system were adopted the cost of founding 250 would be: $5000 \times 250 = 1,250,000$ frs. Cost of working $30,000 \times 250 = 7,500,000$ frs. For a million and a quarter on the one hand and seven millions and a-half on the other hand the dispensaries would give every year:—

- (1) Consultations and advice on the prevention of tuberculosis to *more than one million people*.
- (2) Nursing and treatment for three consecutive months to *a hundred thousand patients*.
- (3) Rest, extra nourishment, and special treatment for the prevention of tuberculosis, to *more than three million out-patients*.

This comparison between dispensaries and sanatoria does not imply that the sanatoria should in consequence be abandoned, the latter should to some extent supplement the former by receiving patients chosen and sent by them. I may add that a dispensary in a crowded quarter attracts public attention to the question of tuberculosis, and by nursing patients at their own houses avoids the necessity of scattering them all over the country where they are sources of great danger to others.

The results of the dispensary at Montmartre are very satisfactory from a prophylactic and curative point of view. *A great number of similar dispensaries should be founded by districts or by the State.*

Their establishment would not fail to ameliorate the social conditions of the country. Already the Association of Dispensaries for the Prevention of Tuberculosis has led to the establishment of several dispensaries in Paris and the provinces. The future of France and that of other great nations, who are absolutely defenceless against tuberculosis is dependent upon the success of these dispensaries for the prevention of tuberculosis.

Para-Tuberculous Hereditary Dystrophy. By Dr. E. Mosny, Paris. Clinical study and experimental medicine demonstrate the fact that subjects of phthisis do not transmit the bacillus of tuberculosis to their offspring (*typical conceptional heredity*), and that the very rare cases of *congenital tuberculosis* are due to intra-uterine contamination of the fetus by the tuberculous mother.

Clinical observation, moreover, goes to prove that subjects of phthisis do not transmit to their offspring either a specific predisposition to bacillary contamination or any marked degree of immunity (*atypical specific heredity*). But we should not, however, conclude from this that tuberculosis of parents exercises no influence on the health of their offspring.

Both clinical and experimental medicine, indeed, agree in demonstrating that the tuberculosis of parents has an influence on fecundity and the products of conception similar to that which is exercised by the majority of chronic intoxications such as alcoholism, saturnism, or the infections the evolution of which is slow or prolonged, e.g.

syphilis (*underevent atypical heredity*). These consequences, early or late of the tuberculosis of parents on their future descendants, may be conveniently grouped under the title *para-tuberculous hereditary dystrophy*.

Their frequency is a witness to the grave evil of tuberculosis from a social point of view, which compromises not only the existence of the individual it attacks, but also involves the future, affecting posterity with an irrevocable and permanent taint.

Tuberculosis may even influence conception by producing sterility in the subjects attacked. It may also exercise on the product of conception, from the time of its origin or during the course of pregnancy, either a general influence or one localized more precisely in one of the organs of the embryo or fetus.

Generalized manifestations of hereditary dystrophy appear at all stages of its existence; from conception, or during the course of pregnancy, they are shown by sterility, death of the fetus, abortion, premature birth; when pregnancy arrives at its normal limit, by still-birth, weakness of the off-spring, which is reared badly, pines away, and dies prematurely without adequate cause, or, indeed, survives in a piteous condition, badly or incompletely developed (infantilism, juvenilism, dwarfism), a fit subject for all forms of decay, and exposed without defence to all kinds of contamination. At other times the influence of the tuberculosis of parents on the health of their offspring localizes itself, or shows under multiple forms of most varied manifestation, the consequences of arrest or perversion of normal development.

Among these localized manifestations of para-tuberculous dystrophy the following appear with a frequency that is very marked: hypoplasias of the vessels and blood, pure mitral stenosis, stenosis of the pulmonary artery, generalized stenosis of the arteries (arterial aplasia), and chlorosis.

Generalized or localized manifestations of para-tuberculous hereditary dystrophy and the functional troubles which sometimes depend on them, become apparent, either at birth or not till later on at one of the important stages of growth, *e.g.* weaning, dentition, puberty. Tuberculosis of the father or that of the mother, above all, the latter, is the determining course of these dystrophic congenital defects. Tuberculosis of the parents no more predisposes the offspring to bacillary contamination than it confers immunity against attack. But the offspring of phthisical subjects, organically and functionally imperfect, weak from the time of birth, and more tried than others by the vicissitudes of growth—seem to be pre-disposed to bacillary infection, because the risks of contagion are multiplied infinitely by contact, immediate and continuous, with contaminated parents, and because their weakened frame offers less resistance to the infection so produced. The apparent immunity of some descendants of tubercular subjects who carry with them certain manifestations of para-tuberculous hereditary dystrophy, is, in reality, the consequence of the very nature of the dystrophic lesion or of its localization, and not the manifestation of a real condition of resistance. Such is the *relative immunity* in regard to tuberculosis exhibited by the subjects of chlorosis or pure mitral stenosis.

The Changes requisite in Existing Legislative Measures and Administration for Improving the Condition of Cowsheds and Ensuring the Health and Cleanliness of Milch Cows. By Charles Porter, M. D., Irel., D. P. H. Camb. Almost incredible that under existing general law no sanitary authority possesses any legal right whatever, in regard to *tuberculosis*, to inspect any cows or cowsheds *even in its own district*, nor to make regulations under the Dairies, etc., Order for their inspection, nor to prohibit use of un-boiled tubercular milk for food of animals.

County Councils have no powers whatever in regard to dairies, cowsheds or tubercular animals. The Model Regulations of Local Government Board do not mention cubic space requirements for county cowsheds, though such structures are often specially bad; neither is there any requirement for sufficiency of air-space about heads of cows in cowsheds. The Tuberculosis Clauses of 1899 fail to prevent removal or sale of suspected animals. Hence compulsory slaughter of reacting animals necessary, with partial compensation except when tuberculosis is generalized. Gradual replacement of unhealthy by healthy herds is made possible by tuberculin testing under Bang's condi-

tions. Feeding of calves of tuberculous cows with boiled milk very important. Fraudulent use of tuberculin for fortifying against subsequent tests should be penalized (Young.) Sanitary officers acting *bona fide* should be protected against personal liability.

Legislation necessary. (1) To endow sanitary authorities and county councils with full rights to inspection of all sources of their milk supplies. (2) To amend dairies, etc., orders as above indicated. (3) To provide for gratuitous testing of herds with tuberculin. (4) To apply to country generally the Tuberculosis Clauses of 1899 *plus* powers to prohibit removal of suspected animals and of applying the tuberculin test. (5) For compulsory slaughter of all reacting milchcows, with partial compensation unless disease generalized. (6) For penalizing fraudulent fortifying. (7) For protection of health and veterinary officers from personal liability.

Administrative changes as above implied, and in addition:—(1) Some cubic space requirements for country cowsheds. (2) Periodic veterinary inspection of milch cows. (3) Dissemination of information *re* bovine tuberculosis, and especially *re* tuberculin test and *re* importance of wholesome milk for calves.

Destruction of Tuberculous Sputa. By Prof. Schrötter, Vienna. The best method of getting rid of this kind of sputum is, in my opinion, destroying it completely—by burning.

The sputum of patients walking about is collected in Dettweiler's bottle, somewhat modified by me; that of those lying in bed in my papier-maché spittoons, containing a little powdered turf. Then the contents of the bottles and the spittoons themselves, all well mixed with turf, are thrown into the fire.

Remarks on Tuberculosis and the Milk Supply. By John A. W. Dollar. The relations of bovine and human tuberculosis and their intercommunicability. Transmission of bovine tuberculosis to man; necessity for a certain concentration of the bacilli in transmission by the digestive tract. Reservations in regard to accepting results of inoculation and feeding experiments in rodents as applicable to man. Intestinal tuberculosis in children; rarity of primary tuberculosis of the bowel in children and in men; possible reasons for this. Bovine tuberculosis in Europe; proportion of tuberculous cows as shown respectively by slaughter house statistics and by tuberculin test; proportion of cows with tuberculosis of udder. Tuberculosis common to goats, asses and sheep, as well as to cows. Detection of tubercle bacilli in milk as sold.

Methods of preventing spread of tuberculosis by milk. Sterilization and pasteurization of milk, their advantages and drawbacks. Examples of commercial establishments supplying pasteurized milk. Sterilization of milk on a commercial scale. The eradication of tuberculosis from herds of milch cows. Examples of commercial establishments supplying milk from guaranteed tubercle-free herds; their success. Improved hygienic treatment of milch cows; Bang's system of stamping out tuberculosis. Experiments on Bang's system in Belgium, Canada, and the U. S. A. Tuberculosis in New Zealand. Legislation in regard to milk traffic proposed by German Milk Trade Union.

Tuberculosis and the Milk Supply. By James Lalthwood, F.R.C.V.S. This subject very forcibly brings to my mind the words of Sir William Broadbent when he said, "Already the number of deaths from consumption and other forms of Tuberculosis have been reduced by more than fifty per cent. in fifty years. The single sad exception to this statement is that *Tubercle mesenterica*, the disease of the bowels in children traceable to tubercle conveyed by milk, has increased." This was told to the country in 1898.

Royal Commissions have been appointed one after another, and told our legislators years ago in no uncertain voice the great danger of tuberculous milk especially to infants.

The intelligent law-makers in other countries continue to make regulations to control this dreaded disease, while the responsible authorities in this country do nothing but stand by and watch the pitiable and lingering yearly deaths of 70,000 of its population. Surely it is not British to shrink from this foe which is admittedly the most deadly enemy of our race. A great war is nothing to it, as this claims its number of victims every year.

How, then, can we best prevent it? So far as the milk supply is concerned, it is a most simple and easy matter.

1. The first thing is the establishment of a State Veterinary Service, to exercise functions co-ordinate with those of the Medical Officer of Health for each city, borough, or county, whose duty it will be to supervise the health and sanitary condition of all animals within their jurisdiction, and to carry out the regulations of the Contagious Diseases (Animals) Act.

Italy has set a very commendable example in this respect.

II. Include the disease in the Contagious Diseases (Animals) Act.

III. The detection of the disease. This can only be well done by the aid of tuberculin, and no other than a qualified veterinary surgeon should be permitted to use it on animals.

And now comes the question, Who is to pay him—the farmer, the retailer, the public, or the Government? Most other countries have decided on the latter, which really means the public indirectly; and as it is the public who are benefitted by it, they ought to pay for it.

IV. It should be made unlawful to sell, offer, or expose for sale milk with any representation of purity unless the seller can produce a certificate from a qualified veterinary surgeon that the animals which produced it have passed within six (or twelve) months the tuberculin test. (This is very necessary, as at this present time scores of milk retailers are selling what they represent to be non-tuberculous, which is from cows that have never been tested.)

V. Sterilization of all imported milk at the port of landing at the cost of the importer.

VI. Compulsory notification of all diseased udders.

VII. All cow-houses and cattle producing milk for human consumption should be under uniform official veterinary supervision, especially as to air space, ventilation, light, drainage, and water supply.

A very serious error appears prevalent in many quarters, viz., that the milk of a cow having no appearance of a diseased udder is perfectly safe for human consumption; but my experience teaches me that such is not the case.

In some experiments I was permitted to carry out for the County Council of Cheshire, Professor Delépine found numerous tuberculous bacilli in the milk of one cow that reacted to tuberculin, whose udder was perfect, so far as manual manipulation was concerned.

Under the above-mentioned grave mistake this animal would be allowed to remain to sow the seed of destruction.

The same has been proved by Nocard, Bang, May and Bollinger.

A most commendable example is being set by the "Manchester Pure Milk Supply Co.," who distribute milk from 500 cows, all of which are tested with tuberculin every six months, all reactors and doubtfuls being removed from the herd; and each homestead is visited by a veterinary surgeon once a month, who reports to the company the condition of cleanliness of cattle and cow-houses, the suitability of food consumed, and water supply, ventilation, drainage, etc.

This is the condition that should be attained by all, and if the above recommendations could be made compulsory, or even No. IV. alone enforced, all danger from tuberculous milk would be removed.

Remarks on Question on Control of Milk Supplies. By Dr. Malm, Christiania. 1. The tuberculin employed for diagnosis should be a tuberculin produced on the same principles as that of Koch in 1890.

Its strength should be uniform, and it should be of such toxical strength as to kill with certainty six to eight weeks' old tuberculous guinea-pigs within eight hours in doses of 20-30 centigrammes subcutaneously.

2. Such a tuberculin produces unfailingly in tuberculous animals a febrile reaction of a distinct type. It is recommended that large doses should be given, even to young animals; there is no danger or inconvenience in always employing doses of a half to one gramme.

3. Tuberculin may at times also produce fever in non-tuberculous animals, but this fever is not typical and does not attain such a degree as in tuberculous cases.

4. If a typical tuberculous reaction appears in an apparently healthy animal, and, on dissection, nothing tuberculous is found, it is the fault of the dissector.

5. To determine with certainty whether reaction exists or not, it is necessary to take the temperature from the 6th to the 20th hour after injecting, hourly or at least every second hour.

6. The fact that tuberculin in a few isolated instances produces fever in non-tuberculous animals, is of no importance when the question is its usefulness as a means to eradicate tuberculosis, for in this respect it is decisive, as tuberculin invariably causes reaction in tuberculous animals.

7. The foregoing refers to animals treated for the first time. Most animals become more or less accustomed to the tuberculin, but this is uncertain and unreliable and can be overcome by the use of an increased dose or a tuberculin of greater toxical strength.

8. The practical combating of tuberculosis concerns administrative, economical and social spheres, and the answer must vary in different countries according to the prevalence of the disease and its extent, the system of farming and cattle-trade, and the pecuniary means available.

JOURNAL DE CHIRURGIE.

May-June, 1901. (Première Année, No. 5).

1. Congenital Luxation of the Hip Treated by Schede's Method. HENDRIX.
2. The Treatment of Fracture of the Patella. LEBESGUE.
3. Chloride of Ethyl as a General Anesthetic. VERNEUIL.
4. Operative Depletion of the Portal Circulation. CHARLES WILLEMS.

1.—Hendrix reports two cases of congenital luxation of the hip treated by the Schede method. This method consists of rotation of the hip internally, not externally as in the Lorenz method, until the foot is at a right angle to the body, when a subcondyloid osteotomy is performed, after first solidly fixing the hip-joint with a steel nail which passes through the trochanter, neck, and head of the femur, and the acetabulum. In both cases the results, anatomically as well as functionally, were excellent. The Schede method is therefore superior to the Lorenz bloodless operation. Five radiographs accompany the article to show the position of the head of the femur in the different stages of the proceeding. [M. O.]

2.—Lebesgue reports five cases of fracture of the patella, which were treated with pads above and below the fragments, a long zinc rod behind the leg, and an extension apparatus, all held in place by bandages. These are kept in place five or six weeks, when the patient is cured. Massage will then be of help. Yet cases occur in which this treatment cannot be employed, when there are many splinters of bone, when the joint cavity is filled with effusion, etc. [M. O.]

3.—Verneuil has used ketene, pure chloride of ethyl, in 70 cases to produce general anesthesia. A special mask will be needed for its administration. Verneuil has thus far only used it in operating for a short time, changing to chloroform if the operation should be prolonged. The great advantage of chloride of ethyl is that it produces anesthesia at once, while ether and chloroform waste much time before the patient is anesthetized. It is even more rapid than bromide of ethyl. Nor do any disturbances follow its use. Verneuil forms no conclusions yet, as he intends making further experiments. [M. O.]

4.—Willems has collected 14 cases from the literature, in which the omentum was sutured to the abdominal wall in order to deplete the portal circulation by establishing an anastomosis of the blood vessels by which the ascites, in cirrhosis of the liver, will be relieved. In nine of these cases the effect upon the portal circulation was excellent, and recovery followed. Willems operated on a child of five years, with a large mesenteric tumor, without ascites. The abdominal wall was denuded of its peritoneum, and the omentum sutured to it. Both the spleen and liver decreased in size since. The child has been improving ever since the operation. Willems wonders whether this proceeding may not predispose to internal strangulation. [M. O.]

SLOW PULSE WITH SPECIAL REFERENCE TO
STOKES—ADAMS DISEASE.*

By ROBERT T. EDES, M. D.,

of Boston.

Continued from Page 271.)

Kusnezow (*Arch. Arch.*, p. 132, p. 1.) Changes in acute and chronic endocarditis. In acute endarteritis disease of the ganglia is observed in the form of inflammatory granulation formation, increase and swelling of capsule-endothelium, and albuminoid and fatty degeneration of the nerve cells themselves. The changes of the ganglia situated in the lower part of the auricular septum depend for the most part on a spread of the granulation process by continuity from the valves to the fatty tissue surrounding the ganglia. Pigment changes are not always physiological. Changes in the muscle substance do not stand in most cases in direct relation to the changes in the ganglia. It is only in rare cases that it is possible to determine in a pathologico-anatomical way the dependence of alterations in the activity of the heart upon diseases of the heart ganglia.

Winogradoff (*Cbl. f. Chir.*, 1884, p. 847). (*St. Pet. Med. Woch.*, *Beilage*, p. 54). Changes in the automotor heart ganglia in hereditary syphilis. Especially marked in the interstitial stroma of ganglia and accompanied by changes in the vessels and the connective tissue surrounding ganglia. Also (*Wiener Med. Presse*, 1886, No. 6). Changes of ganglia in pneumonia.

Wassilieff (*Cbl. Med. Wiss.*, 1876, p. 785). Changes in heart ganglia in lyssa. Shrinkage in capsules from edema.

Ott (*Zeitschr. f. Heilkunde*, 1888, p. 271). There are no ganglia in or upon the ventricles. They are in the septum of the auricles and also in circumference of auricles, their number diminishing as distance from septum increases. They are especially found in subpericardial connective tissue, but some are found imbedded in muscular substance.

Finds two types of alteration. First, development of connective tissue substances (progressive) met with under conditions which lead to congestion and changes of size in the heart.

Second, changes in the nerve cells (regressive) found in cases with more deeply acting qualitative alterations of blood (parenchymatous). Thirty-two cases were examined, in nearly all of which some form of heart disease was present, but among them no cases of very slow pulse. In most of them, where the clinical phenomena are noted at all, the pulse was rapid and frequently irregular. In a single one it is noted as slow and rhythmic. This was a case of chronic endocarditis, with chronic Bright's, etc. The heart was pale and flabby. There was increase and swelling of nuclei of the sheath of Schwann, also of round interstitial cells. There were many ganglion cells which appeared as if compressed by the sheath (im Schwanden begriffen). The protoplasm was finely granular. In some cells the nuclei were still visible, in others not.

In four cases where the degenerative changes in the nerve cells were very marked the pulse had been noted as follows:

Tuberculosis and many other lesions. Pulse, frequent, strong, rhythmic.

Pneumonia. Alcoholism. P., frequent, weak, rhythmic.

Acute atrophy of liver. P., frequent, weak, rhythmic. Phosphorus poisoning. P., frequent, weak, rhythmic.

The paper of Eisenlohr I have not seen, but judge from many references to it his results are much like those of Ott.

The two balancing systems of nerves which regulate the beat of the heart take their origin in the medulla oblongata, and, although in a manner opposing, their centres are probably quite near to each other. (Porter in *American System of Physiology*, 2nd Ed., p. 177.)

From this region they take different routes, that of the regulatory or inhibitory passing directly in the vagus to the cardiac plexus, while the accelerator or augmentor passes down the cervical cord to its lower portion, where it unites with the stellate ganglion formed by the union of the last cervical and first dorsal sympathetic ganglia, which in turn sends branches to the cardiac plexus. After the cardiac plexus is formed by the union of the two nerves on each side, joined by some smaller filaments from the upper ganglia, it is impossible to say from what source any special bundle is derived. The cardiac plexuses are united with the intrinsic ganglia of the heart situated as already described, breaking up into smaller and smaller branches, and are distributed plentifully over the heart muscle.

Anatomically the heart muscle agrees neither with the smooth nor with the voluntary muscular fibre and physiologically stands between them. Although having striae like the voluntary muscle, a structural condition undoubtedly connected with its capacity, or rather necessity, for rapid contraction, yet it may contract, not only many times but rhythmically, without any new stimulus from the nervous centres and, so far as can be seen, without assistance from nerve cells and perhaps even without any nervous fibres.

As the heart is simply a portion of a hollow tube surrounded by muscle for the purpose of propelling the fluid contents to the next segment beyond, each of its beats may be looked upon as the analogue of a limited peristaltic wave, such as propels the contents of the intestinal canal or the ureters, but differing from these in the very essential point of rapidity of propagation.

It is very probable that the intrinsic ganglia are to be looked upon not as exactly automotor, in the sense of initiating independently the cardiac cycle, as has been assumed by many writers, nor, on the other hand, as exclusively sensitive, as it is urged upon embryological grounds (vs. Romberg and His.) they should be, but reflex centres controlling the proper succession of impulses.

They are thus akin to the local regulatory centres connected with various organs like the ophthalmic ganglion with the iris, but more especially to the plexuses of Meissner and Auerbach in the intestinal walls.

Although it has been conclusively shown that the muscle of the ventricle does not require a nervous impulse from the auricle in order to contract and even to beat rhythmically, yet the nerves passing

from the cardiac plexuses over the auricle to the ventricle are necessary for the proper correlation of their beats and making their contractions effective in propulsion instead of disorderly and confused.

These small ganglionic centres to which the nerve fibres of the auricles and ventricles stand in the relation of afferent and efferent conductors are under the control of both the vagus and the sympathetic, the latter perhaps supplying a constant portion of potential energy or, in other words, keeping up their reflex tone, and the vagus controlling its discharge and regulating the intervals at which it shall take place.

In the table containing the cases which present the typical Stokes-Adams symptom-group during life and which were examined post mortem, there are to be found three (Nos. 4, 9, 31) where a distinct lesion of the bulb or the cervical portion of the cord was found, or four, including the horse (No. 35).

King (*Lancet*, 1845, Vol. II) states that a lesion in this region is the "only known cause of slow pulse" and brings forward a considerable number of cases where a slow pulse was connected with such a lesion, most of which, however, were not subject to the exacerbations which mark the type. He admits, however, that there are other possible causes.

We can say, as to brain lesions, that intracranial pressure frequently produces a certain amount of lowering of the pulse rate, but seldom of an extreme degree, and also according to Mr. Hutchinson, irregularity. This kind of slow pulse may arise from lesions differing in kind and position, but probably all producing ultimately a pressure on the bulb.

Table 2 makes no pretence to completeness and it could undoubtedly be considerably extended by a reference to surgical records of injuries to the cervical vertebrae, as well as medical reports.

The objections to considering the permanent slow pulse, whether existing as a single symptom or making a part of Stokes-Adams disease, to be dependent upon irritative lesions, involving the origin of the vague or of its inhibitory fibres, are the following:

A constant irritation rarely lasts so long and with so little change in character as happens in these cases. Some paralyzing degenerative lesion is much more naturally looked for.

In health the pneumogastric's function is to hold down the pulse within certain limits, in order to secure the most advantageous rate of expenditure. It is a sort of check upon and not an opponent to the activity of the augmentor nerves. In experiments upon mammals it is never possible to completely hold down the pulse for any length of time by stimulating the vagus. After a short pause the heart begins to beat again slowly and then resumes its usual rate or assumes a new regular rate, even while the stimulation of the vagus is still going on.

The alkaloid atropine is known to paralyze the inhibitory function of the vagus from one end to the other. If atropine is given in a case of slow pulse dependent upon intracranial lesions irritating the vagus, it quickens the pulse materially, but in the cases of permanent slow pulse it produces at most only a very slight effect or none at all. (*Dekio, St. Pet. Med. Woch.*, 1892, No. 1.)

It is singular that this well-known property of atropine should not have been utilized for diagnosis before. Atropine and belladonna are recorded as having been used in a considerable number of cases without benefit, but the special diagnostic significance of this seems to have been overlooked.

A lesion in the course of the vagus was found in one case (No. 8) and possibly in No. 1 of the first table.

In case 14 the authors consider the degenerative vascular changes in the brain, which they found most marked in the cerebellum, to be the most important. It will be seen by noting the condition of the brain found in many other cases that leaving out of consideration the general atheroma which is so frequently found when no definite symptoms, or varying symptoms of all kinds, have been present, and which (the atheroma) may or may not have involved the nutrient arteries of the bulb, we have nothing by which to connect any special intracranial lesion with the rapidity of the pulse.

Taking the three cases of Table 1 with the larger number of Table 2, some of which are very clear and distinct, we find little to sustain the theory that the permanent slow pulse is the consequence of an irritative lesion of the bulb, but there appears a very evident connection with a lesion of the cord lower down, i. e., from just below the bulb down to the first dorsal vertebra. See Charcot (*Système Nerveux*, Ser. II., p. 135). A narrowing of the canal at the occipital foramen affects the cord rather than the oblongata. The cases I have quoted are lacking in a minute description of the histological changes, but it is evident in many of them from the absolute paralysis of sensation and motion below the lesion that all fibres were thoroughly involved. The lesion was in all cases situated above the point where the augmentor fibres leave the cord to join the compound or stellate ganglion on their way to the heart. There can then be little doubt of the existence of one group of cases dependent upon a paralyzing lesion of the augmentor nerve fibres within the cord.

Lesions of the stellate cervico-dorsal ganglia have not been observed in such cases, but these ganglia have been very seldom examined.

Fränkel (*N. Y. Med. Rec.*, 1900, June 16) reports a case in which he found these ganglia seated in small abscesses connected with a limited pleurisy, but the symptoms were not such as to have any bearing on our subject, being largely of a hysterical character. In Prentiss' case I examined them, but found nothing characteristic.

Hutchinson (*Lond. Hosp. Rep.*, Vol. III, p. 366) says that when there is a fracture of the spine high up the pulse diminishes in frequency and is remarkably large and full, and remarks upon the peculiar impression made by a man screaming with pain and a countenance expressive of the utmost suffering and anxiety, but whose pulse was slow, full and deliberate, forty-eight in the minute.

The cases remaining in Table 1 may be distributed as follows, with reference to the cardiac and vascular lesions as follows:

Class I.—Pericarditis. Case 5.

Class II.

Group 1.—Valvular lesions and simple dilatation.

Cases 24, 27, 28, 30, 31, 32.

Group 2.—Atheroma of aorta and general. Cases 3, 6, 7, 12, 14, 15, 17, 18, 22, 23, 24, 25, 28, 29, 30, 34.

Group 3.—Atheroma of coronaries. Cases 3, 12, 18, 21, 24, 27, 29, 30.

Group 4.—Degenerative changes of the muscle.
A. Fatty. Cases 6, 13, 16, 17, 18, 21, 22, 24, 26, 29, 30, 31.

B. Fibroid. Cases 19, 20, 29, 32 and 35 in Table 2.

Group 5.—Degenerative changes of ganglia. Cases 6, 32.

Class III.—Nothing decisive. Cases 1, 7, 10, 11.

In Case 1 neither the aorta nor coronary arteries were atheromatous. The heart was rather large and firm.

In Case 7 the coronary arteries were normal. The aorta was smooth, except a few small plaques of atheroma in the beginning of the thoracic and above bifurcation.

In Case 10 the results were completely negative.

In Case 11 the arteries were remarkably free from atheroma and the coronaries pervious.

The connection of slow pulse with general arteriosclerosis is an interesting and important but far from invariable one. It was found in my table in about half the cases, but it is well known that by far the greater number of cases of arterial disease are attended by no such symptom.

The same things are true of the muscular degenerations, especially the fatty, of which the more common symptom is rapidity and irregularity. The fatty heart of which Kisch (*Berl. Klin. Woch.*, 1885, p. 215) makes the moderately slow pulse a rather common symptom is that which is a part of general corpulence and has little to do with paroxysmal bradycardia. It is only dangerous when permanently down to 50 or 30, which is very rare.

Much weight has been laid upon degeneration of the coronaries, first as a known cause of the muscular lesions, and secondly as a possible cause of a possible ganglionic lesion. It is recorded in eight of the thirty-four cases. The connection is far from an invariable or even extremely frequent one.

Loomis (*Trans. Am. Climatolog. Assoc.*, 1892, p. 73) makes the statement that "post mortem studies teach that fatty degeneration of the heart is usually associated with obstructive changes in the aorta and the origin of the coronary arteries, while, as I have already stated, fibroid changes are usually associated with obstructive changes in the coronary arterioles." If this association is a frequent one and if the degeneration of the ganglia depends upon obstruction of the small branches of the coronaries, which go to feed the auricular walls, we certainly ought to find a very frequent connection of slow pulse with fibroid degeneration, which is not the case. Only two such cases are in our table. Hilton Fagge (*Trans. Path. Soc. Lond.*, 1874, p. 64), among eleven autopsies made by himself where the walls of the heart were in a condition of fibroid degeneration mentions two cases as having had a slow pulse, and among nineteen others found in the records of the society, finds two, which are those mentioned in my table. He says: "My cases, however, do not at all support the opinion that a slow

pulse is to be regarded as a constant or even a frequent result of fibroid disease. These are problems which are still looking to minute anatomy and histology for their solution."

The intrinsic ganglia of the heart have been examined in but very few cases of this kind, and in only one microscopically (Jona, Case 32). That was not a typical one, inasmuch as mitral stenosis existed, which is likely to exhibit an apparently slow pulse when the heart is beating at a normal rate; and, indeed, it is stated that the heart beat nearly twice as fast as the pulse at the wrist; but since the minimum pulse (22), even if nearly doubled, would still have been slow, and as other observers find lesions of these ganglia in specially frequent association with valvular lesions, it might have been supposed that there would have been degenerative changes of the ganglia. But the reporter, who made a very careful examination, is not certain that the slight changes, chiefly in the chromatin of the cells, indicated anything more than such functional ones as have been found in other nerve cells from fatigue. Here again we are met with the opposing fact that in a large number of cases in which both sclerotic and degenerative changes were actually found, the pulse was rapid and usually weak. (See Ott. loc. cit.) Further histological researches are required when cases presenting the appropriate clinical phenomena arise.

From a combination of the positive results of interference with the augmentor nerve fibres higher up in their course, i. e., from fractures and dislocations, and one or two cases of disease, and on the other hand the insufficiency of the common and obvious cardiac lesions to account for the phenomena, it may fairly be said that the permanent or continued slow pulse is the result of a paresis of the augmentor nervous system, depending either on a lesion anywhere in its course from the bulb down to and including the intrinsic heart ganglia, or on a localized weakness which in acute or temporary cases would probably leave no anatomical traces behind, and in no case very obvious ones.

In the medical cases, i. e., the strictly Stokes-Adams, it may be claimed with less confidence but still with considerable probability that the lesion is situated in the auricular ganglia and is of a degenerative character. It is likely to be dependent upon fatty degeneration of special small branches of the coronaries destined for their nourishment. Why the special symptom should be at one time a rapid and at another, much less frequently, a slow pulse is probably dependent on the extent and degree of advancement of the degeneration, but there is no more inconsistency involved than in the closely allied facts of degeneration of other nerve cells where we have absence of reflex excitability succeeding an increase, anesthesia to hyperesthesia or dementia to excitement.

In fact, the transition from rapid to slow has been noticed in some of these very cases, and also in connection with the action of certain drugs. A very notable case is one reported by Platt (*Tr. Am. Climatolog. Assoc.*, 1892, p. 59), where a young lady recovering from pneumonia had for a number of days a pulse which underwent very rapid transitions, by the dropping of successive beats, from a little above the

normal (110) to considerably below (48). In a last and more severe attack attended with much prostration and vomiting, the pulse, when it could be counted at all, went down to 40 or 50 for several hours until it changed to 92 and final recovery. In this case and probably in many which resemble it in everything except the rapidity of the transitions there is probably a good deal of pneumogastric influence at work.

The slow pulse existing when there is evident general debility and nothing else, as in convalescence, dropping below the normal together with the temperature for a few days, as well as the low temperature often connected with the chronic cases point to a condition of local cardionervous debility.

The augmentor system is in a condition of diminished resistance as regards the action of the pneumogastric, which is simply a regulator when the augmentors have their proper tone, but which when their resistance is pathologically diminished goes beyond the due balance of forces and produces the phenomena of the still slower pulse.

Whether the original development of these conditions is due to a simple progressive increase of degenerative changes which have imperceptibly reached the effective degree, or to a rapid exhaustion of nerve centres by excessive stimulation analogous to the dilatation of the heart muscle under excessive exertion cannot now be answered by anatomy. A sudden shock is capable, judging by symptoms, of producing impairment of function which requires days or weeks to recover from or which may be permanent, but it is not known at what point the slight temporary changes which have within the last few years been found in so many nerve cells as a consequence of fatigue, pass into the degenerative ones that mark a chronic disability.

Without regard to the anatomical findings there are some physiological observations which show a very close analogy between the formation of the slow pulse and those cases in which the intermediate beats continue to be feebly represented, and the action of the vagus. It was found by Chauveau (*Revue de Med. and Lyon Med.*, 1883), and also by Vaquez and Bureau (*Mem. Soc. de Biol.*, 1893), that certain small intermediate beats which could be seen in the cardiogram and synchronously with this in the jugular pulsations, were referable to auricular contractions which were not communicated to the ventricle, and this condition of things was compared to what is found when the vagus of the horse is weakly stimulated, that is the inhibition of the ventricular contractions while the auricular are but little affected.

Pouzin (*Paris Thesis*, 1898) gives the same explanation of the weak beats, and Bristowe (*Lancet*, 1885) also suggests it without coming to a decision. Of course this condition is fairly referable to the want of efficient reflex nervous connection between the auricle and ventricle, and it is not only possible but highly probable that this connection may be impaired not only by a permanent degeneration of the ganglia but by the temporary interference of the pneumogastric.

Moritz (*St. Petersb. Med. W'och.*, 1897, p. 301), describes a case where there was a jugular venous pulse of 76-78, with a radial of 30, and a number of

weak tones in the heart. He entitles this "One-sided bradycardia," and thought it ought to have been due to a syphilitic neoplasm at the ventricular septum, but it seems much more like another instance of auricular pulsations persistent after the ventricle has taken up a slower rhythm, i. e., that the heart was cut in two functionally in the transverse instead of the longitudinal direction.

It has been shown, as already stated, that the point of the heart, if fed, may be made to beat not only irregularly but rhythmically, but it is also found that when the ventricle has been "crushed off" by a tight thread the rhythm of the ventricle is no longer the same as that of the auricle.

Langendorff (*Arch. f. Anat. und Phys.*, 1884, *Suppl.*) even claims that such slight relations between the two segments of the frog's heart after the ligature, as are shown by a "regular succession of auricular beats," i. e., a number of auricular without effect on the ventricle, and then one auricular followed by one ventricular, which sends along a wave of blood through the aorta, is due to imperfect crushing that has spared some fibres.

Kronecker (*Verh. d. XI. Cong. Inn. Med.*, p. 525) also states that stimulation can be conducted (in a dog's heart) from auricles to ventricles by a single nervous bundle, and when this is ligatured the ventricles beat independently some three times slower, until death.

These temporary and experimental resemblances of action, however, do not remove one of the main objections to applying the vagus theory to the permanent slow pulse, namely, that its inhibitory action is short, and soon overcome by normal augmentors.

The paroxysmal manifestations of Stokes-Adams disease fit in much more easily with a theory of vagus irritation than does the permanent condition. Such a theory, applied only to the paroxysms, calls for no lesions, gross or microscopic, of the bulb, since it is only a reflex centre whence the inhibitory impulse takes its origin by transformation of any temporary sensory irritation within or without the nervous centres. A very interesting case given by Romberg from Heine (*Syd. Soc.'s Trans.*, Vol II, p. 340) at too great length to be quoted in full, shows the probable action of the vagus in producing a temporary cessation of the heart's pulsation.

A man, aged 36, stated that his heart often stood still. At his next visit he was able to demonstrate the fact, for there was an intermission of five or six of the heart and of the pulse. The aspect of the patient showed, that at the time something terrible was going on within him; he sat there as if thunderstruck, speechless, motionless, his eyes wide open, his consciousness unimpaired. He had a violent pain at these times on both sides of the thorax, extending to the neck and head. He knew of nothing except mental emotions, which had a tendency to produce the attacks, which were much more frequent on some days than others.

The most accurate examination of the heart during the free intervals, failed to demonstrate any abnormality in the rhythm, the sounds, and the extent of the cardiac dulness. He lost strength, had vertigo, and died in a state of sopor.

The autopsy was made with great care by Rokitsky.

The nervus cardiacus magnus, which ascends from the plexus lying between the descending aorta and the pulmonary artery, was woven into a black knot of the size of a hazelnut by the lax, pale greyish cords forming the cardiac nervous plexus; before its entrance into the knot the nerve was thickened. The branches of the left vagus which descend upon the anterior side of the left bronchus to the pulmonary plexus, proved to be dragged in the same way by an underlying nodulated dark blue, lymphatic gland. The heart was of the usual size and tough. There were other enlarged and cretaceous lymphatic glands, one of which interrupted the phrenic nerve. The solar ganglion was very large. There were many pathological changes in the brain and cervical spinal cord.

Debove (*Soc. Med. des Hop. de Paris*, 1888, p. 441) reports the case of a patient whom he had observed for some years with a pulse of 36, who died in syncope. Nothing is said of the presence of any paroxysm previously. The bulb was found perfectly healthy, the pneumogastric nuclei being specially examined by the microscope.

The pneumogastric is more effectual in reducing the activity of the heart's beat in proportion, "as the augmentor system is weaker." It is possible to greatly slow or even stop the heart in a weak animal by the use of a stimulus which in the vigorous is unable to do more than cause a comparatively slight and transient slowing followed by a rapid and immediate escape. The heart of a dog or cat weakened by repeated inhibition very frequently toward the end of the experiment shows itself unable to escape effectively to a regular rate and force of beat." (Hough, *Journal of Physiology*, 1893, p. 161.)

These physiological observations show how the paroxysms in a case of slow pulse may be developed by causes which, acting against augmentors of normal resistance, would be inoperative.

If there were any increased reflex susceptibility on the part of the vagus, it would of course increase the intensity of the phenomena, but such an increase is not demanded by the hypothesis.

Some very suggestive experiments by Mayer and Pribram (*Sitzber. der Wien. Akad.*, 1872, p. 104) illustrate the efficiency of what is, in such cases as we are able to assign any definite cause, one of the most common causes of the paroxysms, i. e., digestive disturbances. By the aid of the usual registration methods they determined the action of gastric irritation in increasing the general vascular tension and in lowering the rate of the pulse. This seemed to be due more to action upon the muscular and serous coats of the stomach than on the mucous, for irritation of the latter by chemical irritants or by cold had no effect upon the pulse, while with electrical or mechanical applied to the outside it was decided.

An observation interesting as most closely simulating that condition which holds so prominent a place among our "gastric griefs and peristaltic woes," i. e., flatulence, depended upon the introduction of a rubber balloon into the stomach, and as

the dilatation of this increased and diminished, so did the vascular tension, while the frequency of the pulse varied in the opposite direction.

It would be very desirable to apply the atropine test during the paroxysm for the purpose of deciding in each case how far the two factors of weakened augmentors and irritated pneumogastric might be involved, but so far as I have found this has not often been done with a view to diagnosis. I regret extremely that I have not done it myself when the opportunity offered. One case, however, seems to be in accordance with the theory.

Kinkead (*Dubl. J. Med. Sci.*, 1898, p. 4) was called to see a man who was taken sick one evening with faintness and pain in the stomach, but without vomiting. The pulse was at first regular, but after another attack of faintness it became intermittent. The next day he vomited and had acute pain on pressure just below the ensiform cartilage, and the pulse had fallen to 6 per minute. The physician watched him for an hour, phonendoscope over heart, finger on pulse, and watch in hand, while the pulse beat at this rate. Atropin was injected hypodermically and a mustard leaf placed over stomach. After about an hour the faint feeling passed off, the pain at the pit of the stomach got better, and the next morning the pulse was 72. One cannot help regretting that he did not watch with the phonendoscope during this hour of recovery.

A day or two later there was a little tendency to irregularity, the joints became painful and swollen, but were relieved by salicylate of soda, after which there was no further trouble.

After looking over a considerable number of cases one finds that the origin or causes of this condition stated, are so vague or so general in the great majority of them, that any attempt at statistics would have only an apparent precision. But it seems quite evident in looking at the list of cases with autopsy that essentially the same causes have been at work as in the degenerative diseases of the heart in general, except so far as valvular disease, the result of acute rheumatism, is concerned as an important factor, and even this is not entirely absent. The wear and tear of life in general are undoubtedly not without their effect, and alcohol, also, but bradycardiacs are not to be found especially numerous among those who have suffered more than their neighbors, nor, on the other hand, among those who have drowned their sorrow in the flowing bowl. Severe bodily efforts, not necessarily extremely prolonged, and mental or emotional strain, come the nearest to being frequent causes. The first of these is interesting in connection with the observations of Allbutt, DaCosta, Leyden and others, where great strain with heavy weights and under conditions involving fixation of the thoracic muscles, is a potent cause of dilatation and disease of the heart, but entirely without the clinical phenomena of the cases now under discussion. The latter, i. e., psychic, causes have an interest as being frequently invoked in the origin of a condition almost the opposite, that is, Grave's disease with its extremely rapid pulse. It would seem as if certain shocks bringing to bear a strain upon the heart and finding it in a condition of unstable equilibrium, were liable to disturb its rhythm in either direction.

Is the determining factor in such cases an augmentor paresis already present or closely impending?

A case reported by Strübing (*Deutsch. Med. Woch.*, 1893) is a very interesting one as showing quite clearly the origin of a well-marked instance of this kind at a much earlier age than usual.

A boy of 15, well built and nourished, was fairly well and strong except that he did not easily keep up with the other boys in running. On one occasion he ran a considerable distance, not to be late at school, was attacked by vertigo, and his face grew pale. He fainted and lost consciousness, but after awaking with a headache, walked home and went to bed, where he had another attack with loss of consciousness and convulsions. This was the beginning of a series of attacks which involved no dyspnea or palpitation, but vertigo and headache. The heart was enlarged. The pulse usually 16-18, the contractions not of the same strength or same interval, dicrotic, (dicrotism is very rarely if ever seen in a well-marked case of this kind and in the tracings given in this, although, to be sure, they were taken at a later period, there is not the slightest trace of it). There were several occasions of improvement and a falling back, psychic excitations being of distinct effect in bringing on severe symptoms with a pulse of 14- or 12. With great care, especially as to effort, the pulse gradually rose to 44 at one time, but there were other relapses, and he finally died. At last a systolic murmur developed.

In Prentiss' first case there had been heavy lifting. Other cases are to be found in the tables.

In the etiology, as well as in other points, we find the weak heart with slow pulse coming very close to the weak heart with rapid and irregular pulse. Leyden (*Ztschr. f. Klin. Med.*, 1886, p. 105), after speaking of the symptoms of heart disease arising from over-exertion, including irregular pulse and "pulse more frequent or easily made so," mentions a rare group of cases of exhaustion connected with a slowing of the pulse to 40 or 30, and gives several cases. Sexual excesses are mentioned in a general way by some writers. My own experience would not point strongly in this direction, and I have found it mentioned distinctly but once in connection with the special case. There is no reason, of course, why it should not be placed among other depressing agents.

Saurel has written a thesis (Paris) on the permanent slow pulse in general and in particular in "surmenage et l'anémie," but his cases relate more definitely to the latter factor.

Prognosis.—The moderately slow pulse of convalescence or in the course of acute diseases, especially in rheumatism, is particularly of little importance, not adding to the gravity of the cases, as judged by other symptoms. It is usually quite temporary under these circumstances. The same may be said of its occurrence with a slightly lowered temperature in mere debility.

The permanent slow pulse should lead to careful inquiry into the condition of the heart, and the presence of nervous symptoms, even so slight as transitory vertigo would materially affect the prognosis. There are a good many of what may be

called acute or subacute cases, which improve not only as regards the nervous symptoms, but also in the frequency of the pulse within a few days or weeks. They are usually cases which originate in some special strain, and the recovery is complete.

Another group, and these are especially elderly or aged persons, get rid of the nervous symptoms and, living a moderate life, experience no inconvenience from the slow pulse, which remains the same. They are not, however, to be looked upon as completely well, and are liable to a return of the paroxysms under bodily or mental stress or even without special known cause. (Case IV.) The cases where very slight nervous symptoms still persist are to be classed with these.

In the fully developed disease, where the nervous symptoms remain, but perhaps leave the patient fairly comfortable in the interval, are eminently uncertain. No insurance company should look at them for a moment, and yet the cases are by no means unknown where they live for years.

An instance, however, is reported by Flint (*Am. Pract.*, Vol. 13, p. 1), in which a man whose pulse was supposed to have been slow for many years, and who had epileptiform convulsions, was not only looked at by an insurance company, but accepted, nine and eight years before Dr. Flint saw him. A little doubt is thrown upon the genuineness of this case as an instance of Cheyne-Stokes, by the fact that in the convulsions the pulse became rapid instead of slower.

Some writer has mentioned three and a half years as the probability of life, but a calculated average of that kind can have very little value, except as an item of statistics. The study of the individual case and, in particular, the severity of the symptoms and condition of the pulse during the paroxysms, would give much more important results. The great majority of such cases die during a paroxysm. The longest period I have seen mentioned was in a case of Osler's, 30 years.

Huchard calls attention to three sets of cases. Those in which there is no permanent slow pulse, but which correspond to the type in the occurrence of the nervous attacks, the pulse at the time being slow. In these it may be supposed that the accelerators, while sufficient to carry on the beats at the ordinary rate under ordinary circumstances, are so near the point of yielding that the vagus easily overcomes them.

Those in which the nervous symptoms are but slightly marked, transient attacks of vertigo or weakness.

What he calls "associated," which are simply the occurrence of Stokes-Adams with something else, without any special connection between them, or at least only such as is very common with other forms of heart disease, either the renal setting up the cardiac, as happens in some cases, interstitial nephritis or vascular degeneration lying at the foundation of both; or, on the other side, the kidney suffering from congestion. Such a case is reported by Whitridge (*Boston Med. and Surg. J.*, 1900, 329).

An important therapeutic observation gives rise, as has happened often enough before, to rather a loose piece of pathological classification. Several cases are called uremic, in which this diagnosis

rests solely on the scanty urine and the great improvement which takes place on a milk diet and consequently increased excretion.

The treatment of the permanent slow pulse consists in rest, which is to be more or less complete according to the special case, from the most absolute upward. Diet, tonics and such regulated exercises as have been found beneficial in other forms of heart disease. Cardiac tonics have been found of some value, although there is no specific. The nitrites have been favorably mentioned in some cases. Digitalis, the beneficial action of which in most cases of heart disease, consists in its slowing the pulse, has in a few cases resulted in quickening that which is already too slow, an action which it is not difficult to understand when we recollect that the tonic action of this drug consists not only in increasing the activity of the pneumogastric and the vaso motors, but to a certain extent that of the augmentors also. In these cases it may happen that the balance is so adjusted that the latter effect outweighs the former.

Belladonna has proved a distinct failure for the treatment of the permanent slow pulse.

The prophylaxis of the paroxysm consists in carefully adjusting the load to the weakened muscular system that has to carry it, and in avoiding the causes of exciting the reflex activity of the vagus, in particular, muscular strain and digestive disturbance. The bromide of potassium has been suggested on theoretic grounds to diminish reflex activity.

In the developed paroxysm cardiac stimulants like ammonia and the nitrites, are to be used, and especially atropine, which should be given subcutaneously in the dose of one or two milligrams. It has been remarked that the cases are not numerous in which the action of atropine given in efficient quantities has been carefully watched. In the case of Kinkead, it seems to have acted as it should do theoretically, and also in the case of Claybaugh, relieved the earlier paroxysms. The recumbent posture of course favors the return of blood to the brain. One of Stokes' patients found that he could ward off the fits by getting on his hands and knees and allowing his head to hang down.

THE INTIMATE ACTION OF THE SILVER NITRATE INJECTIONS IN THE TREATMENT OF PHTHISIS.

By THOMAS J. MAYS, A. M., M. D.,
of Philadelphia.

Professor of Diseases of the Chest in the Philadelphia Polyclinic, and
Visiting Physician to Rush Hospital for Consumption.

One hears a great deal about the unsatisfactory state of our knowledge concerning medicinal action; about the blindness with which drugs are administered, and about the disappointing results which they often yield. This arraignment is so true that it needs no special verification. Nor is the reason for its existence far to seek. Therapeutic theories, like other hypotheses, are prone to move in ruts which become so staid and worn that it often costs a struggle to step beyond their bounds, and when this is undertaken the innovator is often pilloried as being bold, unscientific, and even tinged with blind prejudice. It is forgotten that the mutations of time lay waste many times both theory and dogma, and that nowhere is this change more lamentably and pathetically evident than it is within the domain of medicine itself. No one would have dreamed, for example, that within the comparatively short space of a few months our ideas regarding the contagiousness and propagation of yellow fever would be shattered so completely and so hopelessly as they have been. If a few years ago any one would have been rash enough to question the orthodox belief that the yellow fever germs are lurking in the clothing and bedding of yellow fever sufferers, and that they are directly transmitted to the healthy through contact, and would have made an effort to give his views practical expression, he would have placed his life and limb in serious jeopardy. Yet so transparent and feeble was the foundation on which the universally accepted and powerful dogma rested that it merely required the prick of a mosquito to puncture and to destroy it. This instance is not cited with a view of discrediting or of reflecting on the advancement of medicine, for he who estimates scientific progress rightly realizes full well that this is exceedingly slow, and comes only through the crumbling and deterioration of much of the work that paves the way for its final consummation, but only for the purpose of showing the infirmity and evanescence of many ideas which we highly revere and believe impregnable, and of demonstrating the wisdom of toleration and liberalism towards other views and theories. That which is true of medicine in general in this respect is particularly true of phthisio-therapy; and the writer expresses the belief that one of the principal causes which is responsible for the present lamentable decrepitude in this special field is the bacillus-etiology of pulmonary consumption. Not only has it proved itself an accomplished failure as a remedial helpmeet, but it has been the active cause of misdirecting and of wasting a great deal of mental energy in the sphere of pharmacologic research during the last fifteen years. Its discovery was at once welcomed and eagerly accepted by many members of the profession as the responsible head of phthisis, the writer being included among the latter, and it instantly inspired the almost universal hope that it would lead to the development of new therapeutic principles, the practical application of which would extinguish the

FIGURE 2.—Slow Pulse.
(To be concluded).

worst plague in the history of medicine. Instigated by the logic that the bacillus is the cause of consumption, and that eradication of the former would exterminate the latter, every conceivable agent or influence that gave the least promise to efface this microorganism, was invoked. Antiseptic inhalations of carbolic acid, fluorine, iodine, creosote, sulphurous acid, formaldehyde, of the oils of cinnamon, peppermint, and cloves, of superheated air, of bacterial sprays to antagonize the growth of the tubercle bacillus, the internal administration of creosote, carbolic acid, iodoform, aristol, asapol, creolin, guethol, guaiacol, ichthalbin, ichthyol, iodipin, iodole, thiacol, etc.; the hypodermic administration of tuberculin, anti-phthisin, serum of every description; and lastly, the somewhat famous enemata of sulphuretted hydrogen. Among the above-named remedies which created the widest, and perhaps, a world-wide interest, were creosote, tuberculin, the serums, and Bergeon's method; yet at the present day, with the exception of creosote, one scarcely sees a serious reference to any of them as remedies in this disease. Beaten from pillar to post, the bacillary therapists were finally forced to acknowledge tacitly that neither the bacillus nor its toxin can be destroyed, and are now obliged to fall back on the secure position that bodily resistance, nutritious food, and fresh air are, after all, the essential elements in the treatment of the disease under consideration.

After this preliminary digression, the writer will discuss the physiologic and therapeutic behavior of the hypodermic injection* of silver nitrate over the vagi in phthisis, a method which he has evolved and tested during the last three years, and which he believes has claims on the scientific attention of the profession. The hypothesis on which this treatment rests is that pulmonary phthisis in the large majority of cases is primarily a neurosis, in which the vagi participate, and that the pulmonary disintegration is secondary; and that direct stimulation of the vagi favorably influences the condition of the lungs. For is it not a common practice to apply a stimulating fly-blister to or near the roots of the nerves which are involved in sciatica, intercostal neuralgia, herpes zoster, etc., and is it not fair to assume, therefore, that a similar favorable impression may be made on the lungs through excitement of the vagi, their most important nerve supply? That nerve energy is enhanced by pressure or irritation when locally applied is well shown by the experiments of Zederbaum,* who found that moderate pressure applied directly to the sciatic nerve elevates its function of transmitting impulses to muscle, while greater pressure diminishes and inhibits the same. It has also been demonstrated by the writer** that mini-

mum doses of most of our important drugs enhance and strengthen the contractions of the isolated heart, and that maximum doses of the same drugs depress and inhibit the function of that organ, as is well illustrated in the following tracing which was produced by the action of sodium hydrate:

Blood sol. 1:40,000 1:1,000
Figure I. Showing the contrast between the effects of a 2 per cent. solution of blood, and minimum and maximum doses of sodium hydrate

The minimum dose of this drug was found to be 1:40,000, i. e., one part of sodium hydrate to forty thousand parts of a 2% blood solution, and the maximum dose 1:1000; and the tracings which they yield demonstrate that the addition of a minimum dose of sodium hydrate to the blood produces larger heart beats and higher tracings than are given by the blood alone, and that a maximum dose arrests the heart in systole. This may be regarded as positive evidence that sodium hydrate when administered in suitable doses is capable of pushing the function of the heart beyond the point which it can exert when fed by blood alone. That which is true of sodium hydrate was found to be true of aconitine, alcohol, ammonia, brucine, caffeine, chloroform, cocaine, curare, ether, pilocarpine, potassium, quinine, strychnine, and of all the principal drugs in the materia medica. In these experiments the heart is not to be regarded as a circulating medium, but as an organic medium of vital simplicity and tenacity with which the fundamental action of therapeutic agents may be demonstrated and measured. Further investigation showed, and this is the point of special interest here, that minimum doses of many drugs are direct antagonists to maximum doses of other drugs. For example, a maximum dose of alcohol, which was found to be one part to twenty-five parts of blood, paralyzes the action of the heart almost entirely, but when the minimum dose of atropine, which was found to be one part to one hundred and sixty thousand parts of blood, is added to this dose and administered at the same time, the tracings are nearly as high under this combined influence as they are under the influences of minimum doses of atropine, or under blood itself, as is seen in the following tracing:

Atropine. 1:160,000. Alcohol. 1:25. Their combined effects.
Figure II. The first part gives the effects of minimum doses of atropine, the second part of those of maximum doses of alcohol; and the third part the combined effects of a minimum dose of atropine and a maximum dose of alcohol.

A similar antagonism to that of atropine and alcohol was found between aconitine and ether, curare and ether, atropine and chloroform, aconitine and chloroform, strychnine and chloroform, curare and

*DIRECTIONS. Select for injection a point immediately over, or slight ly behind, the pulsating carotid artery in the neck, between the angle of the jaw and the clavicle. Lift the skin between the thumb and forefinger of the left hand and puncture only immediately through the skin. Inject five minims of a 2½ per cent. solution of cocaine hydrochlorate, detach the syringe from the needle and let the latter remain in the puncture. Wash out the syringe with water, draw a 2½ per cent. solution of silver nitrate into the syringe, attach the latter to the needle and throw in 5 minims of same. Or if cocaine nitrate can be secured mix 6 grs. of this and 6 grs. of silver nitrate with half an ounce of water and inject 10 minims. This is a preferable method, but as yet there is very little cocaine nitrate in the market. As a rule most of the injection should be given on the side below which the affected lung is located.

*Nervendehnung und Nervendruck. Von Dr. Ad. Zederbaum. Archiv fuer Physiologie, 1883, p. 161.

**The action and antagonism of some drugs on the frog's ventricle, by Thos. J. Mays, M. D. Therapeutic Gazette, February 16, 1885, p. 73.

pactions, it will finally be forced to seek a new or another state of equilibrium, in which it will remain after the attacking force has ceased to act. Such a result is well illustrated by the following phenomena: When a gentle gale blows over a field of wheat the wheat stalks are generally blown into a leaning position which tends to become more or less permanent, but a steady wind applied afterwards from an opposite direction will cause the stalks to become straight again and to resume and to retain a normal position after the latter force has ceased to operate. It is, therefore, by regarding these agents or forces acting on the effects of the forces of disease, that we find an explanation of the mechanism that improves the integrity of a nerve when it is irritated or compressed, as in Zederbaum's observations, or when a blister is applied near it, as in sciatica, or herpes zoster; or when nitrate of silver is injected over it, as in pulmonary phthisis. For just as the convulsive muscular movements and the cramps in the legs in sciatica, the numbness of the skin, the formication and bullar and pustular eruption in herpes zoster, are the legitimate sequence of nerve disintegration, so the pulmonary manifestations in phthisis are chiefly the result of vagi degeneration; and just as the two former diseases respond to medication that is applied locally to the nerves in question, so does pulmonary phthisis yield to counterirritation of the vagi in the region of the neck. In the further practical application of our subject, it may be said that alcohol has a special affinity for the nervous system, and frequently produces what is known as alcoholic neuritis, and that chronic alcoholism is frequently followed by pulmonary phthisis, in which disease of the vagi and of the peripheral nervous system coexists. In my work* recently issued a number of post mortem cases of this kind are given (p. 61), in which the vagi were degenerated. In my clinical work during the last few years I have frequently seen the most favorable results follow the injection of silver nitrate in alcoholic phthisis. To my mind it does not require a very extended stretch of the imagination to see the possible connection between the influence of the silver-injections and the favorable effects on the lungs in alcoholic phthisis. The disintegration of the pneumogastric nerves produced by maximum doses of alcohol is antagonized by stimulant or minimum doses of silver nitrate, or, in other words, the latter overcomes the effects of the former in the same way as a minimum dose of atropine antagonizes the devitalizing effects of maximum doses of alcohol on the frog's heart. That which is true of the pernicious effects of alcohol so far as engendering disease of the nervous system, vagus and lungs is concerned, is also true of syphilis, mercury and lead, of the toxins of typhoid fever, diphtheria, measles, whooping cough, mumps, influenza and beri beri. Vagus disease and phthisis are also frequently associated with multiple neuritis, locomotor ataxia, epilepsy, hysteria, idiocy and insanity, and are commonly caused by any influence or condition that undermines the integrity of the brain or nervous system.* From all that has been said,

chloroform, aconitine and curare, atropine and curare, atropine and strychnine, and strychnine and atropine. In these experiments it is important to realize that it is not so much the drug as it is the dose of the same that plays the leading rôle in these phenomena of antagonism; for, since strychnine is an antagonist to atropine, atropine to strychnine, curare to atropine, atropine to curare, etc., the minimum dose of one drug is antagonistic to the maximum doses of many, and perhaps all other drugs. Moreover, the fact that one drug has the power of interfering with the action of another establishes the principle that a therapeutic force is capable of overcoming and of successfully resisting the action of other disintegrating forces. For if we look beneath the surface of these phenomena we find two forces at work, which, being properly adjusted, become antagonistic to each other in their action on organic tissue—the one tending to enhance or to elevate, and the other to depress the function of the latter. These antagonistic effects are displayed as decidedly as if they were produced by the mechanical forces of attraction and repulsion, and they give us an exact and measurable idea of the power which drugs exert in supporting and preserving life when attacked by adverse forces. If we admit that disease is but the manifestation of morbid forces—forces which move in a direction inimical to health—and if we agree to substitute for these the influence of maximum drug doses as given in the above illustrations, we have a clear picture before us as to how drugs combat disease, viz.: by interference or antagonism. Now what is the mechanism of antagonism? What is the intimate nature of the combat between drug action and disease? In a broad dynamic sense it must be remembered that all the textures of the body are in a state of molecular motion, maintained principally by the internal chemical changes which the food undergoes, and that so long as the molecular motion of each texture harmonizes with that of every other, health is the result; but that as soon as perturbation arises among anyone or a number of these forces the condition which is known as disease follows. How then do antagonistic forces like drugs restore or augment healthy molecular motion? In other words, how does compression or irritation of a nerve, as in Zederbaum's experiments, enhance the function of nerve and muscle? or, how do minimum doses of drugs increase the contractile energy of the heart? Let us say, for example, that when gentle friction or massage is applied to a group of tired muscles, as of the arm, molecular activity of the latter is greatly increased. In this instance we see the antagonism of two kinds of forces—the force of friction, and that inherent in the tissues—moving in different or antagonistic directions, both of which being governed by the same physical laws, viz.: if one force acts on another it always calls for a corresponding reaction. Then when two forces of equal strength meet each other from opposite directions rest is produced. When two forces of somewhat unequal strength come in conflict with each other, the stronger causes the weaker to move in a direction parallel to its own, and to a point where a mutual balance takes place; and although the latter may tend to rebound and to assume its former position, yet, through the operation of a series of such im-

*Pulmonary consumption, pneumonia, and allied diseases of the lung. By Thomas J. Mays, A. M., M. D. Published by E. B. Treat & Co., New York, 1901.

*For a fuller elucidation of this subject see Author's book (loc. cit.) pp. 61-114.

we may conclude that the mechanism of the silver nitrate injections is of such a nature that it arouses the vagi from a feeble to a more vigorous station, and that in this way they create an antagonism to disease which diffuses itself throughout the extensive ramifications of these nerves.

PELIOSIS RHEUMATICA.

By T. AVERY ROGERS, M. D.,

of Plattsburgh, N. Y.

President of the Clinton County Medical Society.

This disease was first described by Schönlein and is sometimes called Schönlein's disease. The patient usually has the prodromal symptoms of an acute infection, malaise and fever, followed by symptoms of articular inflammation as met with in ordinary articular rheumatism. The knees, ankles and wrists are the joints more commonly affected. In a short time, from a few hours to two or three days, a purpuric eruption appears, which remains for a time, when the blood is gradually absorbed and the petechial spots disappear as after ordinary contusions or extravasations. Fatal hemorrhages in this disease have been reported by Kaposi. This disease is said to be most common in young women from 20 to 30, although Osler says it is most common in males of this age. Rheumatism is said to predispose, as well as malaria, and other infectious diseases. Finger has reported the discovery of cocci during the course of the affection.

Opinion has differed greatly among different observers as to the cause of the disease. Some think it is rheumatic in origin, others think it due to systemic affection from a coccus peculiar to itself. It is certainly generally conceded that it sometimes occurs during the course of, or following acute infections.

The case which I am about to report seems to uphold the theory that in some cases at least the cause is a systemic infection from the presence of a pyogenic focus.

Edema is sometimes a very marked symptom, and large quantities of albumin are sometimes present in the urine.

Treatment, as a rule, does not seem to shorten the course of the disease. This should be symptomatic, as in the absence of complications recovery is usually rapid.

Mrs. A. F., age 19. Has had two children, older three years. Baby died three months ago, aged one month. Patient has always had very good health, and has been free from any serious illness, including rheumatism. She is a marked blonde, and a slight, delicate woman. On December 29, 1900, she had some fever and malaise, resulting in a few hours in severe pains in both ankle joints with heat, redness and swelling. She did not come under my observation until the next day. The physician who had her in charge at this time applied the usual remedies for acute rheumatism. The pain remained in the ankle joint for twenty-four hours when all symptoms of articular inflammation disappeared there and reappeared in the wrist joints where it remained for a few hours. After this all articular symptoms were absent. Coincident with the beginning of the articular symptoms a petechial extravasation appeared in small spots quite evenly distributed over the legs below the hips. This was dark red and was at first macular, later becoming papular and purple in color. It would not disappear on pressure. The spots were confined to the legs, with the exception of a few on the left breast. They were not more common over the affected

joints. Itching was severe, and when scratched a line of subcutaneous extravasation of blood was visible. The most interesting symptom of the disease from the beginning was violent cramp like pains through the abdomen. These resisted treatment and were frequent for a week, when they disappeared. After a violent paroxysm of pain an attack of vomiting would relieve the patient for perhaps half an hour when another attack would occur. The stomach would not retain water or food any time and evidently did not digest or absorb very much in spite of the fact that peptones and easily digested foods were given. Thirst was excessive. The kidneys secreted quite freely, but a small quantity of albumin was present in the urine for a week or two. There was a slight edema of the face, especially the eyelids. Constipation was obstinate and was only relieved by laxatives accompanied by enemas or suppositories. The amount of opiates given would not account for such severe constipation. The pulse and temperature were rather subnormal after the subsidence of the articular symptoms until convalescence. In eight days the vomiting ceased, the bowels became regular, appetite and strength returned, all pains stopped, and the extravasations of blood gradually became absorbed.

The treatment was occasional hypodermics of morphine for the pain and vomiting, also bismuth and occasionally a slight amount of cocaine for the vomiting. Strychnine sulphate, gr. 1, 30 was given t. i. d. Bromide of potassium was given every 4 hours in ten grain doses. Three months previous to this attack the patient had suffered from an abscess of one breast which was lanced by the physician in charge. The wound soon closed and the breast gave the patient no further trouble. Two or three weeks after this attack of peliosis the wound opened and discharged slightly. In this case it seems to me that this suppurative condition was an etiological factor in the attack of peliosis rheumatica.

IS THE CENTRAL FISSURE DUPLICATED IN THE BRAIN OF CARLO GIACOMINI, ANATOMIST?

A Note on a Fissural Anomaly.

By EDWARD ANTHONY SPITZKA,

of New York.

Student of Medicine, College of Physicians and Surgeons.

In an elaborate study of the brain of Professor Giacomini, the celebrated anatomist, G. Sperino (1) records a peculiar anomaly which the former was himself the first to describe, and so rare is this anomaly that its finding in this particular instance would be a remarkable coincidence. It consists in the alleged duplication of the central fissure (or fissure of Rolando) upon the right side of Giacomini's brain, the two fissures including between them a so-called "gyrus Rolandicus."

Although a score of such instances have so far been reported, it is doubtful whether all of these would bear a close scrutiny of the conditions presented by them. For instance, in the brain of Dr. W. I. Brenizer, a suicide, a duplicity of the central fissure appeared to be present and was so described. Subsequently, Professor Wilder revised this interpretation in a paper (2) read before the American Neurological Association, in which he concludes that the second fissure in question is in reality the postcentral.

In so far as one may base a view upon the illustrations and descriptions which Sperino has given of Giacomini's brain, the explanation of the conditions as they exist appear unsatisfactory, and in this instance, as in Wilder's case, the duplication of the central fissure is only an apparent one. In Figure 1 is presented a copy of the lateral surface of the right hemisphere of Giacomini. The nomenclature employed by Sperino differs somewhat from

FIGURE 1.—Right hemispherium of *Giacomini* (after Specino). The exposure of the insula is said to be an artefact. For explanations see the text.

the American terminology, and I therefore introduce a list of the necessary terms for comparison:

SPERINO.	AMERICAN.
S.R. S. Rolandicus	Central F.
S.R. 2 S. Rolandicus secundus	"Second" Central F.
G.R. G. Rolandicus	G. Rolandicus
R.C.S. S. Retrocentralis sup.	Postcentral F.
R.C.I. S. Retrocentralis inf.	Subcentral F.
S.M. G. Supramarginalis	Marginal G.
G.C.P. G. Centralis post'r	Postcentral G.
S.C.P. S. Subcentralis post'r	Transpostcentral F.
S.C.A. S. Subcentralis ant'r	Transprecentral F.
I.P. S. Intraparietalis	Parietal F.
R.P.A. R. Post'r Ascend. Sylvil.	Episylvian F.
A.A.T.S. R. Ant'r ascend. del Solco temp. sup'r. (or S. Inter-medio).	Supertemporal F.

imply absence of the subcentral since this fissure normally serves to separate the two gyres from each other.

Fourth, Sperino's mode of interpretation places the entire postcentral complex too far caudad to comply with the demands of the normal mesial relations, as can be ascertained from a study of the second plate, not reproduced here. Thus the dorsal end of the "second central" (S. R. 2) is not cephalad of the upturned caudal end of the paracentral fissure, a relation which the true central fissure constantly has. Furthermore, Sperino's *sulcus retrocentralis* su-

FIGURE 2.—Prouto parietal formation, same as in Fig. 1, but the designations are revised in accordance with the present writer's views.

While the configurations of the region in question are atypical and of unusual appearance, the interpretations made by Sperino appear to the writer unwarranted for the following reasons:

First, and most important, the subcentral (R. C. I.) is placed caudad of the episylvian (R. P. A.) which would be an anatomical impossibility.

Second, the marginal gyre (S. M.) is situated cephalad of the subcentral (R. C. I.) instead of caudad, which would likewise be in contraindication of anatomical facts.

Third, the immediate fusion of the postcentral gyrus (G. C. P.) with the marginal g. (S. M.) would

perior is confluent, over the dorsi-mesal margin, with an unmistakable intraprecuneal fissure (P. S.). Such an unusual mode of junction should at once call attention to the relative latitude of these fissures.

Convinced that Sperino's interpretations are erroneous and unsatisfactory, the writer has taken the liberty of naming the fissures and gyres in accordance with the demands of normal relations as nearly as can be (Fig. 2).

I. Sperino's alleged "Second central" is nothing more than an unusually long and confluent postcentral + subcentral. The dorsal terminus is bifur-

ated and embraces the caudal paracentral limb, a very common arrangement; the ventral end approaches the sylvian cephalad of the episylvian ramus.

II. The marginal gyrus thus preserves its normal bounds as it curves around the episylvian, while the alleged "gyrus rolandicus" is simply a well-defined post-central gyrus.

III. The fissure named R. C. I. (Fig. 1) is in reality the intermediate fissure (Jensen) more or less perfectly marking the boundary between the angular and marginal gyres.

IV. Sperino's R. C. S. (Fig. 1) is an insignificant junction of the parietal fissure with the transparietal (Brissand), a fissure which often appears as a dorsolateral extension of the intraprecuneal. The odd junction of the parietal, supertemporal and in-

comini (4), in 1882, there is an unquestionable duplication, with a supernumary Rolandic gyrus, as shown in Fig. 3, reproduced from the original woodcut. In stating that the dorsal terminals of both central fissures are in relation with the caudal portion of the paracentral lobule, Giacomini removes all doubt as to the identity of these fissures, especially as there exist in addition well-marked precentral and postcentral fissures in their normal relations.

termedial at a common point is, it must be admitted, quite confusing. The separation of the parietal from the postcentral, though quite unusual, occurred, for instance, on the left side of the elder Seguin's brain, and has also been observed by others.

Subsequent to the appearance of Sperino's account, a paper was read by G. Leggiardi-Laura (3) in which the alleged duplicity of the central fissure is discussed in its morphological bearing.

Leggiardi concludes that a true duplicity of the central fissure has not yet been demonstrated, and that its alleged existence in the twenty-three cases so far recorded depends upon a multiplicity of fissures in the parietal lobe, commonly found in brachycephalic crania. Such conclusions hardly seem justified to the present writer, for in the case of the imbecile, Alb. Battista, described by Gia-

comini (4), in 1882, there is an unquestionable duplication, with a supernumary Rolandic gyrus, as shown in Fig. 3, reproduced from the original woodcut.

THE FOUNDATIONS OF FAITH IN MEDICINE.*

By A. W. CRANE, M. D.,

of Kalamazoo, Mich.

Faith in the internal administration of drugs has divided the public and is far from uniting the medical profession. Among the laity we find all degrees and varieties of anti-medicine fanaticism, from the belief that the use of medicine is a denial of the power and wisdom of God, to the loudly reiterated statement that medicine is powerless to affect the body, and that mind is alone accountable for disease and cure. Another extreme is the patent-medicine devotee, whose faith in labels is matched only by the savage before his fetish. Unnumbered tons of patent medicines are yearly consumed, and medical superstitions are daily stimulated by countless pages of advertising. A sober majority, however, still have a faith in drugs plus doctors, preferring to mix their medicines with a certain amount of brains.

On the professional side we must recognize the influence of the elderly physician, whose favorite saying is that he began practice with a hundred remedies, and now uses three or four; and the influence of the surgeon whose lifted eyebrows and shrugging shoulders stimulate public distrust in medical science. We find, also, the young practitioner who panders to a certain class of the public by explaining on occasion that *he* depends mostly for treatment on diet, hygiene, electricity, massage, etc., thus insinuating that drugs are "out of date."

I will not catalogue the numerous medical quackeries and creeds. Let it suffice that the solid majority of the medical profession like the sober mass of the laity, have an abiding faith in the intelligent use of medicines. It is this class which should now and then reconsider the foundations of this faith and help to preserve the mental equilibrium of society.

I offer no new contributions to our knowledge of drug-action, but would briefly review the reasons for the faith that is in us.

Medical knowledge became science when it was considered in the same way that geology, botany and astronomy are considered. The susceptibility of living tissues and organs to chemical substances is a fundamental fact as irrefutable as any fact in mathematics. The world knows that sufficient quantities of chloroform, strychnine or morphine will produce such extreme alterations in bodily processes that death is the result. That lesser quantities will also produce alterations in tissue chemistry and organic functions is no less certain. Similar statements may be made of most other drugs. It does not follow, because a drug in large doses will cause death, that therefore in smaller quantities it will produce deleterious effects. It is well known that there is no line between poisons and non-poisons.

It is a question of dosage. Ordinary table salt may be taken in quantities large enough to produce death. Hydrochloric acid, a natural secretion of the human stomach and necessary in the normal digestion of food, is nevertheless labeled poison by every druggist. The secretion of the thyroid gland is absolutely essential to the development of the individual and the maintenance of health, and yet if it be secreted or administered in too large quantities its action is poisonous.

Exactly what alterations may be produced in the body by various substances has been partially answered by the record of the experience of many thousands of trained intellects from the time of Hippocrates to the present day. More precise and increasingly valuable answers are being given by patient experimentation upon animals. It is only by animal experiments that much further advance can now be made into this vast field.

The practical question affecting medical faith is whether or not the effects producible by various drugs can be used in combating disease processes and their results. For answer we may call to mind the extraordinary control of bodily processes which may be exercised by the humblest practitioner, by means of well-known drugs. This control, although for the most part temporary, enables the physician to secure some extremely valuable effects. He can regulate elimination of effete matters. For example, he can produce or he can stop sweating; he can increase or decrease the expectoration; he can cause and often relieve vomiting; he can alter the quantity, constitution, reaction and antiseptic properties of the urine; he can excite or check the movements of the bowels. The circulation is likewise obedient to his touch. He can produce at will a rise or fall in arterial pressure; he can steady or strengthen or slow or quicken the action of the heart. He can stimulate or depress the respiration, and increase or decrease the power to cough. Digestive processes, particularly those of the stomach, may be profoundly influenced. The constitution of the blood may be altered; the quantity of hemoglobin, the volume of red corpuscles, and the number of leukocytes are in most cases subject to the will of the physician. He can reduce the temperature in fever to any desired degree. He can quiet the nervous, and relax spasms. He may exercise a marvelous dominion over pain. There is no physical suffering which lies beyond the temporary control of the physician. He may cause a local anesthesia or he may impose a general insensibility to any surgical procedure, however severe. Further than this, he may supply lacking secretions and body substances, and produce results which are sometimes little short of marvelous. Iron, supra-renal extract, pepsin, hydrochloric acid, and thyroid substance are examples of this enlarging class. What can be more convincing as to the value of animal experimentation than the ability it has given the physician to transform the cretin idiot, that squat, hideous monstrosity of the museum, into the normal shape and mind of a human being. Such is the power of the thyroid extract over the secret metabolism of the flesh.

More brilliant, however, than the treatment of the patient, is the modern treatment of the disease itself. This department of medicine has saved and

*Read before the Michigan State Medical Society, Battle Creek, Mich., May 15, 1901.

will continue to save the human race untold and incalculable suffering and death. Such is the power which the physician can wield through the possession of the antitoxin of diphtheria, the anti-tetanus and anti-streptococcus serums, anti-syphilitic and anti-malarial drugs, prophylactic inoculations, and the great range of antiseptics. These classes of agents, although yet small, have wrought such a change over the face of medical science that our expectations of future developments are almost without bounds.

This control of body and disease processes by drugs is by no means the limit of the physician's resources in the battle with disease. He has a well-equipped armamentarium of agents other than internal medicines. But the fashion of the day is to exalt these other methods at the expense of medicine, until the physician in some quarters is made to feel almost apologetic for prescribing any more drug. As a profession we must remember that therapeutics is the highest and most difficult art in the whole range of medicine and surgery. The matchless science of diagnosis is but the handmaid of therapeutics. In the final analysis, the diagnostician finds the purpose and aim of his work to be the accurate application of agents to combat the processes and results of disease, and to restore the largest possible measure of health, whatever may have been the departure from the normal.

The failures of therapeutics are very often referable to failures in diagnosis. It is not enough to name the disease or defect. We must know with some degree of exactness what organic and tissue processes are being enacted. Then and then only can the resources of medicine be brought to bear. No matter how perfect may be our control of bodily functions, unless by a minute diagnosis, we know what should be done, we cannot accomplish the aim and end of all therapeutic effort. Diagnosis is the key to medicine. Nothing short of the daily use of the microscope, the test tube, and the many other accessories to modern clinical diagnosis will answer the exactions of the present day therapeutics.

It is true that the medical profession is not and should not be satisfied with the present status of therapeutics. There is an infinity of things hoped for, but the emphasis should not be so laid upon the shortcomings and imperfections of our art as to obscure the public view of the splendid resources and powers of medicine in this very day and generation.

NEUROLOGISCHES CENTRALBLATT.

1. Myoclonic Twitchings in Progressive Paralysis. J. HERMANN.
2. The Scapular-Periosteal Reflex. STEINHAUSEN.
3. The Connection Between Dreams and Hallucinations. (Conclusion). A. KAZOWSKY.

1.—The patient, a man of 26, was admitted to the asylum with fully developed symptoms of general paralysis. In addition he had Romberg's symptom, loss of the patellar reflexes and an ataxic gait. Later he developed symptoms of distinct spasticity, that is to say, there were tonic contractions of the muscles, resembling those occurring in tetany. The condition lasted for about 6 weeks, and was then replaced in part by clonic contractions of the right arm, which then extended to the left arm, sometimes involving one, and sometimes a group of muscles. Later, groups of muscles were involved at once, and the lower extremities developed the same symptoms. The patient did not show any marked exacerbation of the mental

symptoms. The convulsions, however, became more and more severe the patient emaciated, and finally died. Numerous cysts were found in the subarachnoid spaces over both motor regions, and the ventricles of the brain were somewhat dilated. The left kidney was completely converted into a huge cyst. The condition resembled that of paramyoclonus multiplex. It does not appear reasonable to suppose that the conclusions were due to anything excepting the cerebral condition, and it is possible that they were the result of the cysts found over the motor regions. [J. S.]

2.—Steinhausen has studied the scapular-periosteal reflex in 300 healthy men of the garrison at Hanover. He concludes that it can only be elicited by striking upon the median border of the spine of the scapula in the position already designated by Haenel. The typical contraction involves the posterior fibres of the deltoid muscle, rarely the central portion, and still more rarely the biceps. Only when the contraction is very pronounced is there slight adduction and external rotation of the upper arm. The reflex invariably occurs in health. In about 76% of all cases it occurred easily, and in 11% it was somewhat exaggerated. It is not a muscular contraction because striking upon the body of the muscle does not produce it. It occasionally occurs with unequal force on the 2 sides. It is probably constant, because relaxation of the muscles of the shoulder is usual. [J. S.]

3.—Kazowsky regards the occurrence of a dream before a delusion as really a proof that the delusion is already present in latent form. He does not think that delusions can be produced directly as a result of suggestion by a dream occurring during sleep. In discussing his case he calls attention to the very marked disproportion between the cause—a reproof in the class-room—and the result—the murder, in the most brutal manner, of the teacher. He excludes, however, the idea that the case is one of moral imbecility. The boy had always been good-natured and had never injured anybody. On the other hand, he had been predisposed during his whole previous life, to explosions of temper, and particularly his reading had been of a nature to fill his mind with ideas of deeds of violence. The subsequent conduct of the patient, who went quietly to his home after the murder, and partook of the mid-day meal with his family, was sufficient proof that a period of relaxation, in which he was incapable of judging of his conduct, followed the outbreak. [J. S.]

2. A Case of Pulsation of a Tympanic Membrane Cicatrix. F. GROSSMANN.
3. The Value of a Vegetable Diet. ALBU.
4. The Symptomatology and Therapy of Appendicitis. KAREWSKI.
5. Concerning a New Electro-Therapeutic Procedure. P. RODARI.

1.—The author opposes the theory which assumes that pernicious anemia is a chronic infectious disease and he does not believe it justified to draw conclusions regarding the enterogenous origin of pernicious anemia from experiments performed on metabolism. The latter experiments above all are not tenable because we do not always know under what form of diet the disease occurs. Individual dispositions must be taken into consideration in discussing the enterogenous origin of pernicious anemia. Atrophy of the intestinal glands may be considered simply as a local toxic manifestation or as the consequence of the progressive anemia. He believes that many theories are exaggerated as many of the symptoms present in pernicious anemia frequently exist without grave changes in the blood. [M. R. D.]

2.—The author reports a case of pulsation of a tympanic membrane cicatrix occurring in a woman 33 years of age who had suffered from bilateral middle-ear disease since early childhood. Examination proved that the right tympanic membrane showed in addition to the normal cone of light, a second streak of light reflex which was pulsating synchronously with the cardiac systole and receded with the diastole. It was found that there was a compression of the right carotid artery from a goitre, a mitral insufficiency and a hypertrophy and dilatation of the left heart. [M.R.D.]

3.—To be concluded.

4.—To be concluded.

\$3.00 PER ANNUM

Infection with *Strongyloides Intestinalis*.—*Strongyloides intestinalis* is a small nematode which was first described, in 1876, by Normand, who discovered it in the stools of soldiers suffering from Cochin China diarrhea. Bevac, working at Normand's suggestion, named the parasite *Anguillula stercoralis*. Others workers subsequently found similar parasites in the stools of man and mammals, and a variety of names have, from time to time, been suggested for it. It seems to be conclusively shown, however, that *Anguillula stercoralis* and *Strongyloides intestinalis* are synonyms for the same parasite. On the other hand, there is no relation whatever between this worm and *Filaria sanguinis hominis*, as has been erroneously supposed. In the free-living generation the *Strongyloides* measures from 1 to 1.4 mm. in length and from .05 to .075 mm. in breadth. The cephalic extremity is rounded and pierced by the mouth, about which there are three or four papillae. Next to the mouth there is a vestibule, then comes the esophagus, which contains three chitinous teeth. Beyond the esophagus, the intestine extends to the anus, which is situated at the base of the tail. The female is larger than the male and usually more numerous than the latter sex. The vulva is situated on the right side of the body, a little below the middle, and leads into a double uterus, each horn of which ends in an ovary. The male parasite presents two cone-shaped and curved spicules at the base of the tail, which serve as the copulatory organ. The eggs are small, elliptical, and are usually segmented when laid. There are some slight anatomical differences between the free-living generation, the parasitic form and the larvae. While this parasite is frequently seen in France, Germany, Italy and Austria, the first case of the infection in North America was seen by Strong (Johns Hopkins Hospital Reports, Vol. X, Nos. 1-2, 1901), in 1896. The patient was a Bavarian, who had always lived in a small town until he came to the United States, eight years before. In this country he was a farmer for two years and worked as a tailor in Baltimore for six years. He complained of pain and swelling at the margin of the right ribs, and said that he had had from two to five stools daily

for three years. During the last portion of this period the stools contained blood. The swelling at the costal margin increased in size and a second tumor appeared in the back. These tumors were found to be abscesses that had reached the surface from the liver. The pus of these abscesses contained numerous actively motile specimens of amoeba dysenteriae, but was in other respects sterile. Microscopic examination of the stools showed a fair number of *Trichomonas intestinalis* and embryos of *Strongyloides intestinalis* in addition to the amoeba dysenteriae. The blood examination was not conclusive. The patient died of exhaustion, and at autopsy the parasitic form of the adult female *Strongyloides intestinalis* was found in the duodenum and jejunum; but not in the stomach, the bile ducts or the pancreatic duct. Strong is, at present, the Director of the Army Pathological Laboratory, at Manila, and since his residence in the Philippines he has seen four other cases of infection with this worm, one of which ended fatally. All of the patients suffered from an intermittent diarrhea often accompanied by gastro-intestinal disturbances. The stools contained many of the embryos, but no eggs and no adult parasites. The parasites have never been found in the blood. Cultivation of the embryos found in the stools has resulted in the development of both male and female adults of the free-living generation. The parasite is not harmless, because, in the Baltimore case, the eggs, the embryos and the worms themselves were found in the glands of Lieberkühn, in which situation they produced atrophy of the epithelium and round-celled infiltration from mechanical causes. At the same time, the worm is not regarded as particularly dangerous to man. We may expect to meet with more cases of this affection in North America, after the present free communication between this country and the tropics has continued several years.

The Surgical Treatment of Renal Tension.—This new invasion by the surgeon of a field that was, until quite recently, thought to be the exclusive property of the medical practitioner, marks another advance of surgical art. Like many other discoveries in medicine and surgery, the advantage to be

derived from renal incision in certain cases of congestion of this organ, was discovered, we might say, by accident. It was in 1896 that Sir Reginald Harrison first called attention to the fact that many cases of albuminuria supposed to be due to stone or some other removable cause, had been entirely cured by a simple exploratory incision made into the kidney substance. This fact caused Harrison to suggest tension as a cause of kidney disease and to recommend incision for its relief. We have before us this writer's latest communication on this interesting subject, being his address before the recent meeting of the Surgical Section of the British Medical Association, and we can commend most heartily its perusal to both medical men and surgeons. The author shows that increased renal tension is capable of producing those pathological conditions which we term Bright's disease. This condition is usually relieved by proper medical treatment, but there are cases in which it is held that an incision will relieve an acute nephritis which is so persistent in its progress as to be beyond the reach of drugs. The objection that an acute nephritis seldom goes on to suppuration and gangrene is met by the statement that these changes are anticipated by the death of the patient. Harrison refers to our treatment of other conditions where great tension is present, such as glaucoma and acute orchitis. He enumerates and illustrates with reports of cases, the various forms of renal inflammation which he thinks may be relieved by surgical intervention. These are: (1) Progressive signs of kidney deterioration, as shown by the persistence or increase of albumin when it should be diminishing or disappearing from the urine, as in the natural course of inflammatory disorders ending in resolution; (2) Suppression of urine or approaching this state; (3) Where a marked disturbance of the heart and circulatory apparatus arises in the course of inflammatory renal disorders.

One can hardly read this valuable paper without being impressed with its sound logic and the hope which the author holds out to many cases which are liable to result fatally.

The Advance in Renal Surgery.—The most important paper read before the German Surgical Congress in Berlin last April was Casper's "Progress of Renal Surgery." Before operating upon one kidney, Leopold Casper and Paul Friedrich Richter have devised a routine method of discovering, not only whether the other kidney is healthy or not, since man can live with a diseased kidney, but whether it is sufficiently healthy to be left to act alone. It is their practice to examine the urine withdrawn by simultaneous catheterization of both ureters, not

only for pus, albumen, casts, erythrocytes, micro-organisms, etc., but also for the total nitrogen, the height of the freezing point, and the amount of sugar excreted after an injection of phloridzin. A high freezing-point shows the functional ability of the kidney, while the appearance of sugar, approximately equal in quantity to the phloridzin injected, shows the chemical capability of the kidney. When both kidneys are normal, or both equally diseased, the results of the examinations of the urine will be similar. When all the results from the urine of one kidney are low or negative, there remains no doubt that the kidney on that side is seriously affected; when the results from the urine of the other kidney are approximately normal, the diseased kidney should at once be removed. Ten such case-histories are reported by Casper in the *Archiv für klinische Chirurgie* (1901, Volume 64, No. 2). Operation in these cases (seven nephrectomies, two nephrotomies, and one pyelotomy) was successfully performed. Casper adds the details of four more cases, in two of which both kidneys were found diseased. Operation was, therefore, not performed. Autopsy, held later, confirmed the diagnoses. In the other two cases, the other kidney was found to be temporarily insufficient and operation again was not done. With the aid of these excellent new methods, in addition to those already in use, we may look forward to a more exact diagnosis of renal disease and a more certain prognosis from renal operations.

The Utility of Cryoscopy.—In our issue of June 1, of the current year, there appeared an editorial upon this subject which was partly an historical résumé and dealt also with some of the results which cryoscopy promises. In our issue of June 29, 1901, we printed an original contribution: "Upon the Freezing-Point of Urine; Its Determination and the Inferences Which May be Drawn from It" by Dr. J. H. Huddleston, of New York. There are a number of points of practical value in Dr. Huddleston's paper which deserve mention. He has carefully studied the subject of cryoscopy and in addition to that he has done a considerable amount of clinical work in this field and furnishes us with his method in detail. Of especial interest are the conclusions which he draws as to the uses of urinary cryoscopy. He calls attention to its pre-eminence as a test of function quite independent of structure. In cases of uncomplicated diseases of the heart the new method has won high esteem. Koranyi places especial value upon the findings of cryoscopy alone and from the results obtained he is able to direct treatment of the cardiac condition from the indications as to whether the circulation in the kidney is hindered in the slightest degree, and from the state

of arterial tension which is also revealed. It is interesting to learn that certain ratios obtained in uncomplicated diseases of the kidney may show the existence of a glomerular nephritis as distinguished from the tubular, a distinction, as Huddleston remarks, which has hitherto been hardly possible. In cases of combined heart and kidney disease the value of certain ratios points to the organ chiefly at fault, and in cases of effusion into a serous cavity, we are enabled by cryoscopy to learn whether absorption or exudation is going on. This deduction is comparable to that one long ago made known as to the increase or decrease of chlorine in the urine. It is evident that while this method is distinctly to be followed out in the laboratory and requires time and skill, as our facts are accumulated, much will be learned. It especially represents a notable advance in the application of quantitative physico-chemical methods to clinical work.

Havana's Best Record.—Major W. C. Gorgas, Chief Sanitary Officer for Havana, states in his report for July that the best record ever made for that month in the matter of yellow fever was made this year. Five hundred and thirty-seven deaths from all causes occurred in the city during last July, which was the smallest number recorded since 1889 with the single exception of the year 1900. As Havana has a population of 257,777, the death rate for July was at the rate of 24.99 per 1,000. This compares favorably with many more northern cities. In fact, for the week ending July 6 New York had a death rate of 41.86 and Pittsburg had one of 34.03; but these and other northern cities were suffering at that time from the effect of the abnormal heat.

Only four cases of yellow fever, with one death, occurred in Havana in July. Two of these cases occurred in children, and were of a type of the disease which is known locally as "Borras," and which is not recognized by the physicians in Havana as being yellow fever. Of the identity of the disease, however, Dr. Gorgas says there is no doubt.

In 1897 there were 168 deaths from yellow fever in Havana in July; in 1899 there were only two deaths; in 1901 there was one but one death. This change is coincident with the occupation and cleaning of Havana by the United States Government. Major Gorgas says that the chief warfare now in Cuba is against the infected mosquitoes. He evidently accepts it as settled that the mosquito is the agent of infection.

Medical Education in China.—It is difficult for us in the midst of our great Western civilization to appreciate the fact that an immense empire like China, with an ancient and in some respects highly developed civilization of its own, is practically with-

out hospitals, medical colleges or any system of practice approaching a true science of medicine. In a recent number of the *China Medical Missionary Journal*, Dr. H. T. Whitney describes briefly the situation in China and its needs. He says that there are no Chinese hospitals, no Chinese medical colleges, no Chinese physicians proper, and no Chinese medical science. It evidently remains for the pioneers of Western civilization to introduce this science with all its necessary appurtenances into the Celestial Empire. This is a vast but most interesting problem. Dr. Whitney thinks there has never been a more opportune time than the present for extending the medical work already done. The Boxer movement of last year was but a temporary hindrance. Thus far the pioneers of Western medicine have been largely the missionaries. They have seized the opportunity to make medicine the handmaiden of religion, and it is doubtless true that they have done some good in this way. But what Dr. Whitney, with wise forethought, perceives and emphasizes, is that China must have her own medical colleges and schools as well as her own scientific medicine. The Japanese have already taken great strides in this direction, and some of their medical scientists have contributed substantially to medical knowledge. In China, on the contrary, everything remains to be done. The few missionary schools and hospitals are thus far mere nuclei. They are in every sense exotic, and while doubtless they are and will continue to be the centres of medical science, they cannot be said to have taken root until they have interested the Chinese people and government in this problem of medical education. In other words, the natives themselves must be trained and educated as physicians; the hospitals and medical schools must be essentially Chinese, although doubtless they will require to be under Western tutelage for some years to come.

We are glad to note that there is a plan for the establishment of a native medical college in Nanking or Hankow. We consider this whole subject of transcendent interest and importance. When we consider the vast population of China and its needs, no words are wanted to paint the extent of the field and its importance for future cultivation. We extend to this movement our hearty congratulations.

In this connection we might say that we believe that while much is owing to the missionaries for the introduction of medicine into China, it is nevertheless better that medical science should take such a root in that country that in a sense it will propagate itself. In other words, we believe it should be secularized, as it is in all civilized countries. While the conditions in China have evidently been such as to require the propaganda of the missionaries in order

to introduce medical science into that country, it will nevertheless be better in the end, and more wholesome, for the more advanced and educated Chinese to see for themselves that medicine is to be cultivated for itself.

Women as Scientists.—The problem whether women are fitted to succeed in scientific pursuits seems to have been solved satisfactorily by the late Eleanor Omerod. As a scientist Miss Omerod gained distinction in entomology. For years past she had been an authority in that department especially of entomology which relates to agriculture. She studied insects from the economic standpoint—that is, for their injurious effects upon agriculture, just as now we are beginning to study them more closely for their injurious effects upon human health. Hence Miss Omerod was a pioneer in a field which lies contiguous to that of human pathology. Her career was most interesting and instructive. From *Harper's Weekly* we learn that in early life she began to study insects on her father's country place in Gloucestershire. She studied their ravages in the fields and orchards, and the work became a life work. She contributed to the Royal Horticultural Society, and became entomologist to the Royal Agricultural Society. For twenty-four years she sent out an annual report of her work. Her fame spread abroad, and she was consulted by suffering agriculturists in all parts of the world. In recognition of her researches she received many medals, and last year she received (a rare thing in Britain) the degree of Doctor of Laws from the University of Edinburgh. Her work was untiring and unselfish, for it seems to have been done for the love of it and not for gain. At the age of seventy-three she died, having bequeathed to science the record of a great work, and to her sex the distinction of a fine career.

No Quarrel with the Medical Profession.—Mr. James M. Brown announces in our columns to-day that the American Humane Association has no quarrel with the medical profession. As Mr. Brown is President of that Association he ought to be familiar with the objects of its animosity. We thank him for helping us to that expression. A quarrel with the medical profession for its work in the amelioration of human suffering would not redound to the credit of Mr. James M. Brown's Association in the eyes of the public, and he evidently knows it. There is in the expression the suggestion of a fear that Mr. James M. Brown's Association may cut a sorry figure in its senseless and mendacious tirade against medical science. As for the medical profession, it is amply able to account for itself and its work. It does not hide its light under a bushel of mock hu-

mility or of ambiguous phraseology. It indulges in no spurious benevolence. It has a mission to perform in this world, and it will perform it. It does not sacrifice women and children in any hospital in the land (as millions of mothers and children will testify), and the man who utters that libel against it is condemned out of the mouths of babes and of sucklings. In the meantime Mr. James M. Brown would have done better to answer Dr. Keen's arguments rather than merely to wish that distinguished surgeon God-speed on his distant journey—a wish which no doubt came straight from Mr. Brown's heart. In the opinion of the President of Mr. James M. Brown's Association it is probable that Dr. Keen can not go too far away.

To Fly or Not to Fly.—We learn from the daily press that Monsieur Santos-Dumont has solved the problem of aerial navigation, and the statement is reiterated with more confidence than ever before. Now we do not wish to detract in the least from the great service that Monsieur Dumont has rendered the human race, but we might, in passing, call attention to the fact that the solution of the problem of aerial navigation was very nearly reached some years ago by an American, Professor Langley, and that he was able to construct a machine that flew very well without the aid of balloons or other artificial support; the only difficulty being to obtain an engine that, with the requisite lightness, would continue working for a sufficiently long time, and this, of course, is only a question of time.

In the early days of aeronautics, an effort was made to imitate the flight of birds. In our later days we have abandoned this entirely, and the modern plan is either a modification of the kite, pulled along by a propeller instead of a string, or a balloon pushed along by the same means. It might be urged that an effort should be made to imitate nature, but when we think how slightly our modern steam-ships imitate the mechanism by which fishes move through the water, we can readily believe that our flying-machines will not necessarily closely resemble birds. And there is a good reason for this; because persistent rotation never occurs among living creatures, and it is the most common and easily produced mechanical motion.

There is one feature of the bird's flight that will perhaps be very closely imitated in our future machinery; that is, soaring. This, of course, is practically only an application of the kite idea, with gravity instead of a string. The only question is whether it will pay. Whether, that is, it is more desirable to imitate the condor with its huge wings spread and occasionally flapping, or the loon, with its large body and small wings working persist-

ently; or, if we choose to find another illustration, we might compare the honey-bee and the dragon-fly.

Of course, the question for us is, what effect this new sport or occupation will have upon health. Naturally, the ordinary injuries will not differ from those produced in other ways, but is it not possible that mountain sickness will become a common complaint, and that as vigorous and perhaps as unsuccessful efforts will be made to combat it, as have been made to combat sea-sickness? Physicians may also be called upon to devise methods of overcoming some of the other unpleasant results of high altitudes, and it may be that a new class of maladies may arise as a result of some particular strain or effort analogous in their ways to railway spine, and other manifestations of hysteria.

Even as it is an "ill wind that blows nobody any good," so it is a very good wind that profits many people, and perhaps the breeze caused by Monsieur Dumont's propeller will redound to the advantage of many trades, not excepting our own.

The Role of the Lymph-glands in the Infectious Diseases.—In a thorough review of this subject in the (*Bulletin Medical*, 1901, No. 39) Dr. Courtois-Suffit states that the lymph-glands physically, chemically, and anatomically represents differentiated organs for the protection of the organism against microbes and their toxins. According to the malignancy of the invading infection, the microbe may disappear before reaching the nearest lymph-gland; it may reach the nearest gland only; it may reach a far off gland; or it may quickly reach the blood *via* the thoracic duct. It is most common, however, for the invading micro-organism to remain in the nearest lymph-gland, which enlarges. Polynuclear leucocytes arrive, by the blood channels, and the lymph cells become detached. Far off glands enlarge when the toxin or the microbe reaches them. These processes are most frequent in childhood, and may persist. The reaction may be so marked as to cause a general disturbance, glandular fever, or bronchial adenopathy. In adults the lymph-glands become sclerosed, and with old age they atrophy. These glands are then much less able to protect the organism. [M. O.]

Tuberculous Meningitis.—(*Le Bulletin Medical*, 1901, No. 38) publishes an article by Professor Raymond upon tuberculous meningitis, localized in plates. This is generally found in adults, the plates lying near the Rolandic region. The ordinary symptoms of basal meningitis are absent, while those due to irritation of the cortical motor centers predominate. Yet some cases are only found post-mortem. It may be over the paracentral lobule, causing ascending symptoms; over Broca's convolution or the island of Reil, causing descending symptoms; or over the ascending frontal convolution, causing radiating symptoms. Motor aphasia, paralysis, convulsions, epileptic or tetanic, with or without pain, contractures, etc. are the main symptoms. The paralysis is generally well limited, and occurs first in one extremity. Sensation is affected before or with the appearance of the motor symptoms. The tache cérébrale is always absent, as are vomiting, constipation, scaphoid abdomen, etc. It occurs suddenly, one paralysis succeeding another; or an epileptic attack with aphasia is first noted. These rapidly grow worse, and death occurs. It is seen in people with phthisis, and is easily differentiated from diffuse basal meningitis, syphilis, or tumors. In children it may be mistaken for acute anterior poliomyelitis. Raymond suggests removal of the plate just as soon as a diagnosis of localized tuberculous meningitis in plates has been made. [M. O.]

Reviews.

Proceedings of the Association of Military Surgeons of the United States. Vol. IX. 1900. Chicago. R. R. Donnelly & Sons Co. 1901.

The Association of Military Surgeons of the United States is made up of medical men of the regular army and of the National Guard. It is interesting to note that for 1900-1, nearly all the officers and members of the executive committee belonged to the National Guard. This speaks highly for the courtesy of the regular army, since the subject matter of this volume has been contributed in the main by the men of the established service.

Standish contributes a paper upon the standard of vision required of the enlisted men, and places this at 20-XX in the right eye and 20-XL in the left eye, as more than sufficient for practical service. Even if the standard of vision were placed lower the service would not suffer, and many otherwise eligible men would not be rejected. It certainly strikes the practical observer that since the time of hand-to-hand conflicts has passed by, a defective vision which can be corrected by glasses should prove no impediment to military service.

Huddleston weighs the value of the Schumberg method of purification of water for military purposes. It will be remembered that Schumberg's method is based on the disinfecting power of bromine. He prepared tablets of this, one of which was sufficient to sterilize one litre of water. Huddleston found that the method is sufficiently rapid and practicable.

There is an interesting contribution from Kemp upon field work in the Philippines. Newgarden describes an emergency litter or cot. Shoemaker describes the treatment of sick and wounded soldiers in Philadelphia after the Spanish-American War. Borden's paper upon military surgery is an admirable résumé of the experience gained in recent wars and of the modifications in treatments suggested by such experience. Lagarde reports a number of wounds by jacketed projectiles, and particularly calls attention to the absence of remote effects except such as relate to the anatomical structures involved. Borden, as a result of a study of the mortality of war-wounds, notes that of every one hundred men struck by the new bullet, as many will be killed outright as with the old, but that many more of the wounded will recover. He also notes that recovery will be rapid in a great majority of cases, and it may be assumed that two-thirds of the wounded will be back in the fighting line in three weeks. Godfrey describes a new method of controlling hemorrhage in the arm and axilla. It consists in raising the arm upward and inward as far as possible. When the limit of the motion is reached no pulse can be felt in the axilla or below it. Kean suggests a tropical ration. The requirements of such a dietary as opposed to one suited to colder climates are: (a) less fats and more carbohydrates, (b) less stimulating proteid in the form of meat, and (c) a greater variety of diet, both of meats and carbohydrates in the form of fresh vegetables and fruits. From this general formula he deduces what seems to be a very admirable working one. Munson contributes an admirable paper on the same subject. Pope suggests a very complete plan for the organization of a medical department for war service. Hoff writes briefly and very clearly concerning the ambulance company of the first Division, Third Corps. Kulp makes some excellent suggestions with regard to identification and routine correspondence. Bradley writes entertainingly upon the ski and its use for military purposes in the Yellowstone National Park. An improved closet for camp latrines is described by Godfrey. Munson suggests a new method of waterproofing military cloth. There are also other contributions upon very practical matters connected with military service well worth reading.

It will be seen that this volume is one of great value not only to the army surgeon, but to every physician who wishes to be well informed upon the advances in his profession. [E. M.]

International Clinics, a Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and Other Topics of Interest to Students and Practitioners, by Leading Members of the Medical Profession Throughout the World. Philadelphia. J. P. Lippincott Company. Edited by Henry W. Cattell M. D. Philadelphia.

It is with general satisfaction that we review this number of the *International Clinics*, for the volume reaches a degree of excellence rarely attained in works of similar nature. We call particular attention to the beauty of the illustrations, which reach a high degree of perfection, as well as to the excellent typography which always characterizes the works of these publishers. It is somewhat difficult within the scope of this review to attempt to detail as we would wish, the separate articles, all from the pens of well-known writers and very many from conceded authorities upon their respective subjects. Three valuable contributions are devoted to the subject of locomotor ataxia and of especial interest are the Lectures upon Movement Therapy for Locomotor Ataxia, by H. S. Frenkel, of Melden, Switzerland. Despite the myriad methods of treatment which are advocated in this malady, a description of movement therapy, while its range of applicability is confined strictly to lessening the inco-ordination, will be read with interest and profit. Another neurological contribution, Some Suggestions as to the Mechanism of Mental Operations, by Prof. Santiago Ramon Y. Cajal, of Madrid, furnishes us with the opinion of a famous neurologist upon a subject of rare interest, yet of extremely difficult exposition. Prof. James Tyson has treated the subject of Croupous Pneumonia with his usual fulness and clearness. We mention especially the valuable paper by Prof. T. H. Tuffier, of Paris, on Surgical Analgesia by Injections of Cocaine into the Spinal Column, as well as that by A. Doleris, of the same city, upon the Oxytocic Effect of the Lumbar Injection of Cocaine. Particularly to Induce Labor. A. Broca has discussed the Conservative Treatment of Appendicitis, and gives us a judicious exposition of what medical treatment will do for this condition. J. B. Deaver, of this city, has also contributed a lecture, Litholapaxy, Osteomyelitis, Incision of the Upper Maxilla, Complete Rectal Fistula, and other cases treated at a clinic in the German Hospital. J. F. Schamberg treats of smallpox with particular reference to the prevalent epidemic. This article is one of practical value, and is accompanied by a number of graphic illustrations of the condition. J. D. Fowler, of London, has discussed the Diagnosis and Prognosis of Some Forms of Blood Disease in Infancy, a subject of decided importance and bearing. Indeed, a careful reading of this volume fills us with admiration for its decided excellence and breadth of subject matter. We observe that two other Philadelphians are among its contributors, W. T. Shoemaker who has studied the External Ocular Signs Found in States of Unconsciousness, and Dr. W. A. N. Dorland, who furnishes the pronunciation and definition of a number of the newer medical words, a subject which the breadth of our vocabulary demands must be expanded constantly in order to meet the growing needs of medical science. [T. L. C.]

What Should be Considered a Tuberculin-reaction in cattle.—N. F. Mischkin, in a paper read before the Section of Bacteriology of the Imperial Society of Natural Science, Anthropology and Ethnography (*Russki Archiv Patologii, Klinicheskoi Meditsiny i Bakteriologii*, March, 1901), gave the results of the application of the tuberculin test in 300 heads of cattle. All the animals, showing a maximum temperature of 40°C. proved tuberculous. Out of 9 showing a maximum temperature of 39.9°C., 8 proved tuberculous, out of 6 with a maximum temperature of 39.8°C. 5 proved tuberculous, out of 3 with a temperature of 39.7°C. only 1 proved tuberculous. Five animals with a maximum temperature of 39.6°C. proved to be perfectly healthy. In two cases of undoubted tuberculosis the reaction was altogether absent. The author, therefore, considers those animals free from tuberculosis in which the maximum temperature elevation following the injection does not exceed 39.6°C. [A. R.]

Correspondence.

FOUR CASES OF ACUTE HEMORRHAGIC MENINGOMYELITIS IN COCKER SPANIELS.

By PHILIP KING BROWN, M. D., San Francisco.

From the Pathological Laboratory of the Cooper Medical College.

To the Editor of the *Philadelphia Medical Journal*:

In the fall of 1898 there occurred in San Francisco within a few weeks a number of cases of an acute flaccid paralysis in dogs, four of which cases, through the favor of Dr. K. O. Steers, of the Veterinary Department of the University of California, I saw during life at his hospital, and after close observation clinically, I was permitted to kill the animals and examine them immediately.

All of my cases were in unrelated Cocker spaniels from different parts of town, or from neighboring towns. Paralysis of the hind legs was the first symptom noted in each case, and there were loss of appetite, incontinence of urine, constipation, tenderness along the spine, and fever. The paralysis soon became complete in the affected parts and appeared to be progressively ascending. No convulsions were noted in any case.

The onset of the trouble was sudden in all but the last case, and the actual paralysis was acute there, too. As nearly as could be ascertained, all had fever, two had marked fever (ascertained per rectum), before they were destroyed—in the last case, due probably to the complicating pneumonia. No etiological factors were common to any two cases. It has been said that there has been a great deal of inbreeding here among high-class dogs, but none of these dogs were closely related. In all, the trouble began in the lumbar cord and extended upward, and in two the cervical cord was extensively involved, particularly in regard to the hemorrhage. In all cases the softening was far more extensive than indicated by the hemorrhage.

At post mortems, cultures and smears were made in all but one case, and no bacteria were found, nor were they found in sections.

There were no lesions of any other organs except a pneumonia in one case, and that was clinically secondary to the involvement of the cervical cord. The lesions found anatomically were the same in all four dogs, differing only in duration and extent, and consisted largely of hemorrhages into the grey and white substance of the cord, the pia mater, and the loose connective tissue outside the dura mater. In the latter position some of the clots formed after the hemorrhage showed signs of beginning organization. In addition to the hemorrhages, there were extensive necroses and degenerations in the spinal cord which did not show any relation in size and distribution to the hemorrhagic process.

In a few spots it was possible to see some cellular infiltration. The degenerative processes affected the white and gray matter indiscriminately, and in many places extended over the whole cross section of the cord. There was no relation apparent between them and the distribution of the blood vessels. No thrombi or arterial changes were found in any case.

No evidence of an injury to any of the dogs either in the vertebral canal or externally was discovered. No bone changes were present in the vertebra which could have caused compression, such as was found by Dexter in dogs in the cases reported by him in Lubarsch and Ostertag's *Ergebnisse*, 1898.

The cases are held by us to be hemorrhagic meningomyelitis, and not hematomyelia or primary hemorrhage with secondary myelitis, because inflammatory lesions are present, although not extensive, and in all cases, of acute hematomyelia described, authors refer to the lack of microscopic evidences of such inflammatory changes. More than this, the hemorrhages cannot explain the entire process because the degenerative changes and necroses do not follow the hemorrhages, nor are there any vascular lesions to explain the necrosis and degeneration.

The peripheral nerves were not examined in any case, but the fact that the spinal roots were either not involved or only secondarily involved in the process, tends to prove

that the spinal changes did not follow ascending neuritis, a sequence to which Leyden and Marinesco have called special attention, and which Homen has produced experimentally in animals by injection of streptococci into the peripheral nerves.

HUMAN VIVISECTION.

By JAMES M. BROWN, President of the American Humane Association.

To the Editor of the *Philadelphia Medical Journal*:

I have read the communication of Dr. Keen, published in your issue of August 10th, and already applications have been made by members of the medical profession for literature concerning the subject of the controversy—Human Vivisection.

As The American Humane Association considers this matter one of vital importance, its Executive Committee has, after amendment and revision, just printed that review of Dr. Keen's letter upon which he, in his last communication, comments; and in order to do him justice the Association has added his first letter, which he has called "The Misstatements of Anti-Vivisectionists." These two (2) documents in one pamphlet can be secured gratis by any physician in the United States who will send his professional card to "The Special Committee," Post-office Box 215, Providence, Rhode Island.

For those medical men who carefully read this pamphlet, it would seem to me that Dr. Keen's latest letter will need no reply.

If your space would permit, there could be pointed out in this document some very serious misquotations, leading him to misstatements and comments which ordinarily would be without excuse.

I prefer, however, to join with his many friends in speeding Dr. Keen in his journey around the world, and wishing him a pleasant voyage and a safe return; to leave his misconceptions and mistakes to his own sober judgment, and the rectification that time will surely bring.

This association can have no quarrel with the medical profession. It believes, rather, that in condemning and opposing the use of human beings, chiefly women and children for experiments, dangerous to life and health, it has the sympathy of the great majority of the physicians of the United States.

Nothing can so surely and utterly destroy all confidence in the personele of the medical profession, and in the security of our hospitals and asylums, as a well-founded impression that every patient, young or old, strong or feeble, high or low, rich or poor, is not absolutely secure in all of his personal rights.

He who, in the pretended interests of science, consciously aids in the destruction of this confidence or security, is, in my judgment, little less than an enemy of his race.

Myxedema.—(*Le Presse Medicale*, 1901, No. 39) publishes a clinical lecture at the Beaujon Hospital by Professor Debove, upon myxedema. He presented two cases after reviewing the whole subject of the thyroid gland, defining myxedema as the condition observed when the action of the thyroid is either suppressed or diminished, a condition found with absence, atrophy, or alteration of the gland. The first case was one of congenital myxedema in a man of 20, both of whose parents were chronic alcoholics. His mother showed some signs of myxedema, also, and syphilis was suspected. At the age of 14, his development stopped. Myxedema generally develops at puberty, and is most frequent in women. He drinks excessively, also, now. His expression, infantilism, slowness of movement and intellect make the diagnosis. He is taking thyroid extract. Debove also presented a case of latent myxedema, a young man with mitral insufficiency and emphysema following rheumatism. He is small, with the face of an old woman, and abundant hair. His skin is smooth and glossy. He has never developed sexually, and his voice is distinctly feminine. No thyroid gland is palpable. His intellect is quite deficient. He is also tuberculous. Debove closed by stating that if one sought for latent or abortive cases of myxedema, the affection would be found much more frequent than one should imagine. [M. O.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Vital Statistics of Philadelphia.—Dr. Henry Leffman, at one time Port Officer of the Bureau of Health, as well as microscopist and food inspector for the Pennsylvania State Board of Agriculture, and now Pathological Chemist at the Jefferson Medical College Hospital, and Professor of Chemistry at the Women's Medical College, at Philadelphia, has always made a careful study of the sanitary conditions of cities. In a recent interview he is quoted as having made the following statement relative to the vital statistics of Philadelphia: "In many ways vital statistics are misleading, not so much in what they say as in what they do not say. They merely report so many deaths per annum to each one hundred or one hundred thousand of population. It must be clear to any one at first glance that this cannot be a proper basis from which to reach conclusions in regard to the health of a city. To be absolutely correct the statistics should show the cause of death in every case. Death from accident or natural causes must not count against the hygienic condition of a city. With our vast system of electric and steam surface roads it is possible that the deaths in Philadelphia by accident from this source exceed those of any other city, and especially the city of New York, with its general elevated systems. Again, in most of the cities, the machinery for swelling population is very active, while the reporting of deaths is careless and inaccurate. In some cities the laws requiring the report of every death and of its cause are not at all rigidly enforced. Possibly there is a tendency to overestimate the population and undercount the deaths. As to Philadelphia, I believe the population has never been exaggerated, and that the reports of mortality are probably more nearly correct than in any other large city. For several reasons it is not surprising that Chicago shows a much lower apparent death rate than Philadelphia. A large portion of the population is composed of young adults attracted there because it is the great metropolis of Western activity, and among this element the death rate is low. Again, Chicago has a way of estimating its population which is almost peculiar to itself. It is largely speculative, and it is safe to say the speculation is affected by Chicago's vaulting ambition. Doubtless the deaths are also largely reported. That would be natural in such conditions. Therefore, it will be realized that statistics, such as those furnished by Chicago and some other cities to the census people, must be taken with many grains of salt. The only intelligent method by which we can make a comparison of the hygienic condition of our great cities is to take the reports, not of the total number of deaths, but of the deaths from diseases, and especially those diseases which are due to unsanitary conditions or to ineffective machinery for the prevention of the spread of contagious diseases. But even with such a comparison the result must be misleading so long as populations are overestimated and deaths not fully reported. If a faithful report of illness could be made it would be vastly more valuable than reports of mortality. The latter are often almost no true indication of the number who are ill from a specified disease. I have known a whole region of Philadelphia to be afflicted with typhoid of a mild type with but few deaths compared to the large number of sufferers. A full, faithful, honest weekly report of every case of illness which requires the attention of a doctor would be of incalculable value in connection with efforts to stamp out and prevent disease.

Dr. Robert J. Black, the mayor of McKeesport, who has been considerably quoted in connection with the strike, is a practicing physician, and a graduate of the Baltimore College of Physicians and Surgeons.

Vital Statistics of Philadelphia for the week ending August 24, 1901:

Total mortality	491	Cases.	Deaths.
Inflammation of the appendix	4		
bladder 1, brain 20, bronchi 3,			
heart 3, kidneys 18, lungs 31, per-			
icardium 1, peritoneum 4, pleura			
2, stomach and bowels 45	132		
Marasmus 37, inanition 29, debil-			
ity 6	72		

	Cases.	Deaths
Tuberculosis of the lungs		47
Apoplexy 8, paralysis 1		19
Heart-disease of 21, fatty degenera- tion of 2		23
Uremia 15, Bright's disease 7, dia- betes 4		26
Carcinoma of the breast 1, jaw 1, stomach 4, uterus 2		8
Convulsions		11
Diphtheria	35	6
Brain-softening of		1
Typhoid fever	126	10
Old age		7
Scarlet fever	40	3
Abcess, liver 1, lungs 1, alcoholism 2, asthma 2, atheroma 1, burns and scalds 4, carbuncle 1, casual- ties 11, cerebro-spinal meningitis 1, child birth 2, cholera infantum 34, cholera morbus 1, cirrhosis of the liver 4, consumption of the bowels 1, croup, membranous 1, cyanosis 1, diarrhea 3, drowned 7, dysentery 7, epilepsy 1, fever, malarial 1, gangrene, senile 1, homicide 1, jaundice 1, locomotor ataxia 1, measles 1, obstruction of the bowels 2, septicemia 6, smallpox 1, sore mouth 2, suffo- cation 2, suicide 1, sunstroke 3, syphilis 1, teething 2, tumor, stomach 1, uterus 2, unknown cor- oner case 1, whooping cough 10..		126

NEW JERSEY.

The Charges at the Trenton Insane Asylum.—The investigation into the management of the Trenton Insane Asylum seems to have assumed a sensational aspect since Dr. William F. Jones has preferred charges that an inmate had been ill-treated by an attendant about a year ago, resulting in his death. As the matter is still under investigation, it is as yet difficult to say how far these charges will be substantiated. In addition there is also an inquiry regarding the food, and a committee which recently investigated this subject agreed that no fault could be found with the edibles.

United States Laboratory for Sandy Hook.—A Government laboratory is to be built at Sandy Hook. It will cost \$10,000, and will be used by ordnance officers and experts in experimenting with explosives.

Tuberculosis Declared Contagious.—The Jersey City Board of Health has notified all physicians to report every case of tuberculosis as a contagious disease.

NEW YORK.

North Hudson Hospital.—Dr. John T. Luck and Dr. Benson have been added to the medical staff of the North Hudson Hospital.

Brooklyn Eye and Ear Hospital.—The recent annual report of this institution shows that during the past year there were treated 14,883 cases. Of these 9,199 were diseases of the eye; of the ear, 3,110; of the throat, nose and skin, 2,227; of the nervous system, 247. The total year's income was \$16,000. The erection of a new building is under contemplation.

A Physician Seriously Injured.—Dr. J. C. Kennedy, of Brooklyn, surgeon-in-chief of the consulting staff of St. Catharine's Hospital, was seriously injured on August 17th in attempting to save the life of his carriage boy, while the latter was being run away with in the doctor's carriage.

A Life Insurance Precedent.—It is stated that in a city in the northern part of the State of New York a woman, having been compulsorily secluded for about six weeks on account of smallpox, notified the Board of Health that her policy of life insurance was likely to lapse, inasmuch as her detention was preventing her from getting the money necessary for the payment of a premium, and that the board paid the premium, holding that if the policy lapsed and the woman died there would be a case against the city.

WESTERN STATES.

Appointment.—Dr. Eliza H. Root has been appointed Dean of the Northwestern University Women's Medical School.

Dr. H. Ehrenfest, formerly Assistant in Professor Schauta's Clinic in Vienna, has been appointed Consulting Gynecologist to the City Hospital, St. Louis, Missouri.

Dr. Reuben Peterson succeeds Dr. J. N. Martin as Professor of Obstetrics and Gynecology at the University of Michigan.

Northwestern University Medical School.—Dr. A. P. Ohlmacher has been appointed Professor of Pathology in the Northwestern University Medical School (Chicago Medical College.) Dr. Ohlmacher has been connected with the Pathological Laboratory of the Ohio Hospital for Epileptics at Gallipolis, Ohio, and will for the time continue the direction of the Laboratory.

The Mississippi Valley Medical Association.—The twenty-seventh annual meeting will be held in Put-In-Bay, Ohio, on Thursday, Friday, and Saturday, September 12th, 13th, and 14th, under the presidency of Dr. Albert H. Cordier, of Kansas City, Missouri. In addition to the president's address, the preliminary programme contains the following titles: Address in Medicine, by Dr. Frank Billings, of Chicago; Address in Surgery, by Reginald H. Sayre, of New York.

Increased Mortality in Indiana.—The Bulletin of the State Board of Health for the month of July, just issued, shows that there were 3,162 deaths in the State during the month, an increase of 919 over the number for the corresponding month last year. The rate for the month was 14.8 against 13.1 for July last year. Of children under five years, 1,005 died, including 698 deaths of children under one year. Of the total number of deaths, 1,259 took place in cities.

Scarlet Fever in Chicago.—The spread of scarlet fever in Rogers Park continues. Twenty-eight cases have been reported up to the present time.

The Medical Society of the Missouri Valley will hold its fourteenth annual meeting in St. Joseph on Thursday, September 19, and Eureka Springs, September 20 and 21.

SOUTHERN STATES.

Death of Dr. Robert Barnwell Rhett.—Dr. Robert Barnwell Rhett died at St. Francis Xavier Hospital, Charleston, August 7, from typhoid fever, aged 47 years. He was Dean of the Charleston Medical School, and a member of the American Medical Association. He was graduated from the Medical College of the State of South Carolina, Charleston, 1879.

Texas State Association of Health Officers.—At the meeting of the Texas State Association held in Dallas, August 8, the following officers were elected for the ensuing year: President, Dr. Isaac J. Jones, Austin; vice-president, Dr. William H. Blythe, Mt. Pleasant, and secretary and treasurer, Dr. James E. Wilson, Dallas. The next meeting will be held in Austin.

Condition of Brain May be Shown by Photograph.—We are indebted to the *Journal of the American Medical Association* for the announcement that the testimony of the experts in the homicide case of Monson vs. State of Texas, showed that there was a blow on the left side of the head of the deceased which fractured the skull for an inch or so, and that on the opposite side of the head and on the brain was clotted blood. In connection with the expert testimony, the state was permitted to introduce before the jury a photograph of the head of the deceased, showing the condition of the brain after the removal of the skull at the autopsy, which photograph, the expert witnesses stated, correctly represented the condition which they purported to show. This was objected to. But the Court of Criminal Appeals of Texas does not consider that it was error. It says that it does not believe that it was calculated to unjustly prejudice the rights of the accused before the jury, while, under the authorities, it believes this character of evidence is admissible.

Charges of Discourtesy Investigated.—The Board of the Western State Hospital for the Insane, at Staunton, Va., have been investigating charges of discourtesy to Dr. Chertsey Hopkins, the woman physician in the hospital. It was found on careful examination that the charges were

really due to a lack of harmony and social and personal good feeling among the officials.

Polluted Water at Lewes, Del.—Physicians have discovered that the drinking water used in the fish oil factories at Lewes, Del., is full of typhoid fever germs, and it has caused illness among fishermen.

Physicians of Virginia.—More than a hundred new doctors have recently been licensed to practice medicine in Virginia.

CANADA.

A Death Through Christian Science Negligence occurred in Toronto within the past two weeks; and as an evidence of the healthy state of the public mind towards the peculiar doctrines of these people, the coroner's jury returned a verdict worthy of more than an ordinary notice: "That the said—boy—came to his death on Tuesday, August 13th, from diphtheria, and we find that . . . the father of the deceased showed culpable criminal negligence in not providing medical assistance, medicine, nursing and comforts, and that . . . the Christian Science demonstrator, was an accessory after the fact, inasmuch as he undertook to advise and treat a dangerous contagious disease, which he admitted he was totally ignorant of. The teaching of the sect known as the Christian Scientists, as brought out in the evidence, is a danger to the community, and the jury would recommend that the law should make it a criminal offence for a demonstrator of this peculiar sect to attend or treat a case which is not being attended by a duly qualified practitioner."

The McGill Medical Faculty owing to the alterations which are now going on has decided to postpone the sessional opening until the 1st of October, instead of the 13th of September, as ordinarily, as the buildings cannot be got ready for the reception of students before that date. Great efforts are now being put forth to have the faculty rooms, the library and the several laboratories finished in time for the approaching visit of the Duke of York, on which occasion McGill will certainly give a good account of herself. It is hoped that the honored Chancellor of the University, Lord Strathcona, will be present to read the address of welcome. It is expected that the Duke will unveil the tablet which is to be placed in the medical students' room in memory of Major Harold Borden, of the Canadian Mounted Rifles and Gunner O'Reilly, of the Royal Canadian Artillery, both of whom were medical students at McGill, and both of whom lost their lives in South Africa during the course of the present war.

One Cause of Disease which has been traced to the use of canned or tinned goods has recently been the subject of investigation on the part of the Department of Inland Revenue at Ottawa. About a year ago letters were sent out from the Department addressed to some 4,348 medical men in the Dominion of Canada, asking whether any cases of illness from the use of tinned goods, had come under their notice within recent years. Out of this number some 1,313 replied, of whom 1,059 replied in the negative and the balance, some 254 replied affirmatively. On this account the Department deems it expedient in the public interest to issue instructions and precautions to safeguard the public health. If one is to judge from the replies received from physicians, the number of cases of disease apparently attributable to the use of tinned goods would average 138 per annum in Canada in an average period of about seven years. There was a total of fifteen cases reported which terminated fatally.

How to Save the Lives of Small Infants, or how to decrease the large mortality rate amongst infants in Montreal is a problem which local physicians have been trying to solve for some time past. In the Grey Nunnery Institution hundreds of infants are received yearly; and according to the books 96 per cent. of them die within a few weeks of their admission. Dr. Rottot, who has been house doctor for the past thirty years, states that for a number of years the percentage was even greater than this. Incubators have been frequently tried, but without any success. Abandoned children are on the increase; and for the last couple of years the number of children brought to the city institutions has increased to an astonishing degree, and as a result the question of trying to save the little lives has become more and more important. A decided effort is being now put forward and a new incubator sys-

tem, that which has been on exhibition at the Pan-American, has been introduced into the Grey Nunnery Maternity Hospital, and gradually into other homes in the city; and it is thought that along with an improved milk supply that much good will in the future be accomplished where in former times, all, or nearly all was a failure.

The Report of the Criminal Statistics for the year ending 30th of June, 1900, is being issued by the Dominion statistician. The number of charges in 1900 for indictable offences in Canada was 249 more than in 1899, there being 8,419 in 1900 and 8,170 in 1899. The convictions number 55 more than in 1899. In the Yukon there were 95 cases of convictions in 1900. The total convictions of males were 5,430, and of females 328, against 5,384 males and 329 females in 1899. By provinces the numbers for 1900 were: Territories and Yukon, 3,296; British Columbia, 2,994; Ontario, 18,419; New Brunswick, 2,311; Manitoba, 1,692; Quebec, 9,917; Nova Scotia, 2,595; P. E. I., 429.

The Executive Committee of the National Sanitarium Association met August 7th, at the Muskoka Cottage Sanitarium, Gravenhurst. The committee expressed great satisfaction with the condition of the buildings and the beauty of the grounds and the situation. The physicians reported an ever increasing number of applicants in whom the disease was too far advanced for successful treatment. The Gravenhurst Free Hospital for Consumptives is being got well under way. This new institution is to be supported by voluntary contributions, and is intended for consumptives in the early stage of the disease. The plans of the Toronto Home for Consumptives were also inspected and discussed. When completed, it is intended that this institution, situated near the city of Toronto, will be utilized for clinical instruction in tuberculosis.

The Governors of the Western Hospital, Montreal, are discussing plans for the erection of a new modern building at a cost of \$100,000. For quite a few years past the Western Hospital has been running on a good financial basis, and it is thought that the time is now opportune for the erection of a new building.

MISCELLANY.

Obituary.—Dr. Stephen Foss, at Brooklyn, N. Y., August 2, aged 75 years—Dr. Henry Armgardt, in Germany, on August 1, aged 52 years—Dr. Henry Buckingham Horbeek, at Charleston, S. C., August 3—Dr. J. Walter Downer, at Baltimore, Md., August 10, aged 46 years—Dr. Arthur B. Marshall, at Wytheville, N. Y., August 5—Dr. B. H. Kettrel, at Fourth Lake, N. Y., August 18—Dr. Alfred A. Dana, at Bronxville, N. Y., August 21.

Bacteria and Animal Food.—To the researches of bacteriology an interesting contribution is made by some experiments which have just been completed by Dr. Ford, of Montreal, states the *Sanitary Record and Journal*. Dr. Ford has examined the domestic animals with a view to classifying their characteristic bacteria. He found that, for instance, the bacteria in dogs and cats were similar, but differed from those in rabbits and guinea-pigs. This is in part what would have been expected, seeing that the carnivora eat different food from herbivorous animals. Bacteria being largely vegetable, each animal would become the receptacle for an intestinal fauna which was recruited from the food the animal ate. But the research has another point of interest, because it may help to make clear the reasons which lead to a change of form in the same bacillus when it has its environment in different hosts.

Discoloration of Milk.—Cows' milk is colored blue by the bacillus pyocyaneus; blue, slimy, and bitter by tyrotoxicum; yellow by the bacillus synxanthus; violet by the micrococcus prodigiosus; and reddish-yellow in rinderpest, owing to the presence of blood.

Egyptian Medical Congress.—An Egyptian Medical Congress, states the *British Medical Journal* is to be held under the patronage of the Khedive at Cairo from December 10th to 14th, 1902, under the presidency of Dr. Abbate Pacha. The Honorary Presidents are Dr. Ibrahim Pacha Hassan, Dr. Pinching, and Dr. Ruffer. The General Secretary is Dr. Voronoff. The work of the Congress will be divided among three sections, as follows: (1) Medical Sciences, presided over by Dr. Comanos Pacha; (2) Surgical Sciences, presided over by Dr. H. Milton, and (3) Ophthalmology, presided over by Dr. Mohammed Bey Eloui. The programme of the Congress will include discussions on affections especially rife in Egypt, such as bilharzia, ankylo-

stomatitis, bilious fever, abscess of the liver, etc. Special attention will be given to questions relative to the epidemics which for some years past have regularly visited Egypt, and the prophylactic measures to be taken against them. The following papers among others have been promised: Alcoholism and Its Increase in Egypt, by Dr. De Becker; The Frequency of Hydrocele in Egypt and Its Treatment, by Dr. Colloridi; Myxedema in Egypt, by Dr. Brossard; Plague, by Dr. Gotschlich; and Tuberculosis in Egypt, by Drs. Ibrahim Pacha Hassan, Eld, and Sandwith.

Smallpox in the United States.—Washington.—The public health report issued by the Marine Hospital Service shows the existence of 8,258 cases of small-pox in the United States, against 3,432 at the same time last year.

A Peculiar Consultation.—It is a rather novel idea for an author to call in his family physician in consultation regarding the symptoms of one of his characters. But this, it seems, is just what Mr. Harold McGrath did while writing "The Puppet Crown." He had just finished the chapter describing the "fight on horseback," and feeling that the situation had got rather beyond his own powers, detailed the facts to the doctor, and asked what could be done to save the hero. "Save him, my boy?" replied the old gentleman, gravely; "he is beyond the power of human aid. Science can do nothing for him. Art can only put him out of his misery." Mr. McGrath adds that after the publication of the book he received a bill from his physician for professional services.

Changes in the Medical Corps of the Navy. For week ending August 24th, 1901.

ASSISTANT SURGEON C. R. BURR, detached from the "Monongahela," ordered home, granted leave of one month, and resignation accepted to take effect at the expiration of that period.—Aug. 20.

MEDICAL DIRECTOR T. J. TURNER, retired, died at Mackinac Island, Mich., August 20, 1901.—Aug. 23.

P. A. SURGEON D. H. MORGAN, detached from Norfolk Hospital, and ordered to the Monongahela, August 26.—Aug. 23.

P. A. SURGEON D. A. CARPENTER, detached from the "Franklin" and ordered to the Norfolk Hospital.—Aug. 23.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended August 22, 1901.

H. R. CARTER, surgeon, granted leave of absence for 14 days from August 20, 1901—August 16, 1901.

Leave of absence granted Surgeon Carter by Bureau letter of August 16th revoked—August 21, 1901.

J. C. COBB, passed assistant surgeon, granted ten days' extension of leave of absence—August 21, 1901.

J. B. STONER, passed assistant surgeon, granted leave of absence for 17 days from September 2—August 22, 1901.

G. B. YOUNG, passed assistant surgeon, granted 8 days' extension of leave of absence from August 22—August 16, 1901.

L. D. FRICKS, assistant surgeon, relieved from duty in the Philippine Islands, and directed to proceed to San Francisco, Cal., and await orders—August 20, 1901.

M. K. GWYN, assistant surgeon, relieved from duty at Louisville, Ky., and directed to proceed to San Francisco Quarantine and report to the medical officer in command for temporary duty; thence to proceed to Manila, P. I., and report to the chief quarantine officer for duty—August 20, 1901.

T. D. BERRY, assistant surgeon, relieved from duty at Cienfuegos, Cuba, and directed to proceed to Louisville, Kentucky and report to the medical officer in command for duty and assignment to quarters—August 22, 1901.

EDWARD FRANCIS, assistant surgeon, relieved from duty at the Immigration Depot, New York, N. Y., and directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty—August 22, 1901.

R. C. CRAIG, acting assistant surgeon, granted leave of absence for 30 days from August 31—August 21, 1901.

W. R. HICKS, acting assistant surgeon, granted leave of absence for 16 days from August 15—August 16, 1901.

M. WALTERS, hospital steward, granted leave of absence for 7 days from August 1 under paragraph 181 of the regulations.

R. F. TROXLER, hospital steward, granted leave of absence for 1 month from August 20—August 16, 1901.

J. E. BECK, hospital steward, granted leave of absence for 3 days from August 15, under paragraph 181 of the regulations.

M. H. WATERS, hospital steward, granted leave of absence for 17 days from September 3—August 20, 1901.

BOARD CONVENED

Board convened to meet in Philadelphia, Pa., August 21, 1901 for the physical examination of an applicant for appointment as Lieutenant in the Revenue Cutter Service.

Detail for the Board Surgeon H. W. Austin, chairman; Assistant Surgeon J. S. Burgess, recorder.

GREAT BRITAIN.

Appointment.—Sir Francis R. Cruise, M. D., Fellow and ex-President of the Royal College of Physicians of Ireland, has been appointed one of the honorary physicians to His Majesty the King in Ireland.

To Regulate the Sale of Cocaine.—The English authorities are seriously considering the expediency of adding cocaine to the list of poisons governed by the Poison Act of England of 1868, on account of the suicide of two young women in London which recently occurred from cocaine.

CONTINENTAL EUROPE.

Professor Luigi Mangiagalli, Director of the Obstetric and Gynecological Clinic at the University of Pavia, has been nominated a member of the Supreme Council of Public Instruction for the Faculty of Medicine.

Dr. Francis Neugebauer, Director of the Gynecological Clinic of the Evangelical Hospital at Warsaw, was recently appointed a Foreign Corresponding Member of the Academy of Medicine of Paris.

The French National Periodical Congress of Gynecology, Obstetrics and Pediatrics will assemble for their third meeting at Nantes on September 23-30, under the general presidency of Dr. Sevestra, of Paris, who will also preside over the Section of Pediatrics. Dr. Segond, of Paris, will be President of the Section of Gynecology, and Professor Queirel, of Marseilles, of that of Obstetrics. The questions to be considered in the Section of Gynecology are: (1) Congenital anteversion of the uterus as a cause of sterility, and its treatment; (2) causes favoring ectopic gestation; (3) dystocia due to fibroids. In the Section of Obstetrics the programme is: (1) Rupture of the uterus; (2) inversion of the uterus; (3) the fate of prematurely-born children; (4) the uncontrollable vomiting of pregnancy; (5) radiographic measurement of the pelvis. In the Section of Pediatrics the following questions will be discussed: (1) Arthritis in children; (2) meningitic manifestations in the course of digestive infections in childhood; (3) intermittent albuminuria in the child; (4) the defense of childhood (pueri-culture, suckling, weaning); (5) conservative methods in the treatment of local tuberculosis; (6) scoliosis, its treatment by kinesitherapy (movement cure).

Appointments at Heidelberg.—Dr. Julius Hegener has been recognized as privat-docent of Otology and Dr. Martin Jacoby as privat-docent of Pharmacology. Dr. H. Braus, of Würzburg has been appointed Extraordinary Professor of Anatomy.

A German View of American Students.—The *Deutsche medicinische Wochenschrift* states that, according to the *Vorddeutsche allgemeine Zeitung*, the Medical Senate at Heidelberg, in response to a petition from the clinicians of that city, will only permit such foreign students to enter the medical course as have successfully passed an examination equivalent to the German examination requisite for matriculation at a University. In addition the *Journal of the American Medical Association* states the following relative to this subject: The *Rhein. Westphal. Zeitung* states that American students who study at German universities are generally less educated than the students in the *tertia* of their gymnasia (high schools). It says: "Here they study superficially and then pose as German physicians in the United States. The result is that German physicians no longer enjoy the reputation in the United States they once did. There is all the difference in the world between a German physician and a physician superficially educated in Germany, because he lacks preliminary education." German newspapers urge that unless the students from the United States acquire sufficient knowledge to fit them for a university course they should be excluded from the German universities.

Statistics of the German Universities.—The *Deutsche Medicinal Zeitung* gives the number of medical students attending the Universities of Germany, Austria and Switzerland, during the winter of 1900-1901. Berlin leads the list with 1313, Munich had 1274, Vienna 1188, Leipzig 626, Würzburg 543, Berne 434, Freiburg 357, Geneva 357, Graz 352, Kiel 350, and Erlangen 333. All the others had under 300 students.

Tuberculosis and the German Workmen's Insurance.—Privy-Councillor Blefeldt, President of the Senate in the Imperial Insurance Department, stated at the British Congress on Tuberculosis that since the year 1891 all hired workmen in Germany, the number of whom was estimated at 12,660,000 in 1898, have been insured against sickness; that is to say, employer and workman contribute in equal parts, so as to provide an annuity to be given to all persons who are incapable of self-support or over seventy years old. The insurance is effected under the supervision of the Imperial Insurance Department, State Insurance Departments, thirty-one insurance institutions territorially limited, and nine special club institutions of the Invalidity Insurance. These insurance offices and club institutions, the capital of which, at the end of 1899, after the ninth year of their existence, amounted to almost 761,000,000 marks, and which will increase from year to year, take a financial interest in postponing as long as possible the invalidity of the insured with which they are charged, because the later the insured are entitled to the use of the lawful annuity the longer their contributions for invalidity insurance are paid, and consequently the time from the beginning to the end of the payment of the annuity becomes the shorter. For this reason it was of greatest importance for the officers of the Invalidity Insurance to ascertain the cause of the Invalidity Insurance made by the Imperial Insurance Department, so as to battle against such causes effectively. The statistics of the causes of Invalidity, made by the Imperial Insurance Department, embracing in all 158,462 pensioners, shows by published graphic tables the following: Of all male workers employed in mining, metallurgy, industry and building, who become invalided up to the age of thirty, more than half suffer from consumption. The proportion of the female pensioners in the same avocations is just as unfavorable at the age of 20-24, while at the age of 25-29 almost half of all invalid women of these avocations are consumptive. Persons engaged in forestry and agriculture do not become invalided in consequence of this illness to so great an extent; nevertheless out of 1,000 male pensioners employed in agricultural work, there are more than 350 consumptives of the age of 20-24. For the total of the other professions, the proportion of invalid men of the age of 20-30 is such that of 1000 cases of invalidity 450 are cases of pulmonary consumption, while about a fourth part of all invalid women of the same age and professions are consumptive. These results and the statistics of the causes of death, which are published by the Board of Health for the year 1893, prove that of every 100 persons who died at the age of 15-60 in the German Empire thirty-three were victims to consumption. The officers of the German Workmen's Insurance found that to battle successfully against consumption was one of the most important tasks.

The Evasion of the Child-labor Law in Russia.—In a certain match factory two little girls each about 7 years old and several boys and girls between the ages of 10 and 12 are made to hide themselves under the skirts of the older working girls or behind boxes, whenever the inspector comes around. We fear that this evasion of the inspector is not at all uncommon even in our own large cities in which the "sweat-shops" exist.

A New "Gastronomic" Machine.—The *Bolnitchnaia Gazeta* Botkina tells of a peculiar machine unearthed by the police in one of the Moscow restaurants. The machine is supplied with a large pipe into which all the remnants from the tables are thrown and by turning a crank converted into cutlets, pastry and other tempting dishes. There is evidently some ground for the popular notion that dogs are converted into sausages by the aid of special machines.

Leprosy in Russia.—A number of cases of leprosy are reported from several points in the government of Koursk. Several of the affected persons never left their homes and therefore could not have acquired the disease at any other place. It is noteworthy that all of the cases occurred in perfectly healthy families and amidst favorable surroundings.

An Antituberculosis Society.—A new society is being organized in Moscow for the purpose of carrying into practice the means suggested by science for the prevention of tuberculosis. The members of this society will be physicians as well as laymen.

Compulsory Tuberculin Test.—The Council of Koff proposes to ask for a law compelling the dairymen to make use of the tuberculin test.

Oxygen to be Kept at Fire Stations.—The city of Berlin requires that a supply of oxygen gas shall be kept at every fire station and shall be carried by every fire wagon to be used in cases of poisoning by morphin and carbon monoxid.

Resorcin in Hair Dye.—A case of poisoning from hair dye in Paris was found to be due to the resorcin it contained. There were symptoms of chronic dyspepsia, and during three years the patient had sixteen attacks of erythelas.

Female Students in European Universities.—According to the *Deutsche Med. Wochens.*, there are, excluding Munich, 95 female medical students in Germany, of whom 56 are foreign. They are distributed as follows: Berlin 25 (21 foreigners), Leipzig 24 (22 foreigners), Freiburg 18 (14 foreigners), Halle 12 (9 foreigners), Heidelberg 6, Bonn 5, Strassburg 2, Breslau 2, and Königsberg 1. In Switzerland, Berne University has 188 females (180 Russians), Zürich 85, and Lausanne 61.

On the Psychical Nature of Some Disturbances of the Acts of Urination and Defecation.—K. Oppenheim (*Medicinskoje Obozrenie*, June, 1901) claims that the nervous origin of some forms of the disorders of the bladder and bowels does not receive the attention it merits. He reports from his private practice the following cases: Case 1. Mrs. X. suffered from frequent desires to urinate whenever she was in society, especially at concerts and theaters. At such times she experienced a painful sensation to empty her bladder, accompanied by a feeling of fear, a flow of blood to the head and face and cold extremities. Urination was followed by relief which sometimes lasted but a few minutes, when the painful desire appeared again. The larger the room and the more people in it, the worse was the affection. At home or at the proximity of public urinals she was entirely free from the irritability of the bladder. The patient was relieved by hydrotherapy and placebos, which had the effect of suggestion. Case 2. The patient, an engineer, suffered from insuppressible desire to move his bowels whenever he happened to be in society. Like in the above case, his desire was associated with a feeling of fear, flushes of heat, and congestion of the face. As soon as he left the room the painful sensations disappeared; often he would have a free liquid evacuation of the bowels. His mother was subjected to the same affection. Case 3. A woman, 38 years old, of a nervous family and herself very nervous complained of pain and paresthesia in the left side, excitability and other nervous phenomena. She suspected heart disease and wanted to be set at ease on that point. She also suffered from irritability of the bladder similar to Case 1. She was cured by Weir-Mitchell's rest cure, hydrotherapy and electricity. Case 4. A student, 20 years old, of a neurotic family presented conditions similar to Case 2. The author also reports the case of a girl of 9 who fell from a ladder without, however, sustaining any injury. She developed a train of symptoms characteristic of tic convulsif, associated with extreme irritability of the bladder and bowels. [A. R.]

On the Treatment of Extra-Uterine Pregnancy.—Fedoroff (*Medicinskoje Obozrenie*, June, 1901) reports the results of 27 operations for extrauterine pregnancy performed at the Moscow Basman Hospital. In 3 cases colpotomy was performed, in 2 of total extirpation through the vagina and in 22 laparotomy. In 2 the pregnancy was interstitial, in the others tubal. The ages of the patients varied from 25 to 30. In 4 there was no interruption of the normal menstruation, in 9 menstruation did not occur for 5-6 weeks, in 4, 7-8 weeks, in 7, 2-3 months. In one case there was a pregnancy of 4 months with a dead fetus (lithopedion). Only in 8 was there no previous history of diseases of the uterus or adnexa. Of 19 cases carefully studied, 10 showed changes in the tubes, ovaries and pelvic peritoneum. As to the results, 22 laparotomies gave 1 death, in the case of the lithopedion; of the 2 total extirpations one ended fatally, owing to internal hemorrhage which occurred 5 hours after the operation. In all others the results were favorable. In many cases life was saved by timely operation. The author prefers laparotomy to any of the other operative routes. (A. R.)

1. Introductory Remarks Made at the Opening of the Section of State Medicine.

SHIRLEY F. MURPHY.

2. A Discussion on the Relation Between County and District Sanitary Administrations. F. T. BOND, G. H. FOSHROKE, J. L. ROBERTS, E. C. SEATON, H. MAY, T. W. H. GARSTANG, E. J. SLADEKING, J. GROVES, H. JONES, W. SMITH, W. C. C. PAKES, A. K. CHALMERS, J. M. MARTIN, D. S. DAVIES, and SHIRLEY F. MURPHY.
3. Plague and its Prevention as a Disease Communicable from Animal to Man. D. S. DAVIES.

3.—The records of the Sydney outbreak of plague, in 1900, confirm in every particular the conviction that has surely been accumulating from the more or less complete records of other outbreaks, that plague in man is a secondary event dependent upon plague in animals, and that, therefore, success in the suppression of human plague depends upon the adoption of adequate measures for the suppression of rat plague. Davies believes that the policy to follow in order to accomplish this result is to secure rat-free merchant ships. This is a possibility if the vessels that engage in the coasting trade and that make voyages of 3 weeks or a month are fumigated at the point of departure before loading, and at the ultimate port touched on the voyage. When this routine is followed, often no rats will be found on the vessels after the second fumigation. The method is successfully carried out under inter-colonial agreement, which requires vessels to produce a certificate of fumigation, without which they are subject to detention. [J. M. S.]

6. The Electrolytic Transmission of Sulphur from the Harrogate Sulphur Water Through a Pig's Skin, and Its Therapeutic Value on the Human Subject under Similar Circumstances in Eczema, Gout, etc. FRANCIS WM. SMITH.

1. Steven delivered a lecture in the Glasgow Royal Infirmary on "Mitral Disease." He gives a short summary of the ten cases which were under his observation when this lecture was delivered. Case 1.—This occurred in a married woman of 21 years of age who, on admission to the hospital, was suffering from acute rheumatic fever. The pulse rate varied between 80 and 90 per minute. It was regular in force and rhythm and of good tension. At the apex there was heard a soft ventricular-systolic murmur. There were no signs of cardiac hypertrophy. Case 2.—This occurred in a married woman 37 years of age. This patient complained of dull precordial pain, palpitation and occasional faintness. The illness had existed for nine weeks, and originated during her last confinement. Fifteen years ago she had suffered from rheumatic fever. On examination the apex beat was four and a half inches to the left of the midsternal line in the fifth interspace. The impulse was diffused. Auscultation revealed a loud ventricular-systolic murmur at the apex. At the base the second sound was reduplicated. In the tricuspid area and in the third left interspace, two murmurs were present, namely, a ventricular diastolic and a ventricular-systolic murmur.

The pulse rate averaged from 65 to 70 per minute. The pulse was easily compressed. Case 3.—This occurred in a married woman 27 years of age. She had complained for five months previous to admission, of increasing dyspnea and edema of the lower limbs. She had an attack of rheumatic fever 15 years ago. The apex beat was found in the fifth interspace five inches to the left of the midsternal line. At the apex, a musical ventricular-systolic murmur was heard. In the fourth left interspace, a ventricular-systolic and a ventricular-diastolic murmur existed. The pulmonary second sound was accentuated. Case 4.—This occurred in a girl 12 years of age, who had been suffering from mitral regurgitation and stenosis for 14 months. Between the ages of 5 and 7, she suffered from chorea. On admission, she was in the midst of an attack of rheumatic fever. The apex beat was found four inches to the left of the midsternal line in the sixth interspace; at this point there was heard a loud ventricular-systolic and a ventricular-diastolic murmur. The ventricular-diastolic murmur was limited to the apex region. The pulmonary second sound was accentuated. Case 5.—This occurred in a girl 11 years of age who, on admission, was suffering from chorea. At the apex there was heard a soft systolic murmur. The pulse was small, irregular, and easily compressed. Case 6.—This occurred in a female child nine years of age who had complained of shortness of breath, general weakness and slight pains in the joints. The pulse was found small and easily compressed, and a loud ventricular-systolic murmur was heard over the apex. At the base and at the apex the second sound was greatly accentuated. Case 7.—This occurred in a man 37 years of age who had been suffering from mitral regurgitation with hypertrophy and dilatation of the left ventricle. A history of rheumatic fever could not be ascertained. The apex beat was four and a half inches to the left of the midsternal line in the fifth interspace. An occasional diastolic thrill was felt over the apex, and at this point a loud systolic murmur was heard which was transmitted to the axilla. Case 8.—This occurred in a married woman 53 years of age who, on admission, was suffering from cardiac dilatation. A rheumatic history could not be obtained. The pulse was regular both in force and rhythm, and its rate was 110 per minute. The apex impulse was situated four inches to the left of the midsternal line in the fifth intercostal space. A soft ventricular-systolic murmur was heard at this point. Case 9.—This occurred in an unmarried woman 21 years of age who had been suffering from mitral regurgitation with dilatation of the left ventricle. In childhood, she suffered from scarlet fever and measles. A rheumatic history, however, could not be obtained, but the patient admitted having complained frequently of severe growing pains. There was edema of the lower extremities and the pulse was irregular in force and rhythm. The apex beat was situated four and a half inches to the left of the midsternal line in the fifth interspace, where a loud ventricular-systolic murmur was heard, accompanied by a distinct systolic thrill. Case 10.—This occurred in a child twelve years of age. This patient had previously suffered from attacks of hemoptysis. The apex beat was found two and three-quarter inches to the left of the midsternal line in the fifth interspace, where a distinct presystolic thrill was felt and a loud auriculo-systolic murmur was heard in the region of the apex. In a summary of these cases, the author points out that in general terms they represent fair clinical characteristics of mitral disease. He states that there are two murmurs which indicate fairly actual disease of the mitral curtains, namely, a direct murmur denoting stenosis of the valve, and another direct murmur occupying the long pause, which is diastolic in rhythm and limited to the region of the apex. Both are essentially produced by the same mechanism. He also calls our attention to the fact that the ventricular-systolic murmur heard at the apex and conveyed toward the axilla does not always indicate structural disease of the mitral curtains. We must depend upon other phenomena to assist us in making the diagnosis of disease of the mitral valve. He states that rheumatism, chorea, and embolism are valuable clinical aids in arriving at a diagnosis. In regard to the age in which mitral disease is most common, he reminds us that it is most frequent during the early periods of life, and that when it occurs in the later decades, its associations with the organic affections of the myocardium, should be borne in mind as the most frequent primary cause. The physiognomy of mitral disease is quite characteristic and stands in bold contrast to that of aortic

regurgitation. In the former condition there is a more or less livid hue of the features, while in the latter condition, marked pallor is striking. In this series 60% of the cases were associated with rheumatism. The typical and characteristic pulse of the mitral disease shows marked irregularity in force and rhythm, and this irregularity occurs comparatively early in the course of the disease—long before the signs of failing compensation manifest themselves. Another point worthy of note is the increased frequency of the pulse rate.

[F. J. K.]

2.—Abstract will appear when the remainder of the article is published.

3.—Hayward communicated an article to the British Congress on Tuberculosis "on the mortality from phthisis and from other tubercular diseases considered in some aspects which may be demonstrated by means of life-tables." This author has included in his article a number of life-tables. He calls our attention to the remarkable statement that if there had been no phthisis there would have been an increase of two and a half years in the life of each individual born. [F. J. K.]

4.—Jennings writes "on the physiological cure of the morphia habit." In the management of this condition, Jennings recommends the withdrawal of the drug as rapidly as possible and still as slowly as is necessary to effect a cure without causing distress to the patient. He lays particular emphasis on the fact that when giving up morphia, it is principally a question of depriving the individual of a stimulant. The vital collapse which follows its withdrawal is largely due to the lack of its stimulating action. For this reason the author administers digitalis or spartein. He lays great stress on the necessity of administering bicarbonate of soda for the hyperacidity of the stomach, which is a great factor in producing the craving. Another measure which he has found extremely valuable is the hot-air bath. The article is concluded with the report of ten cases. [F. J. K.]

5.—Sladen contributes an article on "pasteurization of infected milk." This author claims that the danger of using milk that contains pathogenic micro-organisms appears to be removed by heating the milk to 85° C. He states that clinical evidence of the transmission of tuberculosis by milk is fairly strong. Reference is made to the following instance. Three cows, of a dairy in Scotland, suffering from tubercular disease of the udder, were the source of an outbreak of tuberculosis in an institution, where the milk from these animals was used. The author also refers to a number of other instances which point to the likelihood of tuberculosis being transmitted by milk. Our attention is also directed to the interesting statement that the frequency of tubercular diseases following measles, scarlet fever, smallpox, and similar conditions, may be largely attributed to infected milk. [F. J. K.]

6.—Smith discusses the electrolytic transmission of sulphur from the Harrogate water through pig's skin. By means of an electric current, he was able to demonstrate that the sulphur which was a constituent of the Harrogate Sulphur Water, penetrated pig's skin. This author has employed a constant current of electricity in conjunction with Harrogate Sulphur Water baths in the treatment of cases of eczema, gout, rheumatism and peripheral neuritis, and he found that such patients improved more by this method than by sulphur baths without electricity. He suggests that it seems reasonable to assume that sulphur is driven through the living skin by electricity. [F. J. K.]

MEDICAL RECORD.

August 24, 1901.

1. The Prognosis of Traumatic Hysteria.
PEARCE BAILEY.
2. Infantile Typhoid Fever.
AUGUST ADRIAN STRASSER.
3. A Series of Mastoid Operations.
CHARLES H. MAY.
4. The Zoological Distribution of Tuberculosis.
WOODS HUTCHINSON.
5. Bifocal Lenses, etc. JOHN E. WEEKS.

1.—Pearce A. Bailey discusses the prognosis of traumatic hysteria, based upon the subsequent histories of a number of litigated cases. In hysteria the normally transmitting

and normally registered sensory stimuli in some subtle way fail to be transferred to the association system, hence they do not enter into the practical life of the individual, and do not attain an intellectual value. The patient consequently is in the anomalous condition of feeling, seeing, hearing, tasting or smelling, as the case may be, without being aware that he does so; or from similar or complex causes, he may lose the power of originating voluntary motor impulses, and be for all practical purposes, paralyzed. Yet the belief of the patient as to his own incapacity is absolute, and often so persistent as to deprive him of his usefulness for considerable periods of time. Since the belief is false, and since false beliefs which dominate and disorganize the life of an individual are insane delusions, hysteria, says Bailey, is to be classed with delusional insanities. Some nine cases are detailed, giving the effect upon the patient of the litigation of their cases, and from these cases it will be seen that there is the same uncertainty regarding prognosis in traumatic hysteria which characterizes all mental affections. The influence of heredity is one of the most important considerations in the prognosis. The older the patient the greater is the danger that the symptoms will be permanent. The previous condition of health is also a factor. It may be said that the chances for recovery from traumatic hysteria in a healthy person not over 35 or 40 years of age, are generally very good, but not absolutely certain. With increasing age, the prognosis becomes rapidly worse. In conclusion Bailey discusses the difficulties which the physician encounters as a medical witness in cases of this character.

[T. L. C.]

2.—A. A. Strasser reports two cases of infantile typhoid fever. One of these cases was traceable to infection from ground water, and the other from a common drinking cup in a Newark department store. Some general guides are given as to the treatment. [T. L. C.]

3.—May reports 8 cases presenting symptoms of mastoiditis. The most interesting of these are a case of chronic purulent inflammation of the middle ear with chronic mastoiditis followed by an abscess of the temporo-sphenoidal lobe, necessitating trephining, and a case of acute bilateral suppurative mastoiditis occurring in the course of diphtheria. There was no diphtheritic infection of the mastoid wound. [F. T. S.]

4.—Woods Hutchinson presents a paper on the zoological distribution of tuberculosis, his object being to make a contribution to the study of the problem of the factors which determine susceptibility to tuberculous infection. He presents a preliminary report of his observations in the post-mortem room of the Zoological Gardens in London during the winter and spring of 1898-1899. He briefly discusses the relative value of the three great predisposing factors—race, food, and housing in animals, in the light of the death records of the Gardens for the past five years. As to family or race in mammals, the highest order (primates), is by far the most liable per 100 living, while next comes the marsupials. Ungulates and carnivora, which are usually ranked as on about the same level of specialization, are widely separated, the former having six times the death-rate of the latter. Within the order of the ungulates itself, the most striking contrasts occur the odd-toed being almost completely exempt, even horses and asses under domestication, while the even-toed are extremely liable, but there are marked differences even among the families of this last sub-order. His figures appear to show a greatly increased susceptibility of the disease among vegetable feeders and a much reduced liability among meat-eaters, both mammals and birds. It appears that there is some influence connected with the food habits of both mammals and birds depending upon their liability to tuberculosis. Another factor which seems to the author a far more important element, is the resultant habits of life and the vigor and endurance entailed by them. When from any cause this higher degree of vigor has been acquired by herbivora, immunity from tuberculosis follows, and as the degree of this vigor is best indicated by the heart and bodily weight, he has arranged his orders and groups according to this character. In our own species it has been suggested that the size and vigor of the heart is an important part in the predisposition to tuberculosis. Altogether the conclusion to which this question of the distribution of tubercle points is that it is a matter of vigor, endurance and resisting power, rather than of race, food, or exposure to infection, and as those powers

are usually higher in flesh-eaters than in vegetable feeders, the former possess a marked relative immunity.

[T. L. C.]

MEDICAL NEWS.

August 24, 1901.

1. Further Notes Upon the Diagnostic Test of Tuberculin. EDWARD O. OTIS.
2. A Study of Burns, with a Plea for Their More Rational Treatment. FREDERICK GRIFFITH.
3. Carbolic Acid in Burns. OTTO L. MUENCH.
4. Inertness of Petroleum Compounds When Given Medicinally. ROBERT REYBURN.
5. Strangulated Hernia of the Bladder; Ruptured Sarcoma of the Testis Mistaken for Strangulated Hernia. THOMAS H. MANLEY.

1.—E. O. Otis collected thirty-five cases in which the tuberculin test was used in syphilis. The smallest amount of tuberculin used was two mgs., the largest ten mgs. There were six undoubted reactions and five what he called abortive reactions. Considering only the six undoubted reactions he had 17% of reactions; including the abortive cases, he had 31%. In the author's second series of twenty-six cases of suspected or proved tuberculosis eight cases in which the physical examinations showed sufficient evidence of tuberculosis or in which tubercle bacilli were found in the sputum, he had four reactions and four failures to react. In three cases in which tubercle bacilli were found in the sputum, two did not react; in one 7 mgs. were used, and in the other 5 and 10 mgs. In the three cases in which 2.5 and 8 mgs. of tuberculin were successfully used, only a local reaction was obtained. The remaining eighteen cases of suspected tuberculosis, there were six reactions and twelve failures to react. In no one of those cases which failed to react could tuberculosis be more than suspected, with greater or less probability, by the physical examinations. A case of lupus of the face, besides giving a general reaction, showed a very pretty local one. A case of chronic laryngitis in which either syphilis or tuberculosis might have been the cause, a reaction was obtained, thus leaving the origin doubtful as before. Otis advises, after going over the subject very carefully, that in using the tuberculin test for suspected tuberculosis, experience teaches that we should look carefully for syphilis. [T.M.T.]

2.—F. Griffith in his article sums up the treatment as follows: (1) Burns are the commonest of injuries and of all wounds they are treated least in accordance with now universally taught and accepted surgical principles. (2) Burns may be divided into two degrees of severity; burns of the first degree involve the skin only, those of the second degree include all others. (3) The pathology of burns, is the pathology of inflammation of the part locally affected with almost all the morbid changes possible in the complications which result. (4) Early death and internal complications after burns are due to direct action of heat, with fragmentation and vital change in the blood-corpuscles; later effects are due to infection taking place from the burned area. (5) The condition of the granulations during the healing of burns is the determining factor in the amount of contraction and subsequent deformity which takes place. The greater the friction caused by irritation from whatever source, the larger will be the granulations, the greater the amount of connective tissue and the greater will be the contraction. The local treatment of burns from the earliest times has been along the lines of prevention of irritation, but the late advances made in wound treatment have not been followed out in these. (6) The burn wound should be cleansed of as much dead, burned tissue as possible; the thoroughness with which this clearing away of the eschar is done will determine in a great measure the amount of future discharge, and the presence or absence of infecting organisms. (7) Hydrogen dioxide to wash away the debris and render aseptic the denuded parts is the best antiseptic at our command; rubber tissue in strips should be laid on the wound to prevent contact with the absorbent dressing. (8) The use of splints to secure relaxation and retention in obtaining rest for a burned part is of great importance and is as much indicated in this form of injury as in fractures of the contiguous bones. (9) The internal treatment of burns is stimulative until reaction from shock has taken place when it becomes supportive. (10) Opium fulfills the indications for pain. In-

ternal inflammations and diarrhea. (12) The bowels and kidneys must be continuously kept open, but enemata only should be employed. (13) Watchful attention must be paid to early signs of internal complications of the viscera.

[T. M. T.]

3.—O. L. Muench in his article on Carbolic Acid in Burns says that the general result in burns treated with carbolic acid is complete exclusion of air and coagulation of the serous effusions, and that the healing process takes place with much less suffering and in a shorter time than by any other method which the author has tried. It is possible that carbolic acid poisoning may be produced by absorption in severe surgical cases when employed in too dilute a form, but the author has not seen a single case during his whole practice. Many persons think the only virtue of carbolic acid is an antiseptic one, but he thinks the exclusion of air is just as important as to prevent the entrance of microbes. [T. M. T.]

4.—R. Reyburn states that on account of the disagreeable flavor of cod liver oil many substitutes have been suggested, especially the derivatives of petroleum. These have been used quite extensively and the question arises, are the compounds of petroleum, when taken internally, absorbed and made part of the tissue of the body in the same manner as, which we know from the long experience of numerous observers, is the case when our patients take cod liver oil? It has been found by experiments that pure petroleum, while unirritating to the digestive tract, is valueless as a foodstuff. The author's experience is that when given internally it passed through the intestinal canal and the only beneficial effects it exerts in the stomach and intestines are due to its lubricating and demulcent properties. Finally, therefore, if we consider (1) the entire insolubility of petroleum and its compounds in either the gastric juice or the fluid of the intestinal canal, and (2) the fact that when petroleum is given internally the whole of it can be recovered from the feces, we are warranted in stating that petroleum can in no sense be considered a substitute for cod liver oil as a nutrient and restorative, and (3) that the usefulness of petroleum as a remedy must depend upon its unirritating and demulcent properties.

[T. M. T.]

5.—T. H. Manley gives the fundamental features in the operative technique as follows: (1) A large incision involving a laparotomy; (2) Free division of the constriction from within; (3) The deliberate, methodical and complete treatment of any important complication then and there. It is advised, except in exceptional cases, to operate at the patient's home on account of the ill effects of moving and the possibility of infection. The mortality set down by Gibbons is 15% due to defective operative technique. The author places the mortality at 50%. [T. M. T.]

THE NEW YORK MEDICAL JOURNAL.

August 24, 1901.

1. A Case of Actinomycosis Hominis, with Remarks Concerning the Differential Macroscopic Diagnosis between Actinomycotic and Tuberculous Peribronchitis. GUSTAV FUETTERER.
2. Remarks upon the Treatment of Hip Diseases, and Presentation of a Further Modification of the Hip Splint. JOHN DANE.
3. The Treatment of Acute Hip Disease, with the Description of a Splint. ROBERT W. LOVETT.
4. A Case of Angio-Sarcoma of the Nose. STANLEY S. CORNELL.
5. The Importance of an Early and Radical Climatic Change in the Cure of Pulmonary Tuberculosis. C. F. GARDINER.
6. Sulphuric Ether in the Removal of Ceruminous Plugs. E. L. MEIERHOF.

1.—G. Fuetterer after reviewing a case of actinomycosis hominis gives the macroscopic examination between it and tuberculous peribronchitis as follows: Actinomycotic peribronchitis appears in fresh infections on cross section of small bronchi in the form of sharply defined sulphur yellow rings, with clear, round outlines, against the unchanged parenchyma of the lung which surrounds it, and above which it is slightly prominent. The process has but little tendency to involve the lung substance, which becomes affected very little, if at all. Even microscopically it can be seen that the alveoli next to the peribronchitic

area are unchanged, while occasionally a small nodular prominence of the peribronchitic ring may press against them. The cut surface of the yellow ring is quite even, and during its further development it shows a decided tendency to grow toward the centre of the lumen of the bronchus, which at last becomes entirely occluded. It is also of the very greatest importance to note that the very youngest, as well as the oldest, peribronchitic areas have the same sulphur like color, while in tuberculous peribronchitis the color is very variable. Indeed, and so long as there is no caseation, it is not yellow at all, but gray or reddish gray. But even when there is caseation the yellow color has a more grayish tinge, and is not uniform in quality. The tuberculous peribronchitic area projects above the surrounding lung tissue; they have an uneven surface and irregular outlines. There is not the pronounced tendency to grow centrally and close up the lumina, but, on the contrary, the process is very prone to spread peripherally, and an early affection of the surrounding lung tissue is the rule. Tubercular infection generally affects the apices, but actinomycosis prefers the lower portions of the lungs.

[T. M. T.]

3.—R. W. Lovett gives his routine treatment of acute Hip Disease as follows: If a case with deformity or sensitiveness, no matter how severe, is admitted for bed treatment to the wards, the traction splint is put on and over it a plaster-of-Paris spica bandage reaching from the axilla to the calf. If the leg is adducted or flexed, the spica is made to hold the leg in the position of deformity, and no attempt at correction is made at first bandaging. At subsequent bandagings the deformity has been found to have been corrected just as it would have been found by recumbent treatment and its gradual reduction by traction. One of the later plaster spicas, when removed, is used as a mold for the leather spica. [T. M. T.]

5.—C. F. Gardiner in his article on *The Importance of an Early and Radical Climatic Change in the Cure of Pulmonary Tuberculosis* states that it is well for us to remember that there has been an evolution in the west as well as in the east, regarding the use of pure air and wholesome food in treating consumption, while, in the use of pure air we have had the advantage, as quality as well as quantity should be considered. Outdoor air is not of the same quality in all climates, and does not, therefore, exert a climatic effort to the same degree taken in the same quantity. Few will doubt the difference between the air of parts of Central America and that of New York City, or we will say within twenty miles of it, but few people, even climatologists, realize that there is as marked a difference between the air of New York and vicinity and that of Colorado and New Mexico. The air of our high dry regions, such as our altitude in Colorado, has a special quality not yet recognized in a strictly scientific way. It is not alone dry, but it is air that has a special quality, due to its having been purified by the rays of the sun over vast areas absolutely uncontaminated. It is not alone the effect of such air, when breathed by the consumptive, upon tuberculous processes in the lungs, but also its evident power of arresting the septic process, that is so marked a feature in the prognosis of every case of continual pulmonary tuberculosis that makes such climatically selected air of more value as a curative agent than that of less favored regions. In his experience, a patient will derive as much benefit from four hours spent in the dry, sunny air of Colorado as from eight hours spent in the dry and cloudy climate of some parts of the east. In a dry climate, patients can be kept out of doors day and night, summer and winter, with benefit and without risk. And it is this possibility of keeping patients out of doors day and night, summer and winter, that to his mind offers such decided advantages for the cure of tuberculosis. He has, during the past winter, had patients in tents and on piazzas, in the open air all the time; with proper precautions, with stoves or electric heaters and suitable clothing, there is no risk and much benefit.

He firmly believes that the truth regarding climate will prevail, and that the great sanatoria of the future will be built, where scientific facts show the best results can be obtained. The sanatoria now established by the government at Fort Bayard, New Mexico, and at Fort Stanton, New Mexico, will in time prove the marked advantage of sanitarium methods and the best climatic cure combined.

[T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

August 22, 1901.

1. Address in Surgery. SIR WILLIAM THOMSON.
2. Treatment of Delirium Tremens. J. FRANK PERRY.
3. On the Effect of Alcohol. H. G. BEYER.
4. The Management of Delirium Tremens, with the Report of a Case. V. A. ELLSWORTH.

2.—In fairly strong subjects, *delirium tremens* is a disease that ought not to be fatal if the cases are uncomplicated and properly managed. Perry is of the opinion that the liability to delirium is greatly increased by the sudden and complete withdrawal of alcohol from a patient who has been drinking to excess. This fact, however, cannot justify the popular notion that attacks can be warded off by alcohol alone. In the treatment of severe cases it is quite indispensable, and intelligently given, in proper quantities and at the right times it will often prevent threatened attacks; but medical agents are generally imperative. The steady drinker is a more frequent victim of delirium tremens than he who goes on sprees, unless the sprees are of very long duration and are accompanied by loss of sleep and the absence of proper nourishment. There are no signs that can rightly be considered absolutely indicative of approaching delirium tremens; the nearest approach to such a sign is dilation of the pupil, which can often be seen either intermittently or permanently 24 hours before the symptoms appear. There is no sovereign remedy. For the first 2 or 3 days the patient is usually allowed a small amount of liquor, depending on the amount he has been accustomed to take before the attack appeared. He is put on as nutritious a liquid diet as he can bear and the nourishment is administered every 2 hours. As substitutes for alcohol, as that substance is withdrawn, the author advises ammonia, camphor, hyoscyamus, valerian, capsicum, ginger, and the like. Since the heart usually shows signs of distress, cardiac stimulants are used, such as strychnine, nitroglycerine, digitalis, strophanthus, sparteine or *cactus grandiflorus*. Trembling of the muscles is treated with small doses of opium. Sleep is induced by the use of sulphonal, trional, chloralamid, hedonal and similar agents. On the first appearance of symptoms, the patient is to be quieted by the use, if necessary, of chloral and bromides. If the patient's heart is weak chloral is contraindicated. When chloral proves inert, as it rarely does, the other hypnotics are to be used. Musk is safer than hyoscyne hydrobromate, which may seriously obstruct the breathing. Apomorphine, intelligently used, is a valuable agent for hypodermic use, as a sedative, but it may easily be pushed too far. The caretaker for a patient suffering from delirium tremens should always be cool and calm, because, if the patient thinks that his attendant is afraid of him, he will be very much more difficult to control. Whenever possible, mechanical restraint should not be applied because as soon as the patient is strapped in bed his case becomes much more serious and his chances for recovery are greatly lessened. [J. M. S.]

3.—The immediate effect of a dose of alcohol seems to be divisible into 2 stages: (1) the stimulating stage and (2) the paralyzing stage. These effects are produced through the nervous system and not by the direct action of the alcohol on the organs and the tissues. Many experiments go to show that alcohol has no nutritive value, but that, on the contrary, it causes an abnormal destruction of the protoplasmic constituents of the body. It is, then, a protoplasmic irritant leading to its destruction, but not to its construction. On the other hand, the well-known and much talked of experiments of Atwater, show that alcohol is a food and Woodruff, of the United States Army, has put himself on record as favoring the allowance of small amounts of alcohol to the soldier in the tropics. Beyer, however, believes that the experience of the latter author was too short to warrant authoritative conclusions. He has reduced alcohol to the rank of a drug. [J. M. S.]

4.—In the treatment of a case of *delirium tremens*, Ellsworth places the patient in a strong room with unpadded walls, in which there is no furniture, and the ventilation is of the best. He allows absolutely untrammelled muscular movements of the patient in order to preserve nerve force. The diet consists of nourishing and easily digested food, the bowels are regulated, capsicum and *nux vomica* are administered internally. The author believes that alcohol and hypnotics should never be given in any form. The author has treated 500 cases with only 2 deaths. Some-

times, early in the case, an attack, may be aborted by the administration of paraldehyd as an hypnotic and if an hypnotic has to be used, the author considers paraldehyd to be the best. The report of a case is included in the article. [J. M. S.]

11. Uric Acid Inflammations of the Middle Ear, Membrana Tympana and Mastoid. CORNELIUS WILLIAMS.

1.—This abstract will appear when the article is concluded. [F. J. K.]

2.—Goldsponh says that the conservative treatment of the uterine appendages is applicable mostly to ovaries that have undergone cystic degeneration of the Graafian follicles and corpora lutea, which results in some cases as a sequel to earlier systemic infectious diseases—exanthemata, diphtheria, typhoid and the like. In other instances they partake of the nature of retention-cysts, the follicles having been prevented from rupturing and from discharging their contents normally, owing to inflammatory thickening of their walls and of the tunica albuginea. Very often the condition is that of edema in which the ova die; such a condition is called a hydrops of the follicle by some. It arises from an impeded venous circulation, i. e., a varicose condition in the ovarian circulation, such as most frequently results from descensus of the ovary, either alone or more frequently in conjunction with retroversion of the uterus. Goldsponh has made a careful study of the conditions of all patients on whom he has performed conservative surgical operations. He has succeeded in examining 97 out of 108 of the cases. He has performed the operations through a ventral celiotomy in all cases of solid or cystic tumors of the internal generative organs that do not require removal of the uterus, and are not small and uncomplicated by adhesions or septic appendages; likewise for cases in which inflammatory processes have caused extremely firm or extensive fixation of the uterus or appendages, or have left pus or its equivalent. A tube that contains pus, even if this be no longer virulent, should be removed, because its lining is too much disorganized to functionate, but in cases of some such smaller, closed pus-tubes the ovary corresponding to it or a part of it can be saved. [W. A. N. D.]

3.—Beattie remarks that the etiology of puerperal eclampsia is still a mooted question. It has been said that the disease is due to pressure upon the ureters, but if such were true one would expect to find hydronephrosis, but none has been found in cases where autopsy has been held. The bacteria which were supposed to be the germs causing eclampsia are found in all pregnant women. When the blood of the eclamptic patient is examined, micro-organisms are rarely found, and from observations one can find no positive proof that any one germ has been isolated which will cause eclampsia. The universal opinion at present is that eclampsia is due to a profound toxemia, and the origin of this toxemia is still unknown. Whatever the cause, prophylactic treatment is of the greatest importance. In addition to hygienic measures examination of the urine should be made often enough to keep one informed of its specific gravity and whether there is diminished elimination of the urea. [W. A. N. D.]

4.—Gillette remarks that during the past ten or twelve years the question of Cesarean section in the treatment of placenta previa has been from time to time brought to the

attention of the profession. Lawson Tait was one of its strong advocates. The profession, however, has been slow in accepting this doctrine and probably never will, for it is the experience of all, that, where the placenta is laterally attached and the cervix easily dilatable, delivery may easily be conducted with comparative safety. On the other hand, given a central implantation and a rigid os from any cause whatever and no more serious or fatal condition can confront the obstetrician. These are the cases which many believe demand the Porro or the classical Cesarean section. Gillette reports a case of Cesarean section done for this condition. He concludes that the cases operated upon are as yet so few in number that no accurate deductions can be drawn from it, but he believes that Cesarean section, if generally adopted for placenta previa, will reduce the fearful mortality which we now have to at most 10%.

[W. A. N. D.]

5.—Kelly describes some of the chemical and microscopic blood tests. This author gives a short outline of some of these tests, he does not, however, enter into a detailed description of any. [F. J. K.]

6.—Head performed a number of experiments upon dogs in order to demonstrate the effect of hemorrhage on the number of leukocytes. In these investigations, he first determined the number of leukocytes in the dog experimented upon. Then the animal was bled from the left femoral artery and from two to five minutes after the blood letting, a second count was made. Other counts were made 24 hours and on the seventh day after the hemorrhage. The author reached the following conclusions: (1) Immediately after the profuse hemorrhage there is a decrease in the number of leukocytes. (2) This hypoleukocytosis is soon followed by an increase in the number of white corpuscles; post-hemorrhagic leukocytosis. (3) The leukocytosis existed for a period of seven days or more. The author contends that the blood changes which are found in dogs after hemorrhage, also occur in human beings. [F. J. K.]

7.—Ballantyne writes on the antenatal treatment of hemophilia. He suggests that the field of usefulness of antenatal treatment of hereditary diseases is undoubtedly an extensive one. He reports the case in point in which hemophilia was suspected. In this instance, a good result followed the prolonged treatment of the mother during the period of pregnancy. The history of the case is as follows: Mrs. C., 34 years of age, had always menstruated profusely and had post-partum hemorrhages after two confinements. There was distinct history of hemophilia in the family. She had given birth to two sons, who were both bleeders. During the later months of her third pregnancy she was given ten grains of calcium chloride, three times daily, and also a pill containing arsenate of iron and strychnine. These pills were afterward replaced by the syrup of the phosphate of iron. At birth the child was found to be well nourished and presented no sign of hemophilia. [F. J. K.]

8.—Robinson discusses the prevention of pulmonary tuberculosis in predisposed children. We are informed that a hereditary history of tuberculosis can be obtained in about 38% of consumptives. This author discusses the method of preventive treatment which should be recommended during three periods of life, namely, infancy, childhood and puberty. During infancy great care should be exercised in the selection of the milk for the child. A healthy wet-nurse should be always selected when the mother is tuberculous. As the infant grows, more fat should be added to the food, and when the salivary glands develop, starch should constitute a part of the food. During the period of childhood, the diet must contain a large amount of nitrogenous food. The author holds the opinion that sweets, taken in the form of pure candy, are beneficial to the growing child if taken after meals. During the period of puberty, the harmonious development of the mind and body must be secured. When choosing a vocation, only such an occupation should be selected that will give the individual an out-door life the greater part of the time. He also refers to the necessity of securing the best hygienic surroundings. [F. J. K.]

9.—Salmon has contributed an article "on tuberculosis of animals in some of its relations to human tuberculosis." We are informed that in England and Wales, tuberculosis reached its maximum in 1838, when there were 17 deaths from phthisis out of every 100 total deaths. In order to demonstrate the importance of the study of the diseases of animals and the relation which some of these bear to

man, he makes reference to smallpox. This disease was at its height in England in 1796, when 18.5% deaths were due to smallpox out of every hundred total deaths. A hundred years later, in England and Wales, the death rate was as low as 1.8% per million living. Reference is made also to a number of very important statistics of tuberculosis in animals, only a few of which, we will mention in this abstract. In Prussia, 14.6% of the cattle and 2.14% of the swine were found tuberculous. In the city of Leipzig, 36.1% of the cattle, and 2.17% of the swine were tuberculous. In the State of Pennsylvania, over 2% of the cattle are tuberculous. Breeding animals and dairy stock are, as a rule, most frequently affected, while beef cattle are singularly free from tuberculosis. This disease appears to be more common amongst the better class of cattle than in the neglected, underfed-herd cattle. With swine, tuberculosis is a more acute disease, and shows a tendency to generalization, therefore there is more danger of transmitting the disease. He is of the opinion that there is little doubt that during the recent years, tuberculosis has been increasing in cattle and swine in most countries. The author is inclined to accept the view that animal tuberculosis may be communicated to man, and that the presence of tuberculous animals in a country must be regarded as a great source of danger. Our duty as sanitarians and citizens, is to use every possible effort to abolish this scourge. [F. J. K.]

10.—Chambers read a preliminary report before the Ontario Medical Society "on the relation of hyperchlorhydria to bilious attacks, some forms of gout, eczema, and muscular rheumatism." This author maintains that hyperchlorhydria may be responsible for diseases in other organs of the body. In his experience, he has found a close association between bilious attacks and hyperchlorhydria, he also examined the gastric contents of six cases of eczema, and in five of these there was an excess of HCl in the gastric contents. In the other cases the acidity was normal. He also records an examination made in a case of regular gout which revealed marked hyperchlorhydria. In conclusion, he states that he regards muscular rheumatism and hyperchlorhydria as frequently associated.

[F. J. K.]

11.—Williams believes that the gouty and rheumatic nature plays an important part in the etiology of many of the cases of acute and even chronic inflammation of the ear, and suggests that they receive proper constitutional treatment. [F. J. K.]

AMERICAN MEDICINE.

6. Carcinoma of the Breast. CARL V. VISCHER.
7. Peculiar Nervous and Urinary Manifestations Following La Grippe in the Aged. O. P. KERNODLE.

1.—William P. Spratling describes an ideal colony for epileptics and the necessity for the broader treatment of epilepsy. He groups the essential features of an ideal colony under: First, location, which will induce climate, water, soil, drainage, accessibility. Second, landscape improvements. Third, construction—general and special. Fourth, organization, administrative, medical and scientific. A diagram is presented showing a group of cottages at the Craig College for Epileptics, at Sonyea, N. Y.

[T. L. C.]

2.—L. A. W. Alleman reports a case of cerebral concussion, with retinal changes. The patient was a college athlete who went to his physician complaining of discomfort in reading, and blurring before the left eye. His corrected vision, which had been 20/15, was now reduced to 20/20 in the right, and 20/100 in the left eye. A change in glasses produced no improvement. The low vision of the left eye seemed to be due to a fault at the fixation point,

but a definite scotoma was not discovered. The ophthalmoscope showed, scattered about the fundus of both eyes, pigment spots which suggested old hemorrhages. The nerve margins were indistinct, and the retinal vessels tortuous. In the right eye, midway between the macula and disc, there was an area which showed pigment absorption and indefinite retinal changes; in the left there was a slight haze over the entire fundus. As there was no cause for this obstruction in the media, he considered it due to retinal edema. On the following day there could be seen a small fluffy spot just above the fovea which had evidently come on since the last examination. The case was finally found to be one of *commotio retinae*. At an examination made but a few days after the first, vision was normal and the patient's condition excellent. The etiology of this case revealed the fact that the boy had been struck in the head the day previous to his first visit, while playing a game of football, and had been temporarily "knocked out" for a few minutes. [T. L. C.]

3.—MacDonald discusses the advisability of total gastrectomy under the following heads: The diagnosis and age of the patient; the state of the blood; the heart; pre-existing conditions; metastasis; and preparation of the patient. He would limit the operation to 55 in men and 60 in women, excepting patients possessing extreme vitality. He says a stomach cancer may always be suspected in a person over 40 who exhibits progressive emaciation, lassitude, anorexia, with an absence of normal digestive leukocytosis, and the presence of the Boas bacillus. Leukocytosis tends to show that a metastasis or other complication exists, and therefore will indicate an unfavorable prognosis. The division of such important nervous structures as both pneumogastrics necessitates their inhibition and the heart gallops until the vagi have sufficiently recovered from the shock. The heart should therefore be in the best possible condition or life may terminate from cardiac shock. Workingmen and women offer a more favorable prognosis, while habitués of alcohol, tobacco, and other drugs, are decidedly unfavorable subjects. Syphilis, gout, diabetes, Bright's disease, and other debilitating and exhausting processes militate against success. The most favorable indications are a moderately dilated viscus with a freely movable tumor situated to the right of the median line. If the disease has existed for twelve or fourteen months it will hardly be suitable for operation. Metastasis is an absolute bar. To prepare a patient for gastrectomy MacDonald advises at least 4 to 6 days' rest in bed with most careful attention to the bowels, liver, kidneys, and skin. The stomach is washed out once in 24 hours with a mild antiseptic solution. Food should be given every two hours during the day and at least twice during the night; no solids are to be taken. The mental condition of the patient is also looked after. [F. T. S.]

5.—E. L. Shurly represents a statistical note concerning the contagiousness of tuberculosis pulmonalis. Of 130 cases reported, 16 have been immediately preceded by acute pneumonia, 22 by influenza, 12 by hemoptysis, with little or no antecedent cough, 1 by appendicitis. Several of the patients, it is noted, have had occupations which exposed them to metal, flour or other dust. Twenty-five have been preceded by acute or chronic laryngitis, or bronchitis, 11 by pleuritis, 9 by parturition, 2 by chronic uterine disease, 2 by measles, 1 by diabetes, 7 by syphilis and 3 by rheumatism, 3 by typhoid fever, 1 by empyema of antrum, one by suppurative otitis; 7 are recorded as having had large lymphatic glands, 3 were preceded by severe dyspepsia and diarrhea, 1 by psoas abscess, 1 by remittent fever, 4 by anemia, 1 by physical exhaustion. In 10 cases marked intemperance in the use of alcoholic liquors was noted. Sixty-five cases are recorded as having good family history and of the other 65 cases the parents were affected. In 12 cases brothers and sisters were affected, and in 58 cases some distant relatives had been affected also. With regard to the previous condition of these patients long before the development of the disease, it is reported that 76 were well and healthy, while 54 were delicate. Tubercle bacilli were recognized in 65 and absent in 52 of the series, and in 13 the result of the examination was considered doubtful. In 121 of the cases (eliminating the nine doubtful ones) there is a possibility of nine only having originated through ordinary natural communicability; while upon further analysis there is a possibility that 5 only so originated and further that of the whole number of

130, at least 112 were immediately preceded by acute or subacute disease. [T. L. C.]

6.—This paper emphasizes the already well-known facts concerning carcinoma of the breast, in order to draw attention to the early recognition of a tumor. It is suggested that every breast that has ever been the seat of inflammation be occasionally carefully examined. Of 56 cases operated upon by the author 36 1-3% died. Of those recovering 52% have passed the three years' limit. Over 81% were married. 3% occurred in women between the ages of 20 and 30, 10% between 30 and 40, 60% between 40 and 50, 13% between 50 and 60, 10% between 60 and 70, and 4% between 70 and 80. [P. T. S.]

This paper is by a homeopathic physician of Philadelphia. The author, however, gives little evidence in it of a homeopathic bias. His statements are clear and concise, and the subject matter is interesting. [T. L. C.]

7.—O. P. Kernodle reports three cases of peculiar nervous and urinary manifestations following la grippe in the aged. The nervous manifestations range from complete prostration to decided maniacal symptoms; the patient's condition counting for little or nothing. Independent attacks of grave urinary symptoms, appearing or reappearing with decided persistency, frequently leave a weakened system which is always sensitive to every change. He does not consider that post-influenzal insanity is a necessary complication of nervous debility attacking only those predisposed. Aged persons suffer more from la grippe than those in youth and vigor, and never entirely recover. Nephritis and urinary disturbances occur, and the death-rate is much higher than in persons not over 50 years.

2.—Will be abstracted when concluded.

3.—Passover relates the case of a recruit who presented a swelling of the ankle and, on the evidence of experts, was accused of simulating an injury to the joint in order that he may escape military service. After repeated examinations the man was adjudged guilty and sentenced to imprisonment in the military prison. The case was appealed, and the author called in as expert witness. He succeeded in demonstrating by means of the Roentgen rays the existence of an old fracture of the os calcis. The sentence was revoked. The author claims that by means of the Röntgen rays lesions may be discovered which are inaccessible to any other methods of examination.

6. A Case of Fibromyoma of the Walls of an Ovarian Cyst. V. E. ODINTSOFF.

1.—Kisel draws the following conclusions from an experience with 54 cases of tubercular peritonitis: 1. Tuberculous inflammation of the peritoneum in children is much more frequent than is generally supposed. 2. It may

be asserted that almost all cases of so-called idiopathic ascites are nothing else than tuberculous inflammation of the peritoneum. 3. The exudate in this affection is frequently absorbed under a general tonic treatment, and complete recovery ensues. 4. In the majority of cases it develops stealthily; the family, at first, notices only that the child is becoming emaciated and anemic without any apparent cause. 5. The diagnosis is considerably facilitated if a concurrent exudative pleuritis is found. 6. The thickening of the peritoneum (detected by grasping a fold of the abdominal wall) is one of the most valuable signs of tuberculous inflammation of the peritoneum. 7. In tubercular peritonitis, the fluid in the abdominal cavity is rich in albumin and of high specific gravity. Frequently the entire peritoneum may be found covered with recent tubercular masses, and yet the subjective symptoms may be insignificant. 8. The greatest difficulties in diagnosis are encountered in cases of chronic ascites dependent on tubercular pericarditis (a very rare affection). 10. In rare cases the onset of the disease is accompanied by acute symptoms. A number of illustrative cases are described.

[A. R.]

2.—Diterichs calls attention to certain peculiarities observed by him in the joints of persons who died of tubercular diseases. These consist in abnormal dilatation of the blood vessels of the synovial membranes and thinness of their walls. In these changes of the circulatory apparatus he is inclined to see an etiologic relation to infection with the tubercle bacillus. [A. R.]

3.—Will be abstracted when concluded.

4.—Liboff presents the views and observations of various authors on the influence of subaquatic occupations on the health of the workmen, such as bridge-builders, divers, etc. The conditions under which these men work are mainly those of increased atmospheric pressure, from 3 to 7 atmospheres being the usual limits. The effect of air under pressure depends on the degree of the concentration and the rapid changes from one atmosphere into another. The first effect of increased atmospheric pressure is on the ear. The person experiences pain in the ear, at first slight and then very severe; this pain may be communicated to the nose, jaws and forehead, and is brought about by the unequal pressure on the tympanic membrane. Sometimes the latter ruptures from undue stretching. The hearing becomes defective. The voice assumes a metallic resonance and is in some cases lost. The touch becomes benumbed. The mouth becomes dry, the cutaneous and mucous surfaces pale and the pupils dilated. The feeling of hunger supervenes, but thirst is never felt, owing to the increased moisture in the atmosphere. The intra-abdominal pressure is greatly lowered so that the abdominal wall falls in; on the other hand, the capacity of the lungs is considerably increased. The muscular strength is increased and with it the endurance. This, however, takes place only in the beginning of the work. The number of red blood corpuscles and the amount of hemoglobin are diminished, while the white blood cells are increased. This polkilocytosis may persist for a number of days. Generally, the effect of increased atmospheric pressure on man may be divided into two periods: (1) A period of exhilaration, lasting for about a month, and (2) a period of depression during which the appetite is lost and anemia, emaciation, indisposition to work and other evidences of depression supervene. The most important changes take place in the respiratory and circulatory apparatus. The number of respirations is lessened and the expiration is prolonged. Increased oxygenation of the blood takes place, so that the venous blood becomes red. The amount of CO₂ expired is increased. The pulse becomes slow and the heart's action is increased, leading in time to hypertrophy of that organ. The blood pressure is increased. The body temperature, if the pressure does not exceed 3 atmospheres, is at first increased. The morbid changes observed depend largely on the sudden ascent from a high into ordinary pressure. Under these conditions, hemorrhages from the ear and nose, hemoptysis, loss of sensibility, paralysis of the legs, bladder, large intestine, affections of the brain, unconsciousness and even sudden death have been observed. The paralysis may persist for a long time and finally terminate fatally. Excruciating pains in the joints and muscles are quite common, but do not persist, as a rule.

6.—Odinsoff reports a case of fibromyoma which was intimately connected with the walls of the cystic ovary, having been furnished by the blood vessels of the latter.

[A. R.]

BERLINER KLINISCHE WOCHENSCHRIFT.

June 24, 1901. (No. 25).

1. The Treatments of Obesity. E. STADELMANN.
2. The Decomposition of Albumin in Pernicious Anemia, Especially that Caused by the Bothriocephalus Latus. E. ROSENQVIST.
3. Vegetable Diet. ALBU.
4. The Symptomatology and Therapy of Appendicitis. KAREWSKI.

1.—The author discusses the methods of Banting, Ebstein, Oertel and Schwenninger for the treatment of obesity. He warns the profession regarding the dangers of the first method, which consists in the use of large quantities of meat and a slight amount of carbohydrates, on account of its injurious influence in cases of gout and renal disorders. Ebstein permits the ingestion of albuminous and fatty foods, but lessens the amount of carbohydrates, which the author believes is adaptable for milder cases of obesity. The method of Oertel, which has previously been advocated by Felix Hirschfeld, consists in cutting down the consumption of fluids. The latter observer's views are based upon his experience among the beer drinkers of Munich. The method of Schwenninger is practically the same as that of Oertel. [M. R. D.]

2.—Experiments on metabolism in eighteen cases of bothriocephalus latus anemia and three cases of pernicious anemia without a known etiology, showed that before the removal of the worm, an increased decomposition of albumin was present, while after the removal of the parasite albuminous metabolism was not as greatly affected. He regards this decomposition of albumin as due to some toxin produced by the worm. Even if the anemic processes are inhibited it cannot be said that the poison has been removed from the body, and in spite of the presence of the worm, there may be nitrogen retention. Rosenqvist dwells upon and urges the toxic nature of cryptogenic pernicious anemia. [M. R. D.]

3.—Albu opposes the older view that a vegetable diet is insufficient on account of its scarcity in albumin. For the healthy individual an exclusively vegetable diet is a very inconvenient way of ingesting food, not only on account of the large quantity that must be consumed, but on account of the undigested residue. But what is superfluous to the healthy individual may be of value to the sick one. Among the conditions that are benefited by a vegetable diet, are neurasthenia, neuroses of the stomach and especially hyperacidity of the stomach; also mucous colitis, chronic constipation, obesity, exophthalmic goitre, renal disease, and affections of the skin which are associated with disturbance of metabolism, diseases affecting the blood, or diseases of the gastrointestinal tract, such as pruritis, furunculosis, urticaria, erythema exudativum multiforme, and nodosum, as well as various forms of chronic eczema. The contraindications are gastric atony, gastrointestinal diseases due to anatomical lesions, and all conditions associated with malnutrition. It is to be added that many persons tolerate a vegetable diet very poorly, an idiosyncrasy, however, which is rare, and also occasionally occurs in other dietetic regimes. [M. R. D.]

BAUMGARTEN.

29.—Kukula reviews the literature of intestinal autointoxication, with a detailed list of the chemical substances which have been found as the cause. The experiments of many different authors and their results are quoted. Kukula, who has worked upon this subject for three years, divides his experiments into three series. In the first group he injected filtered intestinal contents from operated cases of intestinal occlusion into dogs, rabbits, apes, mice, guinea-pigs. Of these 39 animals, the great majority showed no reaction at all, probably because the material had been too much diluted. Of 14 other animals in whom artificial intestinal occlusion was performed, only one died of autointoxication. In the second series were 14 more experiments, in 7 of which Kukula succeeded in causing acute intestinal occlusion. Four of them died with typical signs of intoxication following occlusion. Injection of the intestinal contents were made in cats and dogs, and gave distinct symptoms of intoxication. The toxic substances found in the intestine are soluble in alcohol; this injected into animals will cause the symptoms of intoxication; and intraperitoneal will produce more serious results than subcutaneous injections. There are always fewer toxic substances in the small intestine than in the large. Pentamethylendiamin seems to play an important role in causing autointoxication. The third series of experiments consists of 30 animals in which the intestinal contents from five operated cases of intestinal occlusion were injected. Inoculations with the gases from the intestine did not always produce symptoms of intoxication. Mercaptan and sulphuretted hydrogen do not seem of much importance in causing intoxication. The same symptoms of poisoning reappeared in all the animals inoculated. These symptoms closely resembled those of autointoxication in man, from intestinal occlusion. Kukula believes that the vomiting is due to the intestinal intoxication. For when occlusion occurs, these toxic substances are formed, and as the epithelium is soon affected, they are easily absorbed. Then the symptoms of autointoxication soon follow. These substances are either dissolved in water, or they are absorbed as gases. Probably both processes occur. Kukula did not discover which substances were the exact cause of the autointoxication. [M. O.]

30.—Lorenz reports 158 cases of malignant tumors of the rectum which were operated upon in Albert's clinic in the past 14 years. In 105 others colostomy was performed; and 63 were not deemed operable. Thus 331 cases were observed in all, during 14 years. Colostomy was performed whenever radical operation was contraindicated, because the sacrum, bladder, or urethra was involved, or the cachexia was too great, etc. It was performed in three times as many men as women. Primary colostomy was only done in four cases. Kraske's dorsal method of operating was performed in 133 cases, the perineal method in 16 cases, and the vaginal method in two cases. 128 of the dorsal operations were for primary cancer of the rectum. The great majority of the operations were upon people from 40 to 50 years old. The coccyx was enucleated 42 times; the sacrum, or parts of it, removed 91 times. Of the former, three died; of the latter, 13; in all 17 deaths, only 12 of them from infection. The other five died from failure of the respiration, the heart, etc. Douglas' pouch was opened 79 times. The posterior wall of the vagina was resected 12 times, and divided once. The urethra and prostate were injured 8 times, four of them fatally. Twice the bladder was injured, both patients recovering. In 60 cases the rectum was amputated, with 13 deaths; in 25 it was resected, with 3 deaths; and it was drawn through in 17 cases, with one death. Of each of the latter groups, 8 regained control of their anal sphincters; 12 cases had absolutely no control. Kukula has heard recently from 100 of these patients. Of these 11 died soon after the operation, from the effects of the operation; 7 now have recurrence; 59 have died with recurrence; and 16 are perfectly well, an excellent result. [M. O.]

31.—Beely reports the case of a man of 17, who was born without a right hand. His hand had been amputated in utero. He could do anything with the stump, yet had an artificial hand made. He had marvelously well developed the muscles of the stump. The round end of the

radius lay just beneath the stump, as can be seen from the photographs and Roentgen photographs. The excellent use of the stump shows what may be accomplished in amputating or exarticulating a hand by operation. [M. O.]

32.—Bork has collected 24 cases of **tumor of the capsule of the kidney**, and gives their histories in detail. 20 were in women; 5 were in people over 50 years of age. In 15 cases the healthy kidney was excised with the tumor. Bork concludes that the tumors of the capsule of the kidney are **fibrolipomata**, **myxolipomata**, and rarely **sarcomata**. The former are benign, the latter malignant, while the myxolipomata are between the two. The kidney is always healthy. The operation for removal of the tumor is not considered dangerous nowadays. A table of the 24 cases collected follows. [M. O.]

33.—Payr describes in full two more cases of **old dislocation of the hip-joint**, in both of which **forcible, bloody, reposition was performed**. This makes five such cases reported by him. Kocher's incision for resection of the hip is made, that the muscles about the hip-joint may be protected as much as is possible. Care must be taken, when the force is applied, not to injure the soft parts about the hip. The different bandages and instruments employed in this procedure are given in detail. Extreme care of the wound is necessary, to prevent infection. Drainage should be left, after all hemorrhage is stopped and all injured tissue removed. In children the wound should be closed. Plaster casts and permanent extension apparatus are only needed when there is danger of the luxation recurring. One case out of the five died with infection. With passive movements and massage begun early, a good functional result is secured. In six weeks the patient can walk with the aid of a supporting splint. Photographs are given to explain the mechanism of the forcible reduction. [M. O.]

34.—For the past 10 years Barker has treated **fresh horizontal fractures of the patella by subcutaneous suture** with silver or aluminum-bronze wire. He makes but two tiny incisions. Very little anesthetic is necessary, as the operation only lasts from five to ten minutes, or local anesthesia may be employed. 21 cases are tabulated, with one death from delirium tremens. In three cases the sutures were removed two or three years later, because pain and an inability to kneel persisted. [M. O.]

35.—**Hyperemesis lactentium** is the name given by Schmidt to the uncontrollable vomiting in infancy, whether due to congenital stenosis of the pylorus or pylorospasm. Kehr and Loebker have done gastroenterostomy. Nicoll has lately dilated the pylorus successfully, a much less severe operation. An incision was made into the stomach, and the dilatation carried out from this. Schmidt reviews the literature of the subject in full, giving in detail the anatomical and clinical symptoms observed. He reports a case, a boy of nine weeks, upon whom dilatation of the pylorus was performed. The incision in the stomach was lengthwise, about 3 cm. from the pylorus. The pylorus was dilated at once with sounds, and the incisions closed. The child recovered rapidly, with no more vomiting. Schmidt believes that **pylorospasm is commonly the cause of this condition**, rarely a true hypertrophy of the pylorus. A table of statistics shows the normal diameter of an infant's pylorus, up to 10 years of age. Schmidt concludes that when medical treatment fails in these cases, the **pylorus should first be dilated**, up to the normal size according to the age of the child. Only if this fails should gastroenterostomy be performed. [M. O.]

36.—Payr reports a case of **acute suppurative orchitis**, probably due to mixed infection, as staphylococci were found, while there was a history of gonorrhea. The remaining testicle, in a man whose other testicle has been removed for abscess, was in turn full of abscesses. He recovered, after simple excision of the abscesses. The sexual function was in no way affected. His one testicle seems now to be in good condition, two years after the orchitis. In place of castration, the radical operation, Payr recommends **incision, with excision of the abscesses of the testicle and epididymis**. In this conservative manner, the sexual function is unaffected, and no severe operative shock is administered. [M. O.]

37.—In **tuberculosis of the testicle**, castration may rarely be necessary, as removal of the tuberculous mass, or excision of the epididymis alone will be enough. Besides, the process may have involved other parts, when castration will do no good. In 34 years at the Surgical Clinic in Tübingen 111 castrations were done, unilateral in 78

cases, in 33, bilateral. Of the 78 cases, 12% died of urogenital tuberculosis; 15% of phthisis; and 25% developed tuberculosis in the other testicle. Thus 46 were cured with unilateral castration. Of the 33 cases, 15% died of urogenital tuberculosis; 25% of phthisis; and 50% were cured with bilateral castration. When any other tuberculous focus exists, castration will be useless. The results of castration in tuberculosis of the testicle are far better than is commonly supposed. [M. O.]

38.—Baumgarten succeeded in causing tuberculosis to spread from the testicle to the vas deferens and prostate, but not in the opposite way, in his experiments upon animals never affected. The infection never traveled in a direction opposite to the excretory or secretory current. **Tuberculosis may appear primarily in the testicle**, as it does in the suprarenal capsule. Anatomical and clinical investigations bear out these experiments. [M. O.]

1.—Pfeiffer had noticed previously that typhoid serum lost its agglutinating properties when kept for a long time while the lysins were still well preserved. At Pfeiffer's desire Mertens investigated the condition of specimens of cholera serum which had been kept by Pfeiffer at room temperature for over five years. One which had been kept in a bottle which was completely filled, well stopped and sealed with paraffine, had lost some of its agglutinating property but protected animals still against cholera injections. Another which had been kept in a bottle which was only 1/3 filled and was not well stopped or sealed, did not agglutinate so well as the first and had no protecting power. A third bottle well filled and stopped and kept on ice, had lost none of its agglutinating or protective power. The serum in the different bottles was originally exactly the same and from the same source. This shows that the agglutinative and the immune bodies are affected differently by the same influence and Mertens shows that Pfeiffer is right in stating that they are different bodies. Mertens also reports some experiments which show that dead cholera cultures when injected intravenously produce a different degree of immunity from that produced when injected subcutaneously. [D. L. E.]

2.—The case was that of a 22 year old man who was taken suddenly ill with abdominal pain, vomiting and constipation. 24 hours afterward he was very comfortable but the vomiting continued later; he became cyanotic and very dyspnoic. The vomit became feculent though the abdomen presented no notable changes. The patient soon died in collapse. Since the right inguinal canal was wide open and a portion of the ileum about 10 cm. in length was bluish red and necrotic, the pathologist reported that the cause of the intestinal lesion was incarcerated hernia which had replaced itself. Bornhaupt admits that this may be a correct explanation, but inclines to the belief that the real condition was **probably embolism of the mesenteric artery** since the mesentery was suffused with blood in the region opposite the necrosed bowel. The mesenteric vessels were not carefully examined and it was not definitely known whether they were diseased or not, but Bornhaupt thinks that a large pleural hematoma which was found after death, and which had undoubtedly caused death might readily have been the source of an embolus which had produced the necrosis. [D. L. E.]

4.—In experimenting concerning the treatment of dysentery, Kruse found that small animals were so susceptible to fatal infection that it was impossible to produce an anti-serum with them, while large animals, probably because their susceptibility to infection was so very slight probably produced only an inactive and useless anti-serum. He injected

himself and his assistants with dead cultures, however, and obtained a very lively reaction in each case and the agglutinating power of their blood went as high as a dilution of 1 to 200, while it had previously been below 1 to 20. There is a possibility, therefore, of a specific treatment of dysentery but this possibility is not great and the older methods of treatment must be adhered to. Kruse is convinced from experimenting with the effects of various temperatures that the bacilli can live throughout the winter and that therefore there should be every effort to use careful disinfection and isolation and it should particularly be seen to that the sewers are good and are well flushed and that all houses have good sewer connections. Dysentery depends much more upon bad sewage than upon bad drinking water. Kruse has also investigated specimens of stools, as well as blood serum from a number of patients in insane asylums where dysentery was occurring in the epidemic form not uncommon in such institutions. He found a number of organisms which apparently caused the disease in different cases and none of these corresponded with his dysentery bacillus. The symptomatology is also different in this form of dysentery and Kruse consequently decides that it is not the same infection as epidemic dysentery, and is probably due to a variety of organisms.

[D. L. E.]

5.—Neubürger insists that angina pectoris is not the only result of coronary sclerosis. The symptoms develop gradually and angina pectoris is only one symptom. He divides the symptoms into three stages: (1) That of disturbance of sensation; (2) That of disturbance of motion; (3) Disturbance of nutrition. The first stage is usually evidenced by uncomfortable feelings, actual distress or severe pain about the heart and radiating to the left or sometimes to the right shoulder. These feelings usually decrease when the stomach is empty and increase after eating freely. The pain is present at first only after effort, but becomes spontaneous, the breathing becomes affected, and as the patient begins to show the second stage, the pulse becomes smaller, empty, frequent or perhaps infrequent and perhaps arrhythmic. The heart may show no changes upon physical examination. In the stage of depressed cardiac nutrition he emphasizes as very important attacks of asthma in persons not previously subject to it, and slight evening rises of temperature, or irregularities in temperature which he attributes to imperfect elimination of metabolic products as a result of imperfect circulation.

[D. L. E.]

6.—Other observers have reported attacks of eczema and various general disturbances as a result of the use of orthoform. Graul adds a case of eczema to the list. This was caused by applying an ointment of orthoform to a skin ulcer not more than a half inch in diameter for two days. The skin was however, unusually sensitive as the result of a previous severe irritation resulting from the use of hot applications. [D. L. E.]

June 20, 1901.

1. The Treatment of Pulmonary Tuberculosis with Tuberculin. GOETSCH, with a postscript by R. KOCH.
2. Physician, Apothecary and Patient. L. LEWIN.
3. Clinical and Therapeutic Investigations Concerning Pulmonary Phthisis. E. STADELMANN.
4. On the Treatment of Laryngeal Tuberculosis.

G. BESOLD.

1.—Goetsch reports his experience with tuberculin in the past ten years. This includes 224 cases, 12 died almost at once and 37 are still under treatment, hence he discusses 175 cases. 125 of these (71%) were discharged cured, the other 50 stopped treatment so soon that no results could be anticipated. 88 of the 224 had tubercle bacilli in their sputum. The average duration of treatment in the 125 cured cases was 198 days. The remarkably favorable results reported are to some extent explained by the absolute rule which Goetsch makes that only fever-free ("uncomplicated") cases are ever treated by him with tuberculin. He begins with a dose of 0.0001 mg. or if this causes reaction, 0.00001 mg. is used. If the latter also causes reaction he uses 0.001 mg. T. R. and after a dose of 0.1 mg. T. R. is reached he goes back to the old tuberculin and gradually increases the dose until if possible 1.0 g. is used at a dose. Reaction should never be produced, and the patient should always remain at rest for

24 to 48 hours after an injection. Koch adds a few complimentary remarks. [D. L. E.]

2.—Lewin begs the apothecaries to reduce their prices, particularly in dealing with the poor. [D. L. E.]

3.—There have been many contradictions in the reports concerning bacteriological investigations of the blood in phthisis. Stadelmann believes that those who have reported the frequent discovery of microorganisms in the blood in cases of phthisis with evidences of sepsis, have done so either because they have investigated the cases in the agonal period when a general invasion takes place, or because their methods were imperfect. Lasker, Stadelmann's assistant, found bacteria (staphylococci) in only one of 68 cases examined and that patient was in the agonal period. As to the diazo-reaction, he believes that it is of prognostic importance only when positive over a considerable period; it then indicates a bad prognosis even when the other signs apparently do not. Lasker examined 152 cases, only 38 of 69 cases of severe grade gave the reaction constantly. Hence a negative result does not mean a good prognosis, for of the 31 negative cases 15 died in the hospital. It also was often positive from time to time in mild cases. (To be concluded). [D. L. E.]

4.—Besold thinks that laryngeal tuberculosis should be actively treated but that if cases are well under observation and carefully watched, treatment may be postponed until general improvement of health or other factors are most favorable. If then the disease is advancing or there are tubercular tumors or ulcers with callous edges, he thinks active measures should be instituted even if the patient's condition in general is bad, though this does not hold if he is in extremes or has very advanced pulmonary disease. The most important point is to deal energetically with the disease and not stop half way. Partial measures do more harm than good. If lactic acid is used as an astringent the strength should be 20% to 30% and it should be applied well over the mucous membrane; if it is used as a disinfectant 50% to 75% strength should be used at first and often pure afterward, and the application should be distinctly a local one at the diseased area. The curette should be used to remove old granulations, etc. but the curette is often difficult to use for removing granulations on the vocal cords particularly, and Besold has devised a special pair of scissors for this purpose. He also discusses the use of the cautery, the occasional wisdom of laryngectomy and similar procedures, and particularly insists upon the necessity for rest of the larynx in any treatment of this organ. [D. L. E.]

19. A Case of Senile Chorea. BISCHOFF.

11.—Zollikofer has performed a number of experiments with the object of determining what effect irritation of the skin with tincture of iodine, mustard plaster, cantharidal plaster and croton oil has upon the number and relative proportion of the leukocytes of the blood, with the following results. When large portions of the body were irritated and blood taken from the finger, it was found that the number of leukocytes varied irregularly, and showed no relation to the irritation. Careful studies of the hemoglobin showed that it also was not affected, although it is possible that a slight diminution in the percentage was more frequent than any other change. Differential counts showed a slight increase in the mononuclear leukocytes.

and the same was true of the eosinophil cells. The blisters seemed to produce a more distinct effect. There was moderate increase in the number of leukocytes, with a slight increase in the polymuclear cells. Even Braunscheidt's method of local irritation with croton oil had no distinct effect. Finally Zolliker irritated a finger and then drew blood from it, and found that even under these conditions no distinct alteration occurred. In conclusion he calls attention to the very great variation in successive counts, and has found that these are not uncommon in perfectly healthy subjects. He does not believe that we are justified in concluding that the effect of local irritation of the skin is due to the modification of the blood. [J. S.]

12.—Grober has made careful studies of the amount of hydrogen sulphocyanide and particularly of potassium sulphocyanide in the sputum. He makes a quantitative estimation according to the following methods. Two ceca, of altered, fresh saliva are placed in a clean glass, a drop of acetic acid is added, and 3 drops of a .01 normal solution of chloride of iron. The mixture is then shaken, and if potassium sulphocyanide is present a red color appears. In order to determine approximately the quantity present he compares the resulting color with 3 standard solutions containing 2 mm., 1 mm., and 0.02 mm. The color in this solution is not altered in the course of 3 months. Quantitative estimations were made upon 100 cases. The substance was present in 82, but in 24 of these only the faintest trace could be discovered. He concludes that in nervous diseases it varies very considerably in quantity, in diseases of the blood-forming organs it is usually diminished; it is lost in malignant tumors, and diminished in cases of tuberculosis. He does not regard it as the product of the decomposition of the saliva, and his further investigations have shown that the quantity diminishes proportionately to the duration of secretion. It does not seem to be effected by nutrition, nor by the use of nicotine, even in persons not habituated. Small quantities of cuprous sulphite increase the secretion. [J. S.]

13.—Berlinger reports an interesting case. A man of 59, with an alcoholic history had had some swelling of the abdomen 2 weeks before admission to the hospital. The umbilicus became greatly distended. Three days before admission to the hospital there was sudden **puncture of the skin**, and several litres of yellow liquid were evacuated. When admitted he was prostrated, and upon physical examination a cirrhotic liver was readily felt. A small perforation was found in the under surface of the distended navel. The patient vomited blood several times, and finally died, apparently as a result of rupture of an esophageal varix. At the autopsy cirrhosis of the liver and tuberculosis of the peritoneum were found. The fluid contained erythrocytes and leukocytes. Sections through the skin of the navel showed it was involved in the tuberculous process, although no tubercle bacilli were actually found. [J. S.]

14.—Grassmann concludes his study of the **circulation in syphilis**, reporting in detail cases 81 to 96 inclusive. He also reports the results of a number of studies upon the hemoglobin, the blood pressure, etc. He concludes as follows. That as a result of investigations upon 288 persons in the early stages of syphilis, the normal function of the heart shows during the secondary periods of at least 23 of all the cases, disturbances that indicated either slight anomalies or distinct insufficiency. Arrhythmia occurs in about 85% of the cases, and subjective symptoms in nearly all. In the early stages of syphilis some impairment of the nutrition and functional activity of the heart muscle occurs, giving rise to weakness and dilatation, especially of the right ventricle. Exacerbation of a pre-existing chronic endocarditis may also take place. In nearly all cases the blood pressure is diminished, and it is increased by the administration of mercury. In the majority of cases of secondary syphilis the quantity of hemoglobin in the blood is diminished, rarely very considerably, and it improves very rapidly after the administration of mercury. Curiously enough in many of Grassmann's cases the percentage of hemoglobin increased after the first injection of mercury, which appears to be contrary to the doctrine upon which Just's sign is based. Grassmann does not believe that this change in the circulation can be ascribed to the sclerotic changes in the blood, nor to the action of the mercury. And he therefore ascribes them primarily to the action of the syphilitic infection. [J. S.]

15.—Ullmann, after a brief review of the literature, reports 5 cases that may be briefly given as follows. The first a man of 57 developed symptoms of general **septicemia**. The urine contained a considerable quantity of pus, and the patient finally died. At the autopsy an **abscess of the prostate** was found, due to infection with staphylococci and diplococci, secondary to an old specific urethritis. From this abscess thrombosis in the prostatic veins had occurred, followed by pyemia. The second patient, a man of 34, also had an abscess of the prostate due to infection with staphylococci. There were no symptoms of specific infection in the urethra, but Ullmann regards it as a case of prostatic infection. The symptoms resembled those of typhoid fever. The 3d patient, a man of 52, had suppurative prostatitis secondary to chronic specific urethritis which was the source of a pyemia. The 4th patient, a man of 55, had a phlegmonous inflammation of the prostatic tissue and plexuses, which was the source of the pyemia. There were no signs of gonorrhea. The 5th case, a man of 26, had severe chills 3 weeks after infection. There were pains in the limbs and joints, symptoms of acute endocarditis, and finally death. The nature of the general infection was not determined. [J. S.]

16.—Arnoth reports his studies of the blood and organs in a case of rapid, severe anemia, already reported by von Leube. The studies were made with exceeding care, and the different varieties of blood corpuscles described very accurately. The details cannot be given in a brief abstract. It may be mentioned that there were signs of an exceedingly active vegetative process in the red blood cells, chiefly evident in the normoblasts which were exceedingly numerous. In fact, all stages of blood from the first embryonal steps, to the finished corpuscle could be distinguished. The polymorphonuclear leukocytes were considerably diminished in number, and many failed to show granulations in smears stained with a tri-acid preparation. This accords with some of Ehrlich's observations. Transitional formations between the non-granular and the granular forms of leukocytes were occasionally found. Myelocytes were present to the proportion of 13.6%. A small proportion of them contained eosinophilic granules, the others, neutrophilic granules. The lymphocytes were considerably increased. Of the large mononuclear cells the large types of Ehrlich were present in about normal number. Studies were also made of the marrow and lymph glands. They showed considerable changes which, however, were not entirely identical with those of leukemia. An intravenous injection of the splenic pulp was made into a rabbit, but the animal died shortly afterward of pulmonary tuberculosis. [J. S.]

17.—Gildionsen has treated 12 cases of **pulmonary tuberculosis** by ordinary sanitary methods, of which 7 were greatly improved; 4 moderately improved, and one grew worse. Twelve cases were also treated by injecting **hetol**. Of these one was improved; 4 moderately improved; 3 not improved, and 4 grew worse. In only one of these cases increase in weight occurred. The author concludes that intravenous injections of hetol have no better effect upon the lung than the open air treatment, and on the other hand, may produce a distinct deterioration. The injections do not affect the fever; there is no improvement in the general condition; there is loss of body weight. The general results of the treatment are slight dulness or loss of sleep. There is no injurious local reaction, and laryngeal tuberculosis is entirely unaffected. [J. S.]

18.—Fraenkel has performed a number of experiments in order to determine what effect **cinnamic acid** has upon rabbits inoculated with tuberculosis. All the animals were inoculated into the eye, and then those selected for treatment regularly injected with the acid. No essential changes were found between those treated and those not treated, either in the amount of round cell infiltration, the size or extent of the tuberculous process, or in the general condition of the animal. None of the changes described by Landerer and Wüster as characteristic of the acid treatment, occurred. The lesion proceeded to caseation, tubercle bacilli were still found, and the process was steadily extending. [J. S.]

No. 19.—Bischoff reports the case of a woman 73 years of age, who had a left sided hemichorea of 5 years duration. The movements could not be controlled by the will; they ceased in sleep; there was considerable disturbance of speech, but neither paralysis nor disturbance of intelligence. The patient had apparently never suffered from

rheumatism, and the heart was normal. The characteristic features of the case were the peculiar movements of the head, from one side to the other, forward or backward in an irregular manner. The tongue was sometimes thrust forward, and then retracted, or rolled around in the mouth. The movements of the left arm and left leg were not nearly so frequent as those of the head and tongue; they occurred at intervals, and were rather sudden in character. The autopsy failed to reveal any essential lesion. There was some tuberculous degeneration of the spinal column at the junction of the dorsal and lumbar regions. Microscopically no essential changes could be discovered. The author has collected 68 cases from the literature, and concludes that senile chorea occurs with equal frequency in men and women. Rheumatism and heart disease are rare complications, and in about 60% of all cases intelligence is not disturbed. Usually both sides are involved. If it is unilateral there is apparently no essential difference. About 20% of the cases improve under treatment. [J. S.]

MUENCHENER MEDICINISCHE WOCHENSCHRIFT.

June 25, 1901. (No. 26).

1. Twenty-seven Intra-Cranial Resections of the Trigemini, Among Them 25 Typical Extirpations of the Gasserian Ganglion. F. KRAUSE.
2. Fat Embolism of a Tuberculous Lung, as a Result of Rupture of the Liver. H. ENGEL.
3. The Influence of Alcohol and Fruit Upon the Formation of Uric Acid. J. WEISS.
4. A New Vaporization Apparatus for Inhalation. A. BELLING.
5. Comparative Investigations Upon the Deficiencies of Various Inhalation Systems. R. EMMERICH.
6. Is there an Isolated Paralysis of the Cricothyroid Muscle? W. LUBLINSKI.
7. The Treatment of Leg Ulcers. WALBAUM.

1.—Krause discusses the operation for the removal of the Gasserian ganglion. The technique is as follows: A flap is formed consisting of skin, muscle, periosteum and bone, somewhat C-shaped, with the base just above the zygomatic arch. The initial incision is made through the skin and muscle down to the bone. A small perforation is then made in the upper portion of the flap piercing the skull, and another one anteriorly. A Gigli saw is then passed from one to the other, and the two incisions united. The two descending limbs of the U are then cut through in the same manner and the bone broken by means of an elevator. The fracture always takes place through the thinnest part of the bone in the temporal region. Resection of the arch of the zygoma is entirely unnecessary. It is very important that the vertical incisions should be carried down as far as possible in order to render it unnecessary to lift the brain from the floor of the skull for any considerable distance. The flap is then wrapped in sterile gauze and laid over the cheek, the middle meningeal artery tied in two places and cut. The brain is then elevated in the dura. Just to the inner side of the artery the three branches of the trigemini can be seen. The ganglion is then grasped in a pair of Thiersch forceps, the second and first branches cut at their respective foramina, and then the ganglion pulled out. In rupturing the first branch a very long piece is sometimes pulled out. The dangers of the operation are of course rupture of some of the large blood vessels around the carotid foramen. Krause has twice injured the cavernous sinus, and both times he was able to control the bleeding by packing. The duration of the operation depends largely upon the amount of hemorrhage and the time required to stop it. Usually it lasts about one and a half hours, but sometimes can be done in very much less time. When no effort is made to save the bone flap the operation can be performed much more rapidly, at least a quarter of an hour, and considerable blood are saved. One of the most important dangers is compression of the brain, although as a rule no characteristic disturbances are produced if tarboard spatula is used to lift it. Occasionally the dura is excessively thin and friable, and this renders the operation more serious and difficult. [J. S.]

2.—Engel reports the case of a man suffering from pulmonary tuberculosis, who, during a morning walk, in an

attempt to save himself from a fall, fell on his body sharply backward and to the right. He felt severe pain and was obliged to sink to the ground. In about 10 minutes, however, he was able to go on with his walk. The following morning he had difficulty in breathing and was very restless. In the afternoon he died. The right lung showed excessive edema, and the left partial collapse as a result of pleural adhesions. A rupture was found in the liver, and an examination of the liver substance showed considerable fatty infiltration, with the exception of the cells in the immediate neighborhood of the rupture. Sections through the right lung showed that nearly all the capillaries were filled with fat droplets, and Engel regards these as coming from the liver cells in the neighborhood of the rupture. This fat he believes was liberated by pressure, and he regards it as the immediate cause of death, although the extensive tuberculosis of both lungs probably contributed to the fatal result. [J. S.]

3.—Weiss has made some studies upon the influence of alcohol and fruit upon the excretion of uric acid in the urine. He found in one case that the administration of 5 of a litre of cognac produced no effect upon the quantity of uric acid, although the quantity of urine was considerably increased. The administration of 8 lemons appeared to produce a very slight diminution. The administration of 860 grms. of apples with the peels caused a sharp diminution in the quantity of uric acid that lasted for 2 days. He regards this as due to the slight amount of citric acid in the apple peels, and considers that this acid is more efficient than the various other remedies hitherto used in the treatment of uric acid diathesis. [J. S.]

4.—Bulling describes an ingenious apparatus which consists essentially of a large tank into which 2 sets of tubes are passed. One contains a small apparatus for vaporizing liquids, and the other consists of a number of long tubes with openings in their ends, whose size can be determined. Through the latter compressed air escapes into the room. This when dry has a tendency to become saturated with the moisture of the vaporized liquids, probably by preventing the formation of large drops. It can be warmed or cooled according to wish. [J. S.]

5.—Emmerich has performed a number of experiments for the purpose of determining the size of the drops and their number after the vaporization of liquids, and the depth to which they pass into the respiratory apparatus. The work was performed chiefly with the apparatus of Bulling. He finds that this apparatus provides for the saturation of the atmosphere with moisture more rapidly than any other hitherto constructed; 3 to 4 minutes sufficing to reach 100%. The drops remain minimal in size. Their diameter varies from .006 to .012 mm. The smallest were the most common. Comparison of various other instruments results greatly in favor of Bulling's apparatus. He found that in one minute 11,000 drops fell upon the space of 1 sq. cm., whereas by other forms not more than 3000 drops were deposited in the same space in the same time. The apparatus was constructed of 2 open bottles connected by a system of tubes, and it was found that with Bulling's apparatus the liquid penetrated more deeply than with any other. The author is, however, sure that they never penetrate as far as the alveoli, because experiments upon the lungs of men that had been executed showed them practically free from germs. [J. S.]

5.—Lublinski discusses the symptoms that can be produced by isolated paralysis of the cricothyroid muscle. He found that in all probability the voice would be deep; that the high notes would be imperfect and that all tones would be rough and impure. The vocal cord on the affected side would probably be slightly wavy in outline, and it is possible that the opening between the 2 cords would be slightly oblique, although this symptom has not yet been observed. He has, however, observed conditions in 1 case that lead him to believe that the anterior cricothyroid muscle was paralyzed, the case in each instance being preceding attacks of diphtheria. [J. S.]

6.—Walbaum upholds the use of camphor for the treatment of leg ulcers. His method is as follows: He first uses a mixture of clay and acetic acid for a dressing, until the discharge becomes slight and odorless. Gauze soaked in spirits of camphor is then applied; over this a layer of dry gauze, and finally some rubber or silk protective, and the whole enclosed in cotton wool and a bandage.

Every second day the dressing is changed, and on these occasions the edges of the ulcer are well rubbed, and the surface cleared of any adhering membrane until the granulations stand out clearly. [J. S.]

ZEITSCHRIFT FUER ORTHOPAEDISCHE CHIRURGIE.
1901. (Volume 9, No. 1).

1. Dr. Felix Schenk. WILHELM SCHULTHEISS.
2. Description of Scoliosis in a Young Pig.
WILHELM SCHULTHEISS.
3. Three Cases of Congenital High Position of the Scapula. WILHELM RAGER.
4. The Treatment of Severe Scoliosis.
CARL DEUTSCHLAENDER.
5. Ikonometry, a New Method of Measuring Scoliosis.
ROBERT GRUENBAUM.

1.—A eulogy of the late Dr. Felix Schenk.
2.—Schultheiss describes in full a specimen of scoliosis in a young pig. The preparation shows the occurrence, in the pig, of a scoliosis resembling that seen in man. The scoliosis is dorsal, convex to the right, with a twisting of the anterior and posterior parts of the vertebrae. There is also some torsion and lateral deviation of the spine and of the separate vertebrae, showing that the epiphyses of the bodies of the vertebrae have grown together. The bodies of the vertebrae are broader on the concave side, even where there is no scoliosis. These peculiarities are well illustrated by a series of photographs. [M. O.]

3.—Rager describes three children with congenital high position of one scapula. The first case was a girl of 8, whose right arm was injured at birth. She uses her right arm somewhat, but does almost everything with her left. The right shoulder is much higher than the left. Measurements showed that the right scapula was smaller in all dimensions than the left; the right side of the thorax was less well developed than the left; and the right arm was shorter and smaller than the left. A Röntgen photograph showed a difference of 3 cm. between the positions of the two shoulder-blades. Active movement of the right shoulder is almost impossible, but passive movements can be freely made. Electrical reactions were normal, and the pressure of one hand equalled that of the other. Special exercises of the right arm and hand have improved the condition. The other two cases, boys of 6 and 8, are very much alike. The difference between the position of the scapulae was 6 cm. and 8 cm.; both had inguinal herniae, adenoids, deformity of the upper edge of the smaller scapula, etc. In all three cases the condition was congenital, in the first case associated with injury at birth. The deformity of the scapula in the second case may have been due to fetal rickets, in the last case, where an echondrosis existed, to disturbed position. The intellect of the last two patients was markedly below normal. Exercises were begun, and the parents told to wait several years, when the children could themselves decide for or against operation. Movement was possible in both cases. Rager found in the literature 30 cases of unilateral high position of the scapula, and two bilateral cases. The majority were on the left side. He divides the cases into four groups: (1) those with torsion of the axis of the scapula; (2) those without change of axis, yet with exostosis-like lengthening of the upper inner corner; (3) those with true bony connection from the atlas to the inner edge of the scapula; and (4) simple high position of the normal scapula, the great majority of the cases. Rager concludes that a high position of the scapula was the primitive condition; and that its descent, in these cases, seems to have been hindered by some abnormal connection with the vertebral column. [M. O.]

4.—All but the most severe forms of scoliosis can be benefited by time, apparatus, energy; yet only in the few, especially favorable cases will the deformity disappear. The position of the spinous processes of the vertebrae in scoliosis is now plainly to be seen upon Röntgen photographs. Nowadays the diagnosis of the grade of the scoliosis is not difficult. Operation, immobilization, gymnastics, redression, and fixation of the spine, with apparatus, have all been advanced as treatment. The plaster jacket applied in extension is the best apparatus. It should be worn at least two or three months, changed two or three times, and followed by gymnastics. Besides, the treatment should extend over two years, the after treat-

ment, for years longer. Those cases which come under treatment early, will benefit most. If growth has stopped, or is very slow, the prognosis will be poor. It is especially favorable from 5 to 7 years, and again at puberty, the time the bones grow. Both patient and physician must have patience, as the whole procedure takes time. The correct treatment must be ordered, depending upon the pathological anatomy. Then the case must be carefully watched for years. For changes in the internal organs will result from high-grade scoliosis. [M. O.]

5.—Grünbaum describes his new method of measuring scoliosis. For this he uses the ordinary photographers reflex-camera. The mechanism of the camera-lucida is used, so that the outline of the body, the position of the scoliosis, and the curves can be drawn on paper, one quarter the natural size. It is simple, inexpensive, and can be used by the general practitioner. The child has only to stand up for a few seconds. [M. O.]

Band 45, Heft 5 and 6.

1. Contribution Concerning the Action of Antiarin.
HEBDOM.
2. The Effect of Antiarin on the Isolated, Suspended Frog's Heart. STRAUB.
3. The Effect of Carbonic Acid on the Isolated, Suspended Frog's Heart. STRAUB.
4. Investigations Concerning Acidosis in Diabetes Mellitus and Acid Intoxication in Diabetic Coma.
MAGNUS-LEVY.
5. Concerning the Preparation of the Digitalis Glucosides and their Composition. CLOETTA.
6. The Manner in Which Poisons which Excite Convulsions Cause Reduction of Temperature.
HARNACK AND STARKE.

1, 2, 3.—The first three articles, all from the Pharmacological Institute of Leipzig, refer to the action of antiarin and its relation to the action of carbonic acid. Hebdom gives an unusually elaborate series of references to the literature concerning the "Hydra-Tree of Death" and the action of its active principle, antiarin. This is an exceedingly active cardiac poison, less than 0.00023 per kilo of body weight causing death in frogs, a little more killing cats, and 1 mg. proving fatal in rabbits. Pigeons were less susceptible to its action. It increases the energy of cardiac systole, produces marked cardiac action and in fatal doses the heart ceases beating in firm systole. The substance was recovered from the hearts of poisoned animals. Neufeld has already stated that when the heart's action had been stopped by antiarin hydrocyanic acid would cause it to beat again and to continue its contractions. This Hebdom has confirmed, the hydrocyanic acid causing the heart which had ceased beating in complete systole to relax and slowly to begin beating again and to continue thus and vice versa, hearts stopped in diastole by hydrocyanic acid began beating again after the use of antiarin; the susceptibility to antiarin was much reduced by the previous use of hydrocyanic acid. The latter acts upon the nerves and muscles while antiarin influences the muscles directly, producing by direct action severe fibrillary tremor and rapid decrease of the muscular irritability and final loss of the latter. Its action was not closely similar to that of veratrum-antiarigenin, a product of antiarin, is like the digitalis group in its action, but its action is weaker than that of antiarin. Straub, as a résumé of his paper states that the action of antiarin is different upon different portions of the heart, decreasing from the ventricle toward the sinus. It causes continued decrease of the irritability of the heart cells, the contractions becoming prolonged and slow, the time between auricular and ventricular contraction becoming prolonged and leading finally to permanent systole. As a result of his second work, Straub decides that carbonic acid causes weakening of the cardiac conditions and their final cessation, and he believes that this action of carbonic acid should be considered in all cases in which one would investigate the effects of any substance which can paralyze respiration. It differed completely from antiarin in effect, in that the latter did not influence the energy of cardiac contraction while carbonic acid largely reduces it. [D. L. E.]

4.—Magnus-Levy begins his article by describing a num-

ber of interesting chemical methods, the most striking of which was one by means of which he isolated oxybutyric acid from the urine of diabetic patients. His most important chemical statement, to the chemists at least, is that after precipitating diabetic urine containing oxybutyric acid with lead, the reading of the polariscope was much lessened. This may be true of urines that contain no oxybutyric acid also and at any rate it shows that the usual method of reckoning the amount of oxybutyric acid by determining the difference between the results obtained by polariscope and titration is very subject to error (and thereby, the determination by polariscope of the amount of sugar is more subject to error than is commonly thought.) He reports a new case of diabetic coma (in a child of 12) which was successfully treated with alkalies (by the mouth) 219 grammes having been used in two days. The coma was typical and lasted from one morning into the next day, and then slowly vanished completely and there had been no suspicion of coma for two months at the time of the report. The free use of alkalies caused marked increase in the acid output. Magnus-Levy has previously insisted that excessive destruction of body albumin is not a necessary accompaniment or predecessor of diabetic coma—contrary to most writers, particularly the older ones, he states that such albumin destruction cannot usually be demonstrated. In this case, as well as in others which he has seen, there was absence of pathological albumin destruction. He also reports three other cases of diabetic coma treated with alkalies, all of them ending fatally. He considers the presence of oxybutyric acid an absolutely constant accompaniment of severe diabetes, basing this statement upon the experience of Naunyn and others and upon his personal discovery of the acid in every one of 29 cases. Some authors have claimed that there was great disturbance of intestinal digestion and absorption in diabetic coma, but though the patient who recovered from coma had colicky attacks, there was nothing abnormal about the stools, and of the large doses of soda given by mouth about 99.5% was absorbed. The study of the nitrogen in the feces also showed good absorption. The use of large doses of alkalies during coma or in acid intoxication without coma, causes a very marked increase in the excretion of acids, as shown by the fact that the urine remains acid unless enormous doses of alkali are used: Magnus-Levy shows this even more convincingly by the figures which he obtained in estimating the acid output (oxybutyric and diacetic) under these circumstances. He puts the question whether the coma is really an acid intoxication primarily, or whether the acid intoxication is largely a secondary matter and the urinary evidences of it to a considerable degree, at any rate, the result of therapeutic measures (use of alkalies.) He answers this by stating that in coma there is not only a much larger production of acids, there is also a marked reduction in the capacity of the organism to oxidize these acids, as strongly evidenced by the marked reduction in the alkalinity of the blood (Kruse and Magnus-Levy). The coma is, therefore, an acid intoxication and must now be generally admitted to be such. The occurrence of coma depends upon the relative acids. Magnus-Levy then refers to Sternberg's theory that diabetic coma is due to B-amidobutyric acid. In the first place this theory is an improbable one because the amido acids so far found in the human organisms are of the *alpha*, not the *beta* series, and further, analysing the figures in the case here, reported as terminating successfully. Magnus-Levy concludes that there was not sufficient break down of nitrogenous tissue to explain the production of the amount of oxybutyric acid which he found, and which according to Sternberg, would be obtained from amidobutyric acid. This shows it is impossible that this theory is correct and it also shows the impossibility of the direct production of action from albumen; the latter may possibly occur indirectly through partial decomposition and subsequent synthesis, but certainly not by direct decomposition and oxidation. There are only two further possibilities—production of the acids from fats or through synthesis. The former is already quite thoroughly demonstrated to occur; the latter Magnus-Levy considers also a probable method. [D. L. E.]

6.—Harrock's experiments lead him to conclude that picrotoxin had much less marked influence in reducing the temperature of older rabbits than of the young. The effect is due to peripheral vascular dilatation and probably also to some extent to reduction of heat production. [D. L. E.]

CENTRALBLATT FUER INNERE MEDEZIN.

July 20, 1901.

On the Relation Between the Bile and the Production of Hippuric Acid in the Animal Organism.

S. ROSENBERG.

Rosenberg has investigated the validity of the conclusions recently reached by Zimmermann (abstracted from *Centralbl. f. Innere Med.*, 1901, No. 22). The latter decided that his work showed that when bile was absent from the intestine that benzoic acid no longer produced hippuric acid in the organism through synthesis with glycocholi, and that the latter substance is produced from glycocholic acid after its absorption from the intestine. As was to be expected, Rosenberg offers strong proof that these conclusions were at least too far-reaching and probably essentially incorrect. He made a gall-bladder fistula in a dog and allowed the bile to discharge through this, preventing the dog from lapping up any of the discharged bile. Probably no bile reached the intestine, and at any rate dog's bile contains but traces of glycocholic acid, if any. Yet the urine of the dog contained hippuric acid in considerable quantity after administering benzoic acid, while none was found when benzoic acid was not given. There was not the faintest evidence of absorption of bile into the circulation, so Rosenberg decides that Zimmermann's conclusions were not justified; and since he finds that Kühne and Hallwachs had performed his experiment with the same result nearly fifty years ago, and that Bunge and Schmiedeberg showed that the injection of benzoic acid is followed by hippuric acid synthesis in frogs, even after extirpation of the liver, he believes that the bile cannot be the only source of glycocholi. [D. D. E.]

CENTRALBLATT FUER CHIRURGIE.

July 6, 1901. (28 Jahrgang, No. 27)

1. The Topography of the Vermiform Appendix.

P. MUELLER.

1.—While ordinarily the appendix is easily found, it is sometimes very hard to discover. From experiments in operations and upon cadavers, Müller has found that the appendix always rises from that point upon the cecum where the three descending mesenteric bands join one another. Thus by following the anterior broad band, down the cecum, through adhesions, exudates, etc., the appendix is invariably discovered. [M. O.]

WIENER KLINISCHE WOCHENSCHRIFT.

June 6, 1901. (XIV Jahrgang, No. 23).

1. The Diseases of the Bronchial Lymph-Glands.

FRIEDRICH SCHLAGENHAUFER.

2. The Physiology and Pathology of the Gastrointestinal Action. JULIUS WEISS.

3. The Static Relation of the Human Skeleton.

CESARE GHILLINI and SILVIO CANEVAZZI.

1.—Schlagenhauser, who has found two cases already reported, of suppurative of the bronchial lymph-glands in pyemia, reports three cases observed by him. All three cases occurred in young girls, and ended fatally in a few days, with the symptoms of a purulent meningitis. Autopsy revealed multiple cranial abscesses in all three patients with perforation and subsequent meningitis in two of the cases. In each case the infection started from a suppurative bronchial gland, under the bifurcation of the trachea, opposite the right bronchus. The infection entered from the esophagus. All three cases were probably tuberculous, also. Schlagenhauser suggests that these suppurative bronchial lymph-glands may explain many of the cases of so-called brain abscess. [M. O.]

2.—After reviewing Pawlow's experiments upon the digestive tract, Weiss reports his own experiments in dogs. Incision into the stomach and small intestine a half hour after eating shows the meal as yet absolutely undigested, but the lymph-vessels, which are ordinarily too small to show, are found enlarged and dilated, ready for absorbing food. He has found that small quantities of albumen, given before meals, has a good effect when the gastrointestinal function is disturbed. Somatose for instance, causes lymphofluxion and lymphostasis. This also explains the post-digestive leukocytosis which is observed. Weiss concludes that the lymphoid tissue has an exceptional influence upon gastrointestinal action. This begins just as soon as

the food reaches the stomach even while the intestine is at rest empty. This action will explain some of the gastrointestinal disturbances which are relieved by the administration of astringent and the bitter tonics. [M. O.]

3.—In this article, full of quotations from the works of the late Professor Albert Gaillini and Canevazzi discuss the effect upon the rest of the bony skeleton of deformity, especially due to pressure. To support the weight of the body, a compensatory deformity of other bones often can be found. Thus with genu valgum, the tibia often changes in form. The authors claim to have established this in their works, already published. [M. O.]

June 13, 1901. (XIV Jahrgang, No. 24).

1. Suppuration in Human Beings Without Bacteria. KARL KREIBICH.
2. Atresia With Double Vagina. J. HOFBAUER.
3. A Case of Reflex Cough From a Foreign Body in the Ear. MAX BREITUNG.

1.—From recent experiments by many investigators, it is plainly established that chemicals will cause suppuration in animals without the presence of bacteria. In man it seems that the use of catgut sutures, or that superficial injuries, caused aseptically, may be followed by suppuration. Kreibich experimented upon men affected with eczema, using sterile croton oil injections. Abscesses followed, without bacteria in 61 cases, with cocci in only six cases. This showed that suppuration could occur in man without the presence of bacteria. Both in animals and in man, suppuration may be the reaction to the irritant of chemicals. Investigators have shown that suppuration is only a certain stage of inflammation, not a separate qualitative form of inflammation. The literature of the subject is reviewed and quoted, the experiments of Kreibich being given in detail. He shows that the serous effusion in blebs bullae becomes purulent without the presence of bacteria. Kreibich concludes that in normal circumstances suppuration may occur in man without bacteria. [M. O.]

2.—Though cases with double genitalia are no longer seldom in women, Hofbauer reports a case of atresia with double vagina. A woman of 33, married at 20, had been ill since marriage. During and after coitus she complained of great pain, mainly on the left side. Operation, for ante-flexion and stenosis of the cervix uteri, revealed a septum dividing the vagina, with a cavity behind it, the rest of the vagina. It was on account of this inner vaginal cavity that the outer vaginal walls seemed so small. Similar cases are quoted from the literature. [M. O.]

3.—After a brief review of the subject, Breitung reports the case of a boy who had coughed a long time in paroxysms, with a tickling sensation in the larynx. The cough was very severe; and no cause for it could be found. Finally Breitung discovered cerumen impacted in his ear, which was softened and removed by syringing. While doing this he caused severe attacks of coughing. After the ear treatment was stopped, the cough disappeared, nor has it returned in the three years which have passed since. Breitung believes that this is a frequently undiagnosed cause of reflex coughing. [M. O.]

NEUROLOGISCHES CENTRALBLATT.

June 16, 1901. (No. 12).

1. The Tract of Helweg. H. OBERSTEINER.
2. Contribution to the Knowledge of the Course of the Fibres of Taste. J. KRON.
3. Reply to the Criticd Remarks of R. Klenböck Upon My Article: "Contribution to the Symptomatology of the Triple Disturbances in Syringomyelia (Osteomalacia)." S. S. NALBANDOFF.
4. Reply to the Above Remarks. R. KLENBOECK.

1.—Obersteiner having recently had a case in which Helweg's tract was degenerated, and desiring moreover, in reply to some criticisms of von Bechterew, has prepared a brief article as an addition to his previous longer one in the publications of his laboratory. The case was one in which a tumor was found in the floor of the 4th ventricle springing from the right side. It involved the whole of the upper portion of the right half of the medulla, compressing the olive. The degenerated fibres could be traced by the Marchi's method in the peripheral portion of the lateral bundle just back of the point of admission of the anterior roots. They first appeared in the upper level of the dorsal portion of the cord, increased slightly in number in the cervical region, and were most numerous in the 2d cervical

segment forming a small triangular group in the characteristic region of the tract of Helweg. The lower end of the olive was completely surrounded by these fibres. They then separated into 2 groups, one lying dorsally and one ventrally. Their further course could not be positively determined. It seems likely that this degeneration was produced largely by the pressure of the tumor in the area dorsal to the olive. Obersteiner calls attention to the fact that the position of the fibres is not infrequently atypical. [J. S.]

2.—Kron reports the following interesting case of syphilitic meningitis. A man, 25 years of age, noticed for a year a gradual depression in the right temporal region. Subsequently pain developed, spreading from this region to a point beneath the clavicle. There was some tenderness on the left half of the head, complete atrophy of the temporal muscles. The right cheek was also atrophic, and there was complete ptosis on the right side. All the muscles supplied by the facial nerve were normal. The left eye seemed to be retracted, and there was slight commencing ptosis on the left side. Hearing was normal. The clm reflex was not affected. There was anesthesia and analgesia in the right half of the face, anterior to the ear. There was slight diminution of smell on the right side, and apparently slight diminution of taste on the right side of the tongue, with the exception of the anterior 3d of the posterior portion where taste was completely lost. Otherwise the patient presented no symptoms. Although syphilis was denied, the patient was given antisyphilitic treatment and recovered the use of the right eye, and general improvement occurred in all the other symptoms. In particular taste returned completely, and became equal on both sides. The lesion appears to involve the motor root of the 5th, and then the 3d, 4th and 6th nerves, and to a slight extent, the sensory root of the 5th. The case appears to prove that the fibres involved are largely derived from the 5th nerve. [J. S.]

3.—Nalbandoff, in his reply to Klenböck, insists that the decalcification of the pharyngeal bones, is a form of nutritive disturbance that has hitherto been unknown, and he believes that it is impossible to escape the belief that it bears some relation to chronic phlegmonous inflammation. [J. S.]

4.—Klenböck insists that partial decalcification is by no means uncommon in severe inflammatory disease of the fingers. [J. S.]

1. The Central Terminations and Unions of the 7th and 8th Cranial Nerves. N. WYRUBOW.
2. The Pathological Anatomy of Basedow's Disease. Preliminary Communications. L. KEDZIOR and J. ZANETOWSKI.
3. The Question of the Connection Between Dreams and Hallucinations. D. KAZOWSKY.

1.—In a brain of a case with complete right-sided peripheral paralysis of both facial branches, as a result of caries in the temporal bone, Wyrubow was able to determine the following points. First, degeneration of the root could be traced to the nucleus on the same side, and slight degeneration to the nucleus on the opposite side. Secondary changes were found in the ganglion cells of the nucleus on the same side, and in the cells of the contralateral nucleus. These secondary changes were also found in a hitherto undescribed nucleus which was situated at the level of the reticular nucleus of the pons, and the approximate portion of the nucleus of the same side, and from the nucleus of the abducens and the inner side of the facial nucleus. This consisted of cells of the motor type, resembling those of the facial nucleus. He names it the "accessory" or "upper nucleus of the facial." Immediately after their entrance into the brain the fibres of the cochlear nerve enter the ventral nucleus of the acoustic tubercle, and then passing around the restiform body they send fibres into Deiter's nucleus and into the descending root of the acoustic nerve. Other fibres pass into the trapezoid body and some cross the raphe and become contralateral. The degeneration fibres of the vestibular nerve pass into Deiter's and Bechterew's nuclei, and a certain number of them form a sharply circumscribed column that passes under the floor of the 4th ventricle to the opposite side and terminates in the contralateral internal nucleus, and Deiter's nucleus, the greater number, however, terminate in Bechterew's nucleus in the opposite

olive. There are more degenerated fibres on the opposite side than on the same side as the lesion. Descending degeneration can also be traced in the reticular substance in the medial nucleus of Burdach's column, and some cross the raphe and terminate in the opposite lower olive. Other fibres group themselves in Goll's column. As for the ascending degeneration, it could be traced into the lateral lower fillets. Toward the posterior corpora quadrigemina, the degeneration fibres become less numerous. Beyond this they could be followed to the accessory nucleus of Bechterew of the oculomotor. No degeneration was found in the acoustic fibres of Monakow. [J. S.]

2.—The patient, a girl of 18, had had symptoms of **exophthalmic goitre** for about 4 years. She died of croupous pneumonia. At the autopsy there was hypertrophy of the thalamus, dilatation and hypertrophy of the heart; cyst of the right ovary, and obstruction of the left Fallopian tube; numerous recent and old hemorrhages were found in the medulla. The left testiform body was smaller than the right, but otherwise the central nervous system was entirely normal, with the exception of the testiform bodies in the upper portion of the medulla, and considerable asymmetry of the middle and lower parts of the same portion of the brain. [J. S.]

3.—The patient, a boy of 16 years, had murdered his teacher, and was referred to Kazowsky for the purpose of determining his mental responsibility. There were numerous stigmata of degeneration; the reflexes were much exaggerated; there was a history of scrofulosis with suppuration from the eyes and ears. He had been capable, although with difficulty, of mastering his lessons, but was unable to advance in the gymnasium. While in one of the lower schools he had a severe attack of scarlet fever followed by nephritis, but apparently recovered completely. Three weeks after he returned to school he committed the crime. He had always been peculiar, and solitary; had never been irritable or violent; but had been fond of blood-thirsty literature. There was a distinctly neuropathic heredity. From the age of 12 he had been addicted to onanie, and from the age of 13 had been an alcoholic. He himself stated that although he was not unfriendly to the teacher, he had suddenly conceived the idea of killing him apparently as a dream in which he had had a quarrel with him. He apparently was entirely oblivious of the consequences of his act. Immediately after the murder he became partially unconscious. It appeared that the patient had physical and psychological degeneration, although his intelligence was fairly good. He was a poor mathematician, and apparently had little active perception. The paper is still unfinished. [J. S.]

BOLNITCHNAIA GAZETA BOTKINA.

(June 6, 1901. (Vol. XII, No. 23).)

1. On the Biology of the Blood. V. F. VELIAMOVITCH.
2. Contribution to the Biology of the Looferment.

V. N. OBUNEFF.

3. A Case of Acute Glanders. E. FLERINA.
4. A Case of Priapism. P. I. GUNDEGGER.

1.—Veliomovitch ridicules the theory that the alkalinity of the blood has anything to do with the predisposition to or causation of disease, or that the alkalinity can be raised or lowered at will by the administration of alkalies. The human organism, he maintains, is not a test tube in which various chemical reactions may be instituted by the chemist. The blood is a living tissue possessing a definite chemical composition which cannot be varied at liberty, nor can the blood be acted upon apart from the organism, and any benefit derived from iron or alkalies is due to the systemic effect of these drugs. Moreover, the alkalinity of the blood, as proven by Orlovsky, depends entirely on the red blood corpuscles and is subject to variations even in health. [A. R.]

2.—Will be abstracted when concluded.

3.—Flerina reports a case of **acute glanders** in a man, 37 years old, a horse dealer by trade. The affection was characterized by a generalized pustular eruption, dry pleurisy, dulness over both lungs and evidences of pyemia. Several hours before death a secretion appeared from the nose. Neither the clinical symptoms nor the pathological findings were such as to make a diagnosis positive. The latter was established by a bacteriological examination which proved the presence of the bacillus mallei. [A. R.]

4.—Gundegger observed a case of **priapism** in a man 45 years old. The patient had an obscure pneumonia at the

termination of which the erection of the penis appeared and persisted for 4 weeks despite treatment. There was no previous history of a similar affection or venereal disease. The organ was painful at the root and directed towards the left. The author ascribes this condition to **sclerotic changes in the cavernous bodies**. A number of cases are cited from the literature showing the connection of priapism with leukemia. [A. R.]

LA PRESSE MEDICALE.

June 19, 1901. (No. 15).

1. Muco-membranous Entero-colitis of Uterine Origin. HENRY REYNES.
2. Epidural Injections by Sicard's Method. M. BROCARD.

1.—After reviewing the numerous causes of **muco-membranous entero-colitis**, Reynès states that it must be regarded as a symptom of many conditions. But of these conditions he believes inflammation of the uterus and adnexa to be the main cause. In looking over the literature of the subject, he found that not only do ligaments and adhesions exist between the ovary and the intestines, but both lymphatic and blood vessels show communications also. He believes that the entero-colitis is but one of the catarrhal symptoms produced by a number of causes, generally in the female, in connection with inflammation of the uterus or adnexa. Therefore local gynecological treatment will be necessary, and warm vaginal douches, enterocolysis, also baths will prove of benefit. [M. O.]

2.—Brocard reviews the work done upon **epidural injections**, and the discussions upon this proceeding of Sicard's heard at the various society meetings since. The injections should be made in the triangle just below the spine of the last sacral vertebra, and above a line joining the two spinous processes. A large quantity of fluid can be injected: it travels high up the cerebro-spinal canal; it is absorbed by the epidural plexus; vaso-constriction occurs; and there is some direct action of the cocain. As a rule 2 cc. of a cocain solution, 1 to 100 or 1 to 200, are used. The patient may lie upon one side, in the Trendelenburg position, or in the genupectoral position. The needle is introduced 4 or 5 cm. The place to be punctured is difficult to find in stout people. Only a feeling of heaviness about the kidneys or in the buttocks follows the injection. The pain of the pricking is felt three or four hours later and persists till the next day. No fever, nausea, headache, etc., occurred. All pain disappeared five minutes after the injection, and only reappeared three or four days later. This method has been successfully employed in treating sciatica, lumbago, herpes zoster, intercostal neuralgia, and the crises of tabes. As a means of producing analgesia, it has failed signally. Medically, especially therapeutically, it seems to be of great service. [M. O.]

JOURNAL DES PRATICIENS.

June 15, 1901. (15me. Année, No. 21).

1. Picric Acid in the Treatment of Gleet. H. DE BRUN.
2. The Nature and Treatment of Buccal Leucoplasia.

PAUL COMBALAT.

1.—The desiccating action of picric acid in moist skin affections, and the rapidity with which epithelium is regenerated under its influence, caused De Brun to employ picric acid in solutions of 1 to 100 or 1 to 200, in treating anterior urethritis. Urethral injections are given one to three times a day, and usually cause a cure in 4 or 5 days. Leukocytes and gonococci rapidly diminished in number. A number of case-histories of acute and chronic anterior urethritis are given in full. The results are excellent. It does no good in posterior urethritis. De Brun also uses it in treating balanoposthitis. [M. O.]

2.—**Buccal leucoplasia** is a chronic condition in which the mucous membrane of the mouth is covered with white spots, some of which are desquamating. There is generally some ulceration. The main predisposing causes are syphilis, gout, rheumatism, etc. Leucoplasia sometimes is the point of origin of carcinoma. Caustics must not be used in treating leucoplasia; nor is any local treatment generally beneficial. Diet, hygiene, relief for constipation, alkaline waters as a mouth wash, no indulgence in smoking, or in alcohol, etc. are needed in the treatment. A salicylic or chromic acid wash may do good after the affection has become chronic. Finally curetting or the thermocautery may be used to remove the leucoplasia. [M. O.]

British Congress On Tuberculosis

Continued from Page 309.

State and Individual Prophylaxis of Tuberculosis During Childhood and the Need of Children's Sanatoria.—Dr. S. A. Knopf, New York. In the first portion of the paper the author refutes the conception of frequent hereditary transmission of the bacillus tuberculosis, and demonstrates that post-natal infection is virtually the only source of tuberculosis in infancy and childhood. He describes the manner of how the child in the home of an unclean, ignorant or unscrupulous consumptive has multiple chances of taking the disease into his system by inhalation, ingestion and inoculation. The contraction of tuberculous cows, is also briefly treated. The precautions which should be taken to avoid the infection of the child from tuberculous parents and others living in the family are described in detail, and so are the kind of instruction-leaves concerning the prevention of tuberculosis which health boards should gratuitously provide to physicians, midwives and mothers. The author's views concerning the so-called hereditary predisposition are set forth, and may be summarized here by saying that there is inherited very often from a tuberculous mother, much more rarely from a tuberculous father, a physiological poverty, which may handicap the offspring in its development, and offers, when occasion presents itself, a suitable soil for the invasion of the bacilli of tuberculosis. Dr. Knopf is, however, convinced that many of these children, born "tuberculisable," could be protected from contracting the disease by being placed from early childhood in proper sanitary surroundings and given a prophylactic, hygienic and dietetic treatment. Respiratory exercises for the development of the lungs are, in the opinion of the author, of great importance in this prophylactic treatment. The hygienic and dietetic treatment should, however, begin with the mother while the child is still *in utero*. The most healthful life, generous diet, comfortable garments, and breathing exercises in the open air, should be prescribed for the mother during the state of pregnancy. The duties of the State and municipality in the prevention of tuberculosis in children are outlined and the urgent need of children's sanatoria, to which schools should be attached, for tuberculous and scrofulous children is dwelt upon.

On the Notification of Tuberculous Diseases in Norway. By Dr. M. Holmboe, of Norway. According to the law of May 8th, 1900, which law came into force January 1st of this year compulsory notification of such cases of tuberculosis, which are accompanied by secretions, has been introduced in Norway. These are subject to notification: (a) new cases of such disease coming under medical treatment; (b) deaths of persons suffering from such disease; (c) change of residence of such persons, if so determined by the municipal council and approved by the Government. The notifications are to be sent to the local officer of health, who in Norway is always a physician; these notifications have a confidential character. Compulsory notification has been introduced in order to give the officer of health an opportunity of seeing that necessary cleanliness is observed in the homes of the sick, especially in the treatment of their secretions, and that a radical cleansing is made of their rooms and garments and bedclothes, before others make use of them. The law has been too short a time in force to allow any definite statement to be made with regard to its effects. At any rate, no complaint against inconveniences resulting from the compulsory notification has yet come to the notice of the directorate of the medical service.

Wet Winds and Phthisis. By Dr. William Gordon, of Exeter. In a paper read last November before the Royal Medical and Chirurgical Society on "Wind-Exposure and Phthisis" (published in the *British Medical Journal* of January 12, 1901), an endeavor was made to show that exposure of a district to west and southwest winds in Devonshire entailed a relatively high rate of phthisis amongst its inhabitants. To this conclusion numerous objections were raised. The object of the present paper is to meet

those objections. A single rural district (Okehampton) has been chosen—inland, elevated, of simple geological structure, having a population which may be regarded as uniform in respect of sanitation, closeness of intermarriage and race (one parish only being doubtful as regards this last), and free from occupational phthisis. Deaths amongst females only have been considered. The period of observation has been ten years. It is contended that ten years is a sufficient period and that the small figures are an argument in favor of and not against the accuracy of the conclusions. On examination of the parish death-rates from phthisis amongst females it is found:

- That the distribution of this death-rate cannot be accounted for by soil or rainfall, sunshine or purity of atmosphere; and differences of sanitation, occupation, race, or intermarriage do not exist to explain it.
- It cannot be ascribed to the influence of the north, northeast, east, or southeast winds, nor, except in slight degree, to the northwest wind.
(The south wind is the only wind which does not affect the district).
- It can be largely accounted for by the influence of exposure to the west and southwest winds.

The paper is illustrated by maps and tables of figures.

A Note Bearing on the Statistical Evidence of the Extent of Heredity in Tuberculosis. By J. Edward Squire, M. D., London. In 1894, in a paper before the Royal Medical and *American Medical Journal* (November, 1897) I gave reasons for considering that the influence of direct heredity in consumption is not so great as it was at that time believed to be. Although about 33 per cent. of consumptives present family history of tuberculosis, I showed statistical grounds for attributing the disease to occupation and surroundings in by far the greater number of these cases, and placed the possible influence of heredity at about 9 per cent. instead of at 33 per cent. Within the last few weeks I have had occasion to look through a number of life insurance claims, and incidentally I have abstracted some figures bearing upon the influence of heredity at tuberculosis. Of 469 claims in which the required information was available, I find 78 deaths from consumption and other forms of tuberculosis, of these 78, only 7 had any history of consumption in the family; 22 other cases in which death took place from causes other than tuberculosis, gave phthisical histories. We have thus 140 cases free from consumptive taint, of whom 71 died of tuberculosis, 16.13 per cent.; and 29 cases with consumptive family history, of whom 7 died of tuberculosis, 21.13 per cent. The excess in the percentage of deaths from tuberculosis in those with a consumptive family history over deaths from this disease in those without direct hereditary predisposition (viz., 8 per cent.), is curiously near to the figures (viz., 9 per cent.) which I arrived at in my *Medico-Chirurgical* paper to express the influence of heredity in tuberculosis. The number of cases dealt with in this note is too small to be of much value by itself, but is interesting as tending to confirm the opinion, now very generally accepted, that the direct influence of heredity in tuberculosis is considerably less than was formerly supposed.

Cure of Tuberculosis by Francisque Grötte's Treatment. Report by Dr. Albert Salivas. 1. Recapitulation of communications made at the International Congress held at Paris in August, 1900, on the cure of tuberculosis by Francisque Grötte's treatment. 1. Scientific basis of this method.
2. Clinical observations.
3. Conclusions.

On Time-Saving Methods of Treatment, with a Preliminary Note on the "Silver Treatment" of Phthisis by Intravenous Injections of Protargol. By Wm. Ewart, M. D., Cantab., F. R. C. P. It is now recognized that phthisis is curable by open air if sufficient time be allowed. Our next effort should be to shorten the cure, and this communication is an endeavor to promote the search for more expeditious methods, without which the complete realization of the scheme of State-aided relief cannot be carried out owing to the vast numbers to be dealt with and to the costliness of the necessary accommodation and of the treatment and

diet. Much, therefore, would have been achieved if the individual stay at State sanatoria should be shortened; and this achievement is claimed as possible if the cases of phthisis (excluding always hopeless cases) were to be provided with adequate preliminary treatment such as to fit them to secure from sanatoria the maximum good in the minimum time. Quite recently strong claims have been put forward in favor of various methods of treatment. Special notice would seem to be due to those with pretensions as "specifics," most of which probably do some appreciable good, even though not fulfilling their entire promise. A strong plea must therefore be entered in the interest of the rate-paying public as well as of the patients for an adequate inquiry into the comparative capabilities of the various "cures" now available. It is clear that we cannot rest satisfied with our present system, however great its advance upon previous conditions.

The "Thorough Treatment" or "Hospital Treatment" as a preliminary to Open Air or Sanatorium Treatment.—Early and mild cases in strong subjects are practically self-curable with an open-air life; but with the large group of pyrexial, sub-pyrexial, or more or less chronic phthisis, the open-air treatment, at any rate in this country, and also the climatic treatment, so it would seem from Alpine experience, is not the shortest way to a cure. Nay, many cases are at first ill-suited for it. In these cases progressive tuberculosis is perpetuated by the catarrh. A great deal of the latter is remediable by what may be termed the hospital treatment, or "thorough" treatment, the object of which is to rid the case as soon as possible of its dangerous complications—bronchitis, catarrh, caseation, and suppuration—whilst utilizing the period of unavoidable confinement in bed, in the ward, or in an even temperature, for the application of every therapeutical influence which in the individual case may be profitably resorted to. This idea has been recently carried out with an encouraging degree of success in a limited number of cases. The favorable results obtained have demonstrated to my satisfaction the advantage of not sending the patients to the open air prematurely, but only in a convalescent state.

The Direct Pulmonary Methods including the Intravenous.—In addition to serum therapy, which belongs to the future, these include the *intratracheal injections*, which are not sufficiently recommended by their results,—the *inhalation treatment*, well known to all in its more familiar applications, but specially elaborated into definite methods by Cervello with only partial success as the formaldehyd system, and more recently with every promise of practical usefulness by Dr. George Stoker as the *continuous nasal oxygen inhalation method*; and, lastly, the *intravenous injections*, which in some form, perhaps quite different from any at present in use, are likely to prove the most active and rapid agency. *Lauderer's sodium cinnamate treatment* has had a fair trial, and the bulky injection method which we owe to Dr. Maguire's labors is now being tried. I am not acquainted with the latest development of the *formaldehyd injection treatment*, but some of the results obtained with the original method were very favorable, although neither by this nor by any other method has a permanent clearance of the bacilli from the tissues been obtained. I was lead to substitute *protargol* for formaldehyd by the conspicuous success of the administration of nitrate of silver in pneumonia (Caccianiga) and of its subcutaneous injections in phthisis (Mays). Pending the discovery of some better remedy I have provisionally adhered to it in preference to formaldehyd because of its more decided, of its more rapid, and of its more lasting action. The clinical effects resemble those obtained by Dr. Maguire with formaldehyd—viz., a remarkable subjective feeling of improvement coinciding with manifest improvement in aspect and in strength, a rapid diminution in the cough and in the expectoration, and a more or less rapid change from the dense sputum of phthisis to simple catarrhal sputum and ultimately to hyaline mucus, etc. The ultimate effect is to lower the temperature, but meanwhile the level may be disturbed by elevations incidental to the treatment. More often than not the injection is followed after one hour by a chilliness or even a rigor and a sharp rise lasting about half an hour. After this has passed off the patient feels and continues to feel remarkably well; no untoward symptoms of any kind have followed the rigors. A short attack of nephritis occurred in one patient, but this seems to have been occasioned by a chill. Pre-existing al-

bunuria of long standing was much reduced in one of my cases; in another the first injection succeeded in stopping rebellious hemoptysis.

The Technique.—The details of the operation are given in the paper. The injection consists of 10 cubic centimetres of saline solution containing $1\frac{1}{2}$ to $2\frac{1}{2}$ grains protargol, and this is preceded and followed by an injection (through the same needle) of a few cubic centimetres of pure saline solution to obviate leakage of irritating fluid into the tissues, which is apt to lead to considerable pain and swelling. From twelve to fifteen injections generally suffice. It is best to administer them at intervals of one day, but in some cases they have been given daily.

The Systematic Treatment.—The protargol injection method has yielded by itself satisfactory results, but it does not claim to be more than the first and most important instalment in an extensive system of active treatment. My present practice is to combine with it, as soon as the case has lost all acuteness, general massage, gentle exercise, and particularly respiratory exercise for the expansion of the lung, strong diet and nutrient adjuncts, local and general treatment of the skin, and suitable internal remedies, among which I have obtained specially good results from ichthyol, originally recommended by Wertheimer. This combined treatment, a full description of which cannot be briefly given, has enabled some patients with originally unfavorable prognosis to become, after a few weeks' stay in the hospital, quite suitable for the open-air treatment, and to return, after a short period in the country, greatly improved, and with a promising forecast of ultimate recovery.

Drugs may have been too much discouraged owing to the superior virtues of "open-air." Our knowledge of the latter should not paralyze, but stimulate our therapeutical activity. A place is still to be found for the old remedies, not any longer as the sum of our treatment, but as useful or necessary adjuncts. Expectorants, antipyretics, tonics, and sedatives may all have their temporary uses. But there are new remedies from which greater help may be derived, particularly when judiciously combined. Good combinations have been sacrificed to the desire to prove any one system to be a specific cure. The *continuous inhalation of oxygen* for instance, is compatible with various hygienic helps, and with most useful forms of medication. The same is true of the *hyper-nitrogenous alimentation* advocated by Richet (raw meat treatment) and by Harper (urea treatment).

Wertheimer's Ichthyol treatment consists in the administration after meals of a few drops of ichthyol, say, in peppermint water, with a daily increase of one minim till ten minims are taken—some of my patients have taken twenty minims with advantage. A diminution in the cough and expectoration, and a change in the character of the sputum are perceptible in a few days. My own experience endorses Wertheimer's most encouraging reports, and for the present I have no hesitation in recommending ichthyol as the remedy which will most favorably and most rapidly influence the catarrhal complication, even when administered singly. But this or any other medicine found to be superior may be used in combination with intravenous injections; and it is my belief that such a combination would help us to effect a rapid change in the condition of the lung and to subdue the catarrh sometimes within two to four weeks, and thus pave the way for a rapid improvement under the "open-air" treatment.

Conclusions.—In this system of treatment there is nothing final. On the contrary, all its details are provisional and merely the best that existing opportunities afford. Its results, hitherto, seem to justify a hope that yet better things are in store, and that well-sustained efforts in the direction indicated will, at no distant date, bring about a considerable reduction in the total duration of the cure of phthisis, and in the minimum period to be spent at sanatoria. The cases treated have all been hospital cases, and therefore illustrate the possibilities open to the State for the treatment of phthisis among the poor on a considerable scale, if Poor Law Infirmarys and Sanatoria were thoroughly organized for carrying out a well-conceived systematic treatment. In all its details, and in special connection with the intra-venous injections, the general scheme which has been proposed could be more easily conducted at public institutions than in private. So long as no better remedies are forthcoming those which have been suggested may be used with safety and profit; but it is urgent, in

view of the important issues at stake, that a systematic enquiry should be undertaken into the comparative value of the various forms of treatment elaborated by individual efforts, and for some of which important claims have been advanced.

What are the Means Employed by the Different Nations of Europe to Combat Tuberculosis? What are the Means Which it is Necessary to Apply Generally upon the Basis of an International Agreement? By Dr. Samuel Bernheim. In order to study the actual state of this question the author has communicated with several colleagues in various countries of Europe, and most of them have replied. In certain countries absolutely nothing or very little has been done.

In other countries the "sanatoria" system or the anti-tuberculosis dispensaries system are or have been in vogue, with the application of sanitary laws. All these means are excellent in their way, but insufficient. In fact, intercourse between the different nations is to-day so great that international contagion is unavoidable.

To accomplish a result, successful and efficacious, which would be useful in all countries, it would be (according to Dr. Bernheim) necessary to have an international agreement or understanding, which would define the remedies to be generally applied. This has always been carried out for plague, cholera, and yellow fever. It would therefore be necessary that doctors of every country (at least, those of Europe) should agree among themselves to memorialize their respective governments to nominate a permanent anti-tuberculosis committee or commission, and to furnish it with powers to dictate prophylactic measures and to rigorously supervise their application.

Sterilization and Pasteurization vs. Tubercle Free Herds, Etc. By E. W. Hope, M. D., M. O. H. One of the dangers of the tuberculous infection of human beings arises from the consumption of raw milk taken from cows which are themselves suffering from tuberculosis—notably tuberculosis of the udder. The object of the discussion which I have been asked to open is to determine which of three methods suggested furnishes the most practicable and the best safeguard against this danger, always bearing in mind that, if we decide to rely upon one, and are in a position to apply it with certain effect, we shall not necessarily exclude the others, unless we can be assured that in doing so, we are not, whilst effecting security from one danger, discarding safeguards against others even more serious.

It is obvious that numerous points are involved in the subject, some of which are difficult to dissociate from questions other than those which concern tuberculosis only. For example, measures taken with the sole object of checking an even more destructive form of disease, viz., diphtheria, have proved incidentally a safeguard against tuberculosis, whilst, on the other hand, measures directed against tuberculosis have afforded a valuable protection from other forms of disease.

We must look at the subject from the wide view of general sanitation, remembering for the moment that there are other evils to be conquered as well as tuberculosis, and also bearing in mind that communities, like individuals, in their efforts to free themselves from mischief may be doing harm to those of their neighbors who are less able to take care of themselves. In the remarks that I am about to make and for the purposes of this paper, I shall take it for granted that the phrase "properly cooled between the time of milking and the time of reaching the consumers" implies also cleanliness, and all other sanitary requirements except those specifically directed against tuberculosis, and furthermore my observations will be restricted to those aspects of the subject which most concern the large centres of population.

The term "Sterilization" and "Pasteurization," so far as the subject under consideration is concerned, have practically the same significance, viz., raising the temperature of the milk to a degree which is capable of destroying the tubercle bacillus; exposure to a temperature of 170° to 180° Fahr. for about twenty minutes to half an hour is sufficient to destroy most pathogenic organisms. However, sterilization and pasteurization of milk possess one conspicuous advantage, viz., that the application of the safeguard is within the reach of every reasonably prudent and

careful household, consequently for ease of application it is beyond any comparison with the other preventive measure to be considered. The objections to it do not appear to be important, but there are the facts to be reckoned with that in the lower quarters of every great town there are thousands of families neither prudent nor careful, and also that the population of this country as a rule prefer to take their milk raw. This preference results, no doubt, partly from thoughtlessness and partly from habit. Young children are trained to take it raw, and the belief is widespread that if the milk is raised in temperature to, say 200° Fahr., or even still nearer to the boiling point, it is altered in flavor and constitution, and is of less nutritive and digestive value than when it is given raw; the raw milk, in fact, is regarded as more nearly approaching the natural milk of the mother.

There is no chemical evidence whatever to show that sterilized or even boiled milk is less nutritive and valuable than raw milk. On the other hand, cows' milk raw, in addition to the risk of tuberculosis, brings many others. The process of milking may involve dirt from a dirty milker, from dirty udders into a dirty milk pail. From this it may be passed through a dirty strainer into a dirty railway can. It is discharged from the railway-can into smaller vessels in which it is hawked about the dusty streets, passing through some half dozen other pots and pans before it reaches the nursery or the table of the consumer, involving a host of possible sources of contamination, not excepting the contamination of tubercle bacillus; in fact, it may be safely said there is no article of food in common use so constantly exposed to contamination or so susceptible of contamination as raw milk. The milk, on the other hand, as Nature intended it to be given, is never once exposed to air, passing directly and at the time of its manufacture, in the gland to the stomach of the young animal, and, apart from the possibility of disease in the gland, is bacteriologically clean and pure.

Sterilization, valuable as it is as a final safeguard against tuberculosis, is after all only an expedient, and must not be put into so much prominence that the importance of the other safeguard is lost sight of, although we cannot take it for granted in considering the merits of different methods that essential accessories common to them all will be observed. The one merit of sterilization is that it is an expedient easy of application and presenting few administrative difficulties. Beyond any question the ultimate advantage lies in obtaining the milk from herds free from tuberculosis. It is in fact comparable with the advantage of obtaining drinking water from a pure source instead of taking it from a contaminated one and relying upon purification afterwards. The first aim must be to ensure that the source of the milk is pure, in other words that the cows are free from tuberculosis; or if this, under existing conditions of the law and public opinion is unattainable, that they shall at least be free from any tuberculous disease of the udder or any tumor or condition of the udder simulating tuberculous disease, or, having regard to difficulties in diagnosis, we may with advantage go even a step further and demand that the udder is all cows from which milk is taken for human food shall be in a perfect normal condition.

The main causes of tuberculosis in cows are notorious: close confinement in ill-ventilated, badly-lighted, ill-constructed cowsheds—defects all as easy to remedy as is removal from the cowshed of the obviously tuberculous animal before it can cause infection of the rest.

In the City of Liverpool about 25,000 gallons of milk are consumed every day; one-half of it comes from cows (about 600 in number) kept within the city, the other half comes from cows kept in the country, and is sent in by rail. Within recent years that part of the milk supply which comes from cows kept within the city has been practically free from tuberculosis. This has been brought about by the sanitation of the cow sheds, adequacy of air, light, and cleanliness, by systematic and frequent inspection of the cows by qualified inspectors with veterinary help, by frequent bacteriological analysis of the sample of milk; these are the measures which have effected this end. I do not say that out of the 6000 cows in the city there is not a single one affected with tubercle, but merely that there are few with such form of tuberculous disease as would be likely to contaminate the milk supply.

These methods and this system of inspection were not

initiated without difficulty and opposition. There is no opposition now; every person acquiesces in advantages which have been gained. But there is another aspect to the question. Only one-half of the quantity of milk consumed in Liverpool is supplied from the city, the remaining half comes from the country districts. But surely, you will say, if the cows kept in the cowsheds within a great and populous city are healthy, those coming from the sunny meadows of the country, with their fertile pastures and ample land, are free also. Unfortunately experience does not bear this out; the milk sent in from the country is more frequently tuberculous. Thus, out of 422 town samples examined during 1899 and 1900 five were tubercular, being slightly above 1 per cent.; but out of 490 country samples taken during the same period twenty were tubercular, being a trifle over 4 per cent. How can we protect ourselves against this? A special Act of Parliament applying to a few great towns, including Liverpool, gives special powers to exclude from the city, under a penalty, the milk coming from the country cowsheds in which tuberculous cows are kept under dirty and unsanitary conditions. But if it is difficult to deal with and supervise the supply within our own city, it is evidently both costly and difficult to maintain a staff to send, under the special Act of Parliament, to the insanitary and tubercular cowsheds of the country cowman; but, having overcome these difficulties, the broad national question comes in, for although we succeed in protecting ourselves what happens with regard to the diseased cows and the diseased milk? The dealer refrains from sending diseased milk to the protected city, but what is there to prevent him from sending his milk for sale and consumption to a district where no special Act of Parliament exists to enable the community to protect itself, or from selling his diseased cows to a dairyman in another locality. This is not the way to secure a supply of milk from herds free from tuberculosis, but there can be little doubt that the action of the great cities will not only protect themselves, but will to a certain extent protect the country districts also, and will strengthen the hands of rural sanitary authorities. No doubt the great cities are financially better able to protect themselves; they have their larger and more costly staff, they have their bacteriological laboratories, their veterinary and medical officers, but at best they are but valuable allies to the rural sanitary authorities, and these after all must take their own action, since the protection the cities afford them is an indirect vicarious one, and, as in cases which I have alluded to, there is nothing to prevent the cowkeeper from sending his diseased produce to rural districts after he has been prohibited from sending it to great cities. Furthermore, the undoubted decline in the proportion of tuberculous milk sent in from the country may really mean that a larger proportion is consumed elsewhere. The subject is quite important enough for a government department—*v. n.*, the local government Board—to take in hand and appoint a special staff to supervise the milk supply and all appertaining to it throughout the country.

I have no hesitation whatever in saying that it is quite possible to insure that the milk supply shall come from cows free from tuberculosis. Difficulties from ignorance, obstruction, and active opposition may be taken for granted, but these must be overcome, and the cowkeeper will learn in time that his own interests are identical with those of his customers, and by keeping healthy cows in a sanitary condition he will be a gainer in every way.

It is only right to say that during last year samples of milk taken at the railway stations on arrival from the country do not appear to be more frequently tubercular than the samples taken from the town.

This may indicate one of two things: either a general improvement in the country cowsheds under the stimulus of city action, or, as in more cases than one which have come under my notice, dairymen who have been detected in sending in tuberculous milk have refrained from sending milk to Liverpool, and now send their milk elsewhere. These points are not to be lost sight of.

Frequency and Significance of Tuberculosis of the Tracheal and Bronchial Glands in Miliary Tuberculosis of Children and in Tuberculous Meningitis. By P. Haushalter, of Nancy, and A. Fruhinsholz. In 78 autopsies of miliary tuberculosis in children below 12 years of age,

tuberculosis of the tracheal and bronchial lymphatic glands was met with 71 times (about 95 per cent.); in 67 cases there was tubercular meningitis, and in 64 of these affection of the glands was present. This glandular affection has always the character of an old and caseous tuberculosis; in 29 cases it coincided with old tuberculous lesions of the lung, generally localized; in 41 cases it formed the only old tuberculous lesion present. In almost all cases, therefore, the origin of the bacillary infection which ends in the miliary form and in meningitis, is in caseous tracheal and bronchial glands. The frequency of this lesion is a proof of the importance of aërial contagion of tuberculosis in children. How does this tuberculous affection of the glands, which is more developed and deeper-seated in the miliary than in any other form of tuberculosis, end in the bacillary infection of the blood, which is considered almost the sole cause of the miliary form and of the meningitis? In spite of the intimate relations of the vessels at the base of the heart with the masses of caseous mediastinal glands we have failed to find, macroscopically or microscopically, any lesion of the walls of the vessels that could explain the direct passage of the bacilli from the lymphatic glands into the blood. The bacillary infection of the blood takes place through the lymphatic system; in the very brief time occupied by the passage of the bacillus-bearing leukocytes from the caseous lymphatic glands of the mediastinum into the blood stream, passing as they do by the efferent lymphatics, and by a short section of the thoracic duct or of the great lymphatic trunks—the destruction of the bacilli has not time to be effected. Even in many of the cases in which pure meningitis exists, without generalized miliary infection, and in which one would therefore be tempted to look for the origin of the infection, not in the blood-vessels but in the lymphatics, it is probable that there exists a general bacillary infection, the manifestations of which are not appreciable to the naked eye, or are exceedingly scattered. This we have been able to prove on several occasions.

The Veterinary Work Done Under the Milk Clauses in Manchester and the Difficulties Met With. By J. S. Lloyd, M. R. C. V. S., Manchester. The Manchester Milk Clauses were put into force on January 11th, 1900. Between that date and April 30th, 1901, samples of mixed milk have been taken at the railway stations or *en route* to the city, corresponding to 401 farms. These samples have been tested for tubercular infection by Professor Delépine with the result that of the samples sent from 259 farms in Cheshire forty-two=16.21 per cent. were tuberculous, from 41 farms in Staffordshire, one=to 2.44 per cent. was tuberculous, from 93 farms in Derbyshire, four=4.3 per cent. was tuberculous, whilst samples from five farms in Lancashire and three farms in Salop were free from tubercular infection. From figures supplied by the farmers themselves to the Public Health Office, the estimated number of cows at these 401 farms is 8408, or an average of nearly 21 cows per farm.

The total number of farms from which tuberculous samples have been sent thus 47=11.72 per cent. At thirty-one of these forty-seven farms, 35 cows with tuberculous udders have been found. At 15 of the farms no cows having diseased udders could be found, and subsequent control samples of the mixed milk from these farms have all been reported free from infection. At the remaining one of the forty-seven farms samples of milk from suspicious cows are still in process of examination.

To give the percentage of cows having tuberculous udders among the cows represented on the 401 farms from which the mixed milk was tested, it will be necessary to strike out the fifteen farms at which no tuberculous udders could be found, and also the one farm from which the milk from suspicious cows is still under investigation. The average number of cows will then be represented by 3147 of 8408=55.45, which taking 35 cows having tuberculous udders at the thirty-one farms, gives a percentage of 0.63.

There have also been a large number of cows chemically examined irrespective of previous samples of mixed milk. In the Manchester cowsheds, 2182 were examined, and among them 8 cows were found to have tuberculous udders, equal to a percentage of 0.36. In cowsheds outside Manchester 1849 were examined, without previous mixed samples of the milk being taken, and among these 9 were found to have tuberculous udders, equal to a percentage

of 0.48. If we add up the number of cows thus, $5545 + 2182 + 1819$, we have a grand total of 9576 cows, the milk from which was tested for tuberculosis, or among which cows with tuberculous udders were found by chemical examination; and by adding up the figures $35 + 8 + 9$ we have a total of 52 such cows having tuberculous udders, which is equal to an average percentage of 0.54.

According to the Agricultural Returns for 1900, the number of common heifers in milk or in calf in England, was 1809,623. If we take 0.51 per cent. of these to have tuberculous udders we have a total for England of 10,257; or if we take the figures of Great Britain on the same basis, viz., 2,620,901 at 0.51 per cent., we have a total of 14,152 with tuberculous udders.

Against the successful working of the milk clauses certain difficulties have been found to arise. The first one is where, on following up a tuberculous mixed sample of milk to the farm, no cow is found exhibiting signs suspicious of tuberculosis.

(a) In several instances where this has been the case the farmer has admitted selling cows from his farm between the date of inspection and the date of taking the sample. But although in a few cases he has admitted that he had sold a diseased cow, or a cow which he states has not been doing well, he has only in one instance admitted selling a cow which he knew to have a diseased udder.

(b) Another possible difficulty which has been met with, is where the farmer also sells milk from his neighbor's cows mixed with the milk from his own cows. In three cases this has come under my notice. In one I failed to follow this up, but in the other two, when followed up, I failed in each instance to discover a cow with a tuberculous udder; still this is a possible source of contamination, and should not be lost sight of.

(c) Another reason given for tuberculous infection in milk is external and accidental contamination. It is possible, perhaps, that a consumptive herdsman or railway porter might infect the milk, but I think it is not probable; and a committee, appointed by the Royal Agricultural Society of England to consider the matter, did not attach any weight to this point. Another external source of contamination has been considered by Dr. Niven, and that is, contamination by dirt and dust in the cowshed. Such would be most likely to occur when the cows and cowsheds are very dirty, and when one or more of the cows are giving off tubercle bacilli in the discharges from tuberculous intestines, or in the matter coughed up from tuberculous lungs. In these cases the presence of such a cow in the herd should not escape the notice of an observant veterinary surgeon.

In all cases (nineteen) where I have been unable to find a cow with a diseased udder at my first visit to the farm, a control sample of the mixed milk was taken for a second bacteriological examination by Professor Delépine. In fifteen of these cases the milk was reported negative, whilst in four instances the milk was still found to be infected, thus proving that the source of infection was still present. In these cases I again visited the farm, and in three of them after a lengthy examination; both previous to and after having the whole herd milked I have discovered a cow showing slight signs of disease about the udder, but in neither of these cows were the symptoms at all typical of tuberculosis. In each instance, however, a sample of milk from these cows was found when examined by Professor Delépine to contain tubercular infection and to be capable of producing disease in test animals. The milk from suspicious cows on the other farm is still under investigation.

These remarks bring to notice another reason why the cow with a diseased udder may not be found on the first visit of the veterinary surgeon to the farm, namely (a) the difficulty of diagnosis.

Several authorities, including, I think, Professor Barry, have stated that a tuberculous cow can give tuberculous milk without having tuberculous disease of the udder. That is not my opinion; I can quite conceive that a cow with an udder apparently free from tuberculous disease can give tuberculous milk, but my experience with several cows is that, if the cows are kept under observation for a short time, one to three months, it will be found that the symptoms of the disease in the udder of the implicated

cow will begin to be manifest. That has been my experience in other cases besides the above three.

In one case, a sample from a "wasting" cow, with an apparently healthy udder, was reported tuberculous. Five weeks later one quarter exhibited very slight symptoms, and a sample from that quarter was found to be infective, whereas the milk from the other three quarters was free from infection. I have also met with another similar case, except that after the diseased cow was milked, slight hypertrophy of the udder could be detected.

In addition to the obscure cases mentioned, the symptoms presented during life vary considerably. Whereas many of these cows are thin and far advanced with disease, others are in good condition and apparently healthy. This is also borne out by post-mortem examination, as, out of twenty-six of these cows which have been slaughtered, nine were fit for human food, the disease being slight and localized, while seventeen were badly diseased, and were totally unfit for human food.

The second difficulty met with in working the milk clauses is the failure on the part of the farmers and cowkeepers to notify the Medical Officer of Health of the presence in their dairy of a cow affected with, or suspected of, or exhibiting signs of, tuberculosis of the udder, as required by sub-section 4.

The third difficulty is as to the disposal of cows which have been proved to have tuberculous udders. Whilst twenty-six of them have been slaughtered, the disposal of the remaining twenty-six has not been satisfactory. Eighteen have been lost sight of altogether; as some of those were in calf, it is quite probable that they may be giving diseased milk somewhere, possibly to be consumed in Manchester. The remaining eight of the twenty-six cows are in the possession of the owners, who have isolated them, and are stated to be feeding them for slaughter.

The Conditions and Diagnosis of the Soil of Tuberculosis, Therapeutic Considerations. Albert Robin, Paris. The prophylaxis of tuberculosis is not fully embodied in the private and public measures taken against the agent of the contagion.

The study of the respiratory changes permits to recognize in advance those subjects which are predisposed and enables us, consequently, to submit them to a hygiene and therapy which are capable of modifying the functional and nutritive trouble which is the necessary condition for the development of the bacillus.

The respiratory changes are increased in 92% of the confirmed and in 63% of the descendant tuberculous.

Alcoholism, the different modes of feeding, increase the respiratory changes, and are capable of producing the soil of tuberculosis in the same proportion as heredity.

The investigation of the respiratory changes permits also to determine the diagnosis of tuberculosis in doubtful cases.

The action of the different medicines and of the various medications upon the respiratory changes allows to discern those which are capable of modifying the soil and institute a new method of prophylaxis and treatment of tuberculosis.

On the Casuistic of Rare Complications of Typhoid Fever.—G. S. Kulesch (*Bolnitchnaia Gazeta Botkina*, Vol. XII, No. 19) reports a case of typhoid fever in a girl 23 years old. The patient died on the 19th day of admission as a result of a double catarrhal pneumonia complicating the disease. On autopsy the usual lesions of typhoid fever were found and also a severe membranous gastritis. The gastric mucosa was covered with a fibrinous exudate, and showed on microscopic examination coagulation necrosis, infiltration of lymphoid cells, thrombosis of the blood vessels, and phlebitis. Having reviewed the conditions found in this case, as well as the data obtained from literature, the author comes to the following conclusions: 1. The mucous membrane of the stomach is subject, in the course of typhoid fever, to changes analogous to those occurring in the intestine. 2. Thrombo-phlebitis observed in typhoid fever may take place also in the veins of the stomach. 3. Non-specific membranous affections of the stomach, like those in the intestine, develop on a soil weakened by preceding morbid changes in the tissues. [A. R.]

SWEAT BATHS AND BATHS WHICH INCREASE
BODILY TEMPERATURE.

By DR. R. FRIEDLAENDER,

of Wiesbaden, Germany.

Written specially for the PHILADELPHIA MEDICAL JOURNAL.

Translated with permission of the Author by Max R. Dinkelspiel.

In former publications* I have repeatedly alluded to the distinction which must be made between the physiological and therapeutic action of those hot baths which principally cause an increase of sweating without essentially changing the bodily temperature, and such, which in addition to causing diaphoresis also raise the bodily temperature.

We know that in local treatment by heat, as is carried out by means of hot applications or hot air, (Tallermann's apparatus, electrotherm, etc), a material increase in the bodily temperature does not occur, even if a considerable degree of heat is employed. This is the case in local as well as in general thermic procedures such as Priessnitz's applications and packs, dry packs, etc. But in a general conveyance of heat to the body an increase in bodily temperature can take place. In the so-called indifferent baths, with a temperature of from 34-35°C. the loss of heat, and the heat production, are normal in the healthy individual. If, however, the temperature of the bath is increased, the organism tries to maintain its own temperature by increased heat elimination through the skin. This is in the first place made possible by the hyperemia of the skin and the subcutaneous tissues, resulting from the vascular dilatation due to the irritation from the heat. The skin thus becomes warmer itself, and its heat conductivity, as well as that of the subcutaneous adipose tissue, becomes increased. Secondly, an increase in heat elimination occurs from the increased diaphoresis (which is soon set up in the bath by the heat irritation), and the continual evaporation of the sweat from the skin. Third, an increase in heat elimination takes place by reason of the increased amount of heat and evaporated water which escape during exhalation. If these three processes, among which the evaporation of the sweat from the skin plays the most important role, are not able to establish the "physical regulation" described by Matthes and others, an increase in temperature will take place to such an extent, as to give rise to artificial fever, to hyperthermia. There does not exist any chemical means by which the increased conveyance of heat to the body can be regulated in the sense of a retardation and decrease of metabolism.

But in that class of thermic procedures, of which the moist pack (Priessnitz) is the chief type, and in which there is not an increased heat supply from without, but only a decreased elimination, as a result of covering the skin, the "physical regula-

tion" previously alluded to, is enabled to prevent an increase in bodily temperature. Where there is a general conveyance of heat to the body the physical regulation in most cases is enabled to check the rise of bodily temperature, provided the most essential factor of the regulating phenomenon, the increase in heat elimination, caused by evaporation of the sweat from the skin, takes place unimpeded. Such is the case where there is a general heat supply in dry media, in dry hot air baths, Roman, Turkish and electric light baths, as well as in hot sand baths.** In such baths the diaphoresis is profuse, but the increase of bodily temperature in spite of the increased heat supply, remains unimportant.

If, on the other hand, the evaporation of sweat is impeded in hot and moist baths, like the Russian steam bath, an increase in bodily temperature easily occurs, and varies according to the intensity and duration of the heat influence. This artificial rise in temperature is accompanied by an increase in metabolism, both in a quantitative and qualitative sense. The decomposition of albumin also rises above the normal. The investigations of Pflüger, Bartels, Naunyn, Schleich, Formanek and Topp, show that the production of urea is increased by hot baths. H. Winternitz not only observed as a result of hot water baths an increased decomposition of substances free from nitrogen, but an actual increase of oxygen consumption and carbon dioxide elimination to an extent never observed even in high fever.

In order to investigate the difference in the action of hot baths in dry and moist media, I have conducted a series of experiments upon myself in conjunction with a colleague (Dr. Boettcher), which I will briefly report.

It was found that at a similar temperature and duration of the baths the bodily temperature rises much higher in a moist medium, like the steam bath, than in the dry hot air of the electric light bath. From the results obtained in the experiments with five steam chest baths, and five electric baths, tabulated in the following compilation, it will be seen that with an average temperature in the steam chest of 50°C. there occurred in several experiments an increase in temperature (the temperature was always taken by the mouth) of 1.5°C. On the other hand, in the case of the electric light bath, in spite of an average temperature of about 60°C., and notwithstanding that the duration of the baths in two experiments was increased, the bodily temperature showed an average increase of only 0.5°C. Therefore, estimating the temperature of both baths at 50°C. there was an increase in bodily heat of 1.5°C. for the steam bath, and 0.4°C. for the electric bath. The influence upon the pulse also varies in these two varieties of baths; the steam chest bath caused a much higher increase in the frequency of the pulse than the electric light bath.

*Transactions of the Internal Congresses, 1897. Transactions of the International Congresses, 1897. Chapter on "Thermotherapy" in the "Handbuch der physikal. Therapie" of Goldscheider and Jacob, Leipzig, 1901.

**The "sweat bath in bed" occupies an intermediate position between the two varieties of baths above discussed. It is originally a bath in hot dry air, but on account of the small volume of air, and because no renewal of the air takes place, there must soon occur an increase in moisture.

While the frequency of the pulse in the steam bath attained an average increase of 63(!) beats to the minute, that is, an actual increase from 80 to 143 beats, the increase in the case of the electric light baths, averaged only 38 beats, or an actual increase from 80 to 118 beats. Together with the increased pulse frequency, there was an increase in vascular relaxation, (radial and carotid arteries) which was more marked in the steam bath than in the electric light bath.

After completion of the baths the frequency of the pulse and the temperature diminished quite rapidly, so that after 15 to 30 minutes normal conditions again were reached; this recession occurred much more quickly when a cool rubbing was performed immediately after the hot bath. Subjective symptoms of palpitation of the heart, heat oppression, and congestion in the head, were much more prominent in the steam bath than in the electric light bath, in which they were almost entirely absent, and even in the steam bath were only noticed to a slight degree when there was a high temperature and longer duration of the bath.

The frequency of respiration was not essentially changed in either form of bath, but there did occur an increase in the depth of the breathing, which also showed itself much more prominently in the steam bath than in the electric light bath. In the

latter the diaphoresis was subjectively more marked than in the steam bath. In contradistinction to this, however, is the fact that a larger decrease in bodily weight could not be demonstrated in the case of the electric light bath. The average loss in weight (about one pound per bath), if anything, was less, after the electric light bath. After the experiments the loss in bodily weight was compared by both experimenters, experimenter A, having even found an increase in bodily weight.

This shows, as I have previously emphasized, that a marked reduction of bodily weight can only be accomplished by diaphoretic procedures when the increased loss of water is not again replaced, and furthermore that a treatment of obesity by means of dietetic regime, and, above all, physical exercises, is to be eminently preferred to the hot bath treatment.

If we again briefly summarize the results of these experiments, it is above all remarkable that the hot bath in the moist medium causes a much greater hyperthermia, and a much greater accompanying increase in pulse frequency, than the bath in dry hot air. This is of the highest importance, in considering the indications and contraindications for these baths.

Common to both varieties of baths are certain

actions of the heat upon the circulation, sweat secretion and nervous system. The blood vessels of the skin and the subadjacent tissues become dilated, and a peripheral hyperemia results, and with a simultaneous decrease in blood pressure, and increase of the vascular dilatation the frequency of the pulse becomes increased; the latter phenomena are certainly much more pronounced in the case of the hot bath in moist media.

Furthermore, in both varieties of baths there is marked sweating, although in the dry media the diaphoresis appears more pronounced (in the hot sand bath a loss of bodily weight up to 3 Kg. was observed). The increase in sweat secretion, where there is insufficient supply of fluid, may give rise to an impoverishment of water in the body; at any rate by the replacement of the lost fluid with fluids from the tissues, a stimulation is produced which is of great importance for the removal of transudates and exudates. The constituency of the sweat in salts and organic material is only slight, but the sweat, like the urine, possesses toxic properties. On account of this toxicity it has been repeatedly attempted to explain the therapeutic action of sweat baths by assuming that the pathological toxins are eliminated by the sweat; this, however, is not supported by experimental proof, it having not yet been shown that the sweat possesses a greater toxicity in the sick individual than in the healthy one. Various poisons, like mercury, arsenic, and potassium iodide, are eliminated by the sweat. In the treatment of nephritis with sweat baths, it is of importance to consider, as pointed out by Koehler, that in renal diseases albumin is eliminated by the sweat. The influence upon the nervous system of the analgesic and relaxing effect of the heat may also be considered identical in both varieties of baths. On the other hand, as we have seen, the influence of the hot baths in moist media, surpasses in a most important feature that of the dry hot baths, on account of the increased hyperthermia, and the accompanying intense stimulation and acceleration of metabolism.*

The question then arises as to the indication and justification for the employment of artificial fever as a therapeutic procedure. The beneficial results which have been obtained in the treatment of many diseases in Japan, where, according to the reports of Baeltz, it has become the custom to bathe in very hot water, and furthermore, the popularity of the steam baths, which has existed since ancient times among the Russians, for the prevention and cure of the greatest variety of pathological conditions, all seem to prove that the artificially produced temperature rise possesses a particular therapeutic value. If we start out with the assumption that fever chiefly represents a natural process which serves the purpose of immunizing and eliminating pathological materials, like bacterial products, etc., it can readily be assumed that in certain cases the production and intensification of this reaction will be of use. In which cases, and how far, such a hyperthermic ther-

apy is justified and indicated, can only be ascertained by careful clinical examination, and extensive bedside experience. As an encouragement for further experimentation in this direction, are the investigations conducted by Walter, Rovighi and Filehne, which showed that, if infected animals were subjected to a general intense heat treatment, they were better able to withstand infection than similarly infected animals not subjected to this treatment.

Furthermore, of importance for this subject is the hyperleukocytosis which can be regularly observed in temperature increasing baths. After intense heat influences in moist media, like hot baths, steam baths, etc., I could regularly show an increase of the leukocytes up to 25%. As the red blood corpuscles during these experiments were increased to a much less degree, and in some cases even decreased, the conclusion was justified, that the condition of the leukocytes was not only dependent upon vasomotor phenomena, but that a specific attraction for the leukocytes was set up by the intense thermic irritation. We must therefore, consider the manifestations recognized under the name of chemotaxis side by side with thermotaxis, notwithstanding that the hyperleukocytosis caused by thermic irritation is much less than that caused after the administration of certain chemical substances. In a large number of experiments in this direction I have always found that the degree of leukocytosis after the influence of heat, is dependent upon the increase of bodily temperature, and therefore in inverse ratio to the quantity of evaporated sweat. In the hot air baths but a slight increase of leukocytes was observed, while in the hot water bath, and in the steam bath, the number of leukocytes was markedly greater. Regarding chemotaxis, I frequently found that immediately after the heat influence there was a decrease in the leukocytes, which was only later followed by the hyperleukocytosis. Regarding the degree of leukocytosis caused by the heat I found individual variations, which appeared to me to be dependent upon the general constitution. In certain vigorous individuals the increase in leukocytes was more marked than in weak anemic subjects.

In order to decide the question whether we had to deal in these cases with entirely transitory phenomena, I have repeatedly examined the blood many hours after the hydrotherapeutic procedure, and in many cases found that even 24 hours after the influence of the thermic irritation an increase in the number of leukocytes existed. For example, in a series of experiments performed by employing steam baths once daily for twenty minutes, the number of leukocytes per cm. increased within three days from 6500 to 9500; I observed an increase of 1000 leukocytes to the cm. on each one of these three days, showing that the increase of one day persisted until the next.

This mobilization of the leukocytes, which occurred under the influence of baths that increased bodily temperature, is deserving of particular attention when we take into consideration how great a role the leukocytes play in the battle of the organism with disease.

Not only are various opinions produced regarding the indication for each variety of bath, but also vari-

*Just as I was about to send this article to press I received a communication containing a report of experiments performed by Dr. Salomon under the direction of Prof. v. Noorden, entitled, "Concerning the Action of Hot Baths and Electric Light Baths." The results concur so far with mine in that the author showed "that the increase in oxygen in the hot air and electric light baths did not differ markedly from the observations of Winternitz in the case of the 'hot bath'."

ous views are entertained regarding the contraindications for such procedures. The hot bath in a moist medium makes more exacting demands from the organism than the simple sweat bath. The artificial fever affects the heart by far more intensely, as has been already observed in the increased pulse frequency. As soon as an increase in bodily temperature occurs the intensification of the processes of metabolism, as it were, affects the economy to a much higher degree than in the case of a simple sweat bath. We must, therefore, be particularly careful in employing baths that increase bodily temperature in patients with cardiac and vascular affections, simple sweat baths being much better tolerated by such individuals. A well pronounced cardiac insufficiency, or arteriosclerosis, is a decided contraindication to the employment of baths that increase the temperature of the body. Also, in older persons, as well as in anemic and cachectic individuals, we must be very reserved in ordering such baths; furthermore, in individuals with apparently healthy circulatory apparatuses, in whom increased functional cardiac activity frequently occasions increased dilatation of the peripheral vessels, such baths are contraindicated.

The effect of the temperature increasing baths is, to a certain extent, weakened when the head of the patient remains in cool air, as, for instance, in the case of the steam chest bath. In such cases where hot baths on account of their general influence are contraindicated, local treatment by means of heat is frequently utilized, in the shape of hot air apparatuses, thermophores, douches, etc. This applies especially to a series of affections of the joints, muscles and nerves.

In conclusion, in order to briefly emphasize the indications for each variety of bath, we prefer temperature increasing baths:

(1). In combating infectious and toxic conditions. In acute and subacute diseases due to exposure, catarrh of the upper respiratory passages, fresh rheumatic affections of the muscles and joints, and also in other infections, the onset of which is not characterized by high fever, and in which individual conditions render an increase of the fever permissible and desirable for the course of the pathological process. Furthermore in syphilis, and in a general gonorrheal infection.

(2) When an intense increase of metabolism is indicated from other causes, such as autointoxication, and in conditions affecting metabolism, like gout.

On the other hand, we favor sweat baths:

(1). When a cure by means of free diaphoresis is contemplated; in exudations and transudations, in nephritis with edema, in hydremia and chlorosis, in metallic poisoning, and in obesity as an adjunct to other methods of treatment.

(2) When chronic inflammatory processes are to be influenced by peripheral hyperemia. In chronic and especially rheumatic affections of the muscles, joints and nerves, in the residual conditions of acute articular rheumatism, in chronic muscular rheumatism and arthritis deformans, in neuritides, and in tubercular arthritic affections.

TRAUMATIC HYSTERIA: CRANIAL OPERATION AN INTERESTING PATHOLOGICAL CONDITION; RECOVERY.

By FRANK R. FRY, A. M., M. D.,

of St. Louis, Mo.

Professor of Diseases of the Nervous System, Medical Department Washington University, St. Louis, Mo.

I first examined Miss N. A., August 19, 1899. Four years previously, almost to the month, while romping with some girl friends, her forehead came violently in contact with another girl's head. She was unconscious for about two hours after the blow and in a more or less dazed state for a still longer period. About three months after the accident serious convulsions began to appear. During a period of four years, between the accident and the operation described below, there was a marked departure from her usual condition of health, a contrast which I shall attempt to make evident in the following notes.

Prior to the accident she had always been well. She had never had a serious or tedious illness, nor a convulsion of any kind. Her schooling had not been interrupted by illness. She was fond of and fully capacitated for household work and for such recreations as dancing, horseback riding and walking. Following the accident there developed within a few weeks convulsions of a very distressing kind, a constant headache, and an increasing physical and mental lassitude.

At my request, Dr. W. R. Ferrell, the attending physician, kindly furnished the following brief resume of the case:

"Miss N. A. suffered continually with a headache from a few weeks after the injury until the operation. The convulsions came suddenly and sometimes lasted for hours with practically no intermission. The first one that she ever had came suddenly while she was at dinner, with no warning of any kind. It lasted six hours, when she seemed to come under the influence of the drugs administered. During this and all subsequent attacks which I saw, the cramping would seize all portions of the body, then she would writhe all over, pull her hair and cry aloud and at times she would seem to smother as though almost asphyxiated. The attacks came in groups about every four weeks. They would disappear in about three days if kept well under the influence of medicine. It was noticed that before the attacks she complained of weakness or prostration and was somewhat depressed in spirits. The operation was followed by a remarkable change. Her appearance since has been that of perfect health, no headache, no pain anywhere, no sign of a convulsion, spirits the best. A few months ago she married. Her father informed me recently that she had been having some slight attacks of vertigo with nausea which they attributed to a natural cause."

From the patient and her father I obtained a clinical history that coincided substantially with Dr. Ferrell's, and nothing important in the way of family history beyond the one item that the mother had had migraine attacks. They quite agreed that the convulsions were becoming more frequent and prolonged, the headaches more severe, and that the disinclination or incapacity for mental and physical occupation and activity was increasing; evidently an increasing neurasthenia which had deepened several shades in the past few months.

The patient was under observation at St. Luke's Hospital nine days; and systematic examinations were made, the details of which I shall not recount, but give only the more important results: A well-

developed woman, 20 years old (at the time of the accident she was 16 years old); blonde type; a florid complexion, giving the impression of habitual vasomotor dilatation; of good proportions and free from any important degenerative signs. There was no evidence of visceral or organic disease of any region of the body, nor were there signs of any focal disease of the nervous system.

We witnessed a number of the convulsions and remarked the several stages and various details of a well-developed hysterical seizure of the *grand type*: A premonitory stage of discomfort and disquiet; with her it seemed to be a malaise which started in the precordial region and radiated with accumulating force and severity to all portions of the body. As this increased it was followed in a typical way by the period of mental anguish, fright and delirium; and then the epileptoid spasm, consisting of tonic seizures followed by writhing, clutching, gyrations of the extremities, and contortions. Especially we noticed the frequency with which she ducked her head down and bored it into the pillows, in a manner often seen in these attacks. Finally the convulsive condition gave way with now and then a ripple of it through the extremities as the sensorium gradually cleared and consciousness returned to find her in a condition of lassitude and inclined to sleep.

There was no scar or sign of injury to the skin. The region of trauma on the forehead was hyperesthetic; not excessively so, but on all occasions manipulation and slight pressure were uncomfortable to the patient. By pressure upon it, in a deliberate manner, I induced a convulsion of the kind above described. In order to accomplish this, however, considerable pressure or force was necessary; therefore, having selected for the first trial an opportune time and having fully satisfied myself that the site of trauma was an hysterogenic point, I did not repeat the experiment for reasons which are readily understood.

During the periods when she was free from seizures, there was no history of the appearance of any of the so-called interparoxysmal symptoms of hysteria. Nor did we find these during our examination, although we carefully looked for psychical, sensory and motor phenomena of this kind. Even the pharynx was not anesthetic, the visual field was not contracted, and nowhere could we find anesthetic, hyperesthetic, or hysterogenic areas, save the one region of the trauma as above described.

Next to the convulsions the headache demanded attention. She insisted that she was never free from it. She described the pain as radiating from the site of trauma in all directions and to all portions of the head, varying in severity, but always present; sometimes a dull, heavy, aching; sometimes sharp, shooting pains. Occasionally there came a pain paroxysm of great severity, lasting for hours, accompanied with nausea and a boring pain in the orbit on the side of trauma—in short, all the features of an attack of ophthalmic migraine. In some of these attacks she became quite blind in this left eye. It was, however, the transient blindness of migraine rather than the more persisting hysterical kind.

There was no mental weakness, no psychical symptoms aside from the attacks. The nurses who

were with her daily in the hospital gave her the best of reputations for amiability and intelligence, and she impressed all of us in the same way. There was a condition of physical and mental listlessness, as it were, growing out of the enforced idleness of her long illness and a fading hope of ever recovering from her unfortunate plight. When alluding to this latter possibility, she sometimes became emotional, but not hysterically or unreasonably so. She was ready to undertake anything in the way of treatment that the physicians agreed upon.

She entered St. Luke's Hospital August 19, 1899. On August 28th Dr. Harvey G. Mudd operated. He has kindly furnished me the following brief description of the operation:

As nearly as could be determined the central point of the trauma was on the line of the coronal suture and three inches from the sagittal on the left side. This point was accordingly made the center of a circular skin flap with pedicle below. The portion of bone to be raised was outlined with a small chisel, grooved with a V-shape, and the line cut through with a plain chisel and mallet. A portion of the bone in the lower segment, corresponding to the skin pedicle, was broken back, as the osteoplastic flap was lifted and turned downwards. The portion of bone raised measured two and one half (2 1/2) inches in each diameter. The presenting dura seemed normal. It was incised around the circumference of the opening and turned down with an attaching pedicle much as the skin flap. The exposed arachnoid showed plainly inflammatory thickening. On introducing the finger under the edge of the bone it was found that the dura was attached to the pia-arachnoid in all directions for a considerable distance about the site of the opening. These adhesions were carefully broken up, producing free hemorrhage which, however, stopped very shortly. The flap of dura was stitched into place with cat gut. The bone flap fitted into place without difficulty. The scalp was sewed and the wound closed without drainage. Union by first intention took place throughout. The dressing was removed in about two weeks. Within two hours after the operation the temperature was 104.8° and pulse 128. This soon subsided and afterwards remained normal, or nearly so.

The pathological findings in this case emphasize the necessity of making reasonably large openings when intracranial inspection is undertaken. The adhesions between the dura and pia-arachnoid were just beyond the exposed area and were only discovered when the finger was introduced to explore. If the site selected had been trephined with the largest size crown and the dura opened, I am sure the slight exudation in the arachnoid just at this point would not have tempted a thoughtful surgeon to enlarge the bone opening, in this region especially, for he would have to think of the unsightly depression he would thus make in the forehead of a young lady patient. The result of the osteoplastic flap was a fine linear scar and no depression or unevenness whatever.

The only possibility of a sufficient exploration is through a large opening. The surgeon knows nothing when he has peeped through a trephine hole.

The presence of the adhesions I would explain as follows: at the site of trauma there was produced a local edema of the membranes, and this edematous area was circumscribed in all directions by a slight exudation and the adhesions found were the remains of this inflammatory circle.

After reporting an interesting case of traumatic (?) hysteria, a recent writer* puts the query: "Was

*Dr. C. B. Burr, Flint, Mich., Reflections on Traumatic Hysteria. Proceedings American Medico-Psychological Association, 1900.

the case scientifically operable?" The question arises in the same form here: In the absence of focal motor and sensory signs were there other considerations weighty enough to scientifically determine an intracranial exploration? In my case the evidence may be stated as follows: A site of trauma definitely located, with indications that it was severe in character; immediately following the trauma prolonged loss of consciousness (about two hours); a constant headache of severe type, focused, as it were, at the point of trauma and dating distinctly from it; grave hysterical seizures, recurring frequently during a period of four years and accompanied with much mental and physical lassitude, which also date definitely from the trauma.

As already stated, the attacks were the only pronounced or characteristic hysterical phenomena present, but their presence admonishes us to carefully weigh all other matters. For instance, in the light of the hysterical spells the prolonged unconsciousness may also have been hysterical, probably was; and why may we not say the same about the headache? With this suspicion once aroused, we may not accept any of the symptoms that were present as reliable guides to the amount of injury to bone, membrane or brain. Even under circumstances where no such suspicion exists we often cannot determine much about the brain trauma from the skull trauma. The cranial injury is one problem, the brain injury another, and the functional disturbance still another, and this latter may only be made out by a careful study of symptoms. In the presence of hysterical symptoms the problem, to say the least, becomes perplexing, often unfathomable. A multitude of hysterical phenomena may spring from apparently trifling disturbances as well as from severe physical trauma, and that, too, in individuals who previously have shown no history or sign of this kind. Evidence is not lacking in proof of this statement but by way of impressing it as I would wish to in this connection, it may not seem amiss to quote the language of a prominent authority:* "All forms of shock, whatever may be their nature or intensity, may excite hysteria, and the disturbances caused by earthquake or by lightning do not necessarily determine graver accidents than a simple confusion received under the most ordinary circumstances." * * * "There are, indeed, certain kinds of shock which may provoke hysterical symptoms in individuals who have no trace of predisposition to the affection."

In view of these difficulties, how are we to consider cases like the one here reported, and that of Dr. Burr's? Briefly, the situation in his case was as follows: A young woman (age not stated). Two years previously an alleged injury to the cranium (site not mentioned) from a chair in the hands of her mother. No evidence of injury to scalp or skull, no cicatrix, no increased tenderness. She frequently had typical hysterical attacks; at times was dull and confused, and on some occasions almost stuporous; showed insane changes of temperament, and even well marked dual mental states, the phases of which extended over months. She at times complained of severe headache referred to the region of alleged trauma and often of sharp pains in this

locality. There was no paralysis or objective sensory symptoms or other focal symptoms of any kind. A sister (whom Dr. Burr had observed) had been in very much the same condition, and there were other items, especially in her mother's case to show a neuropathic family tendency.

During two months of sanitarium treatment under Dr. Burr's observation, she improved. Soon after leaving the hospital she developed profound hysteria. A surgeon diagnosed *meningeal* or *cerebral irritation* at the point of trauma. A button of bone was removed with a Galt trephine. It was affirmed that there was a pathological adhesion of the dura to the bone at the site of the opening and for some distance in all directions. The dura was incised and seemed thick and vascular. Beyond this nothing pathological is mentioned. The patient was so promptly and so much improved that she and her friends believed there was a complete restoration of mental and physical health from the operation.

These two cases are quite similar. They belong to a certain class or type, which fact the neurologist recognizes perhaps more fully than other practitioners; a class of cases in which after some cranial injury there is a question whether there has been a cerebral injury, and in which there is no satisfactory way of deciding on account of the presence of hysterical phenomena, or of certain other vague psychical symptoms which do not enlighten the observer who best understands them, but, on the contrary, only mystify a diagnosis. Even after we have operated and discovered a lesion we may not positively affirm its relation to any of this class of symptoms, no matter what its magnitude. The excision of a sensitive scar from the scalp or a hole trephined in the skull, has been sufficient to dispel on many occasions an elaborate symptomatology of this kind. It is unfortunate that more of these cases with descriptions of the surgical interference undertaken for their relief have not been carefully recorded. Many instructive instances have never reached a record, as every experienced neurological practitioner, and many others, can testify. In looking over reported cases one is impressed with the facts of insufficient clinical histories and very imperfect surgical operations. Yet when carefully analysed the volume of this evidence would sustain our conclusions, hereinafter expressed.

Dr. Burr concludes his communication as follows: "Not one symptom suggested surgical interference. We were chagrined that the value of the operation should not have been foreseen. It was, apparently, necessary, and brought about the patient's recovery, but I fear that under similar circumstances we should act as before. The case is reported to show the possibilities of surgical relief in cases of traumatic hysteria, and it occurs to me to ask two questions in connection therewith:

Given the facts as related, could a neurologist recommend operation?

In a similar case would an operation of such magnitude be justifiable with the possibility of pathological findings and in the absence of them for its suggestive influence?

Or, in other words, could we assume the existence of disease, or failing to find it justify surgical measures because of the presumable moral effect? Or, put more briefly still, was the case scientifically operable?"

I have already shown why my case was not *scientifically* operable; for notwithstanding we knew the site of trauma, that it was tender and hysterogenic and a constant pain center, we actually had no more

*Pere. Twent Cent. Proc. Med., Vol. 1

practical or positive data to proceed from, than were present in Dr. Burr's case. We simply operated to give the patient the benefit of the doubt. The two cases here cited, as well as many others, show the advantage of doing this. I believe it useless to try to formulate any rules, except, (1) if in any case there is doubt about the traumatic origin of hysterical or other psychical symptom, or about the possibility of surgical relief, the patient should have the benefit of this doubt; (2) to determine these matters the case should be *thoroughly* canvassed from a neurological standpoint.

THE USE OF DRUGS IN PULMONARY TUBERCULOSIS*

By W. R. HUGGARD, M. A., M. D., F. R. C. P.,

of Davos Platz, Switzerland.

In regard to the use of drugs in pulmonary tuberculosis there is much difference of opinion amongst medical men. By some physicians drugs are considered either useless or harmful; by others one drug or method of treatment is considered *the* treatment. Creosote, cinamate of soda, arsenic, formaldehyd, and various other drugs have each their devoted adherents, who regard their pet remedy almost as a specific. A large number of medical men, while not discarding drugs altogether, employ them only for the relief of urgent symptoms.

All these views are in my opinion too narrow; some over-estimating their limitations. From another standpoint also the foregoing views are too narrow. The great variety in the clinical forms of phthisis is dropped out of sight; and the same line of treatment in regard to remedies is sometimes adopted without sufficiently precise reference to the case in hand.

The object of this paper is to point out some of the advantages that may be gained by the judicious use, and some of the evils that arise from the injudicious or indiscriminate employment of drugs in pulmonary tuberculosis. The broad principles will also be indicated which determine my own selection of remedies according to the variety of the case. The subject is one in which the comparison of individual experience is of the greatest value in extending our knowledge, and in putting it on a firmer basis.

The first point to be made clear is that up to the present no specific has been found for tuberculosis. Not merely so; but there is no drug that is useful in all cases. Nevertheless, there are various drugs that favorably influence the course of some varieties of the disease always provided that they are well tolerated by the patient, and that they do not cause any disturbance of appetite, digestion or assimilation.

Time does not permit even a hasty review of all the drugs useful in phthisis. The various conditions only that indicate or contraindicate one remedy rather than another will be rapidly considered.

What medicines have we at our disposal? Drugs may favorably influence the course of the disease—

1. By improving the general health; as for example, arsenic, quinine, strychnine, lime, phosphorus preparations.

2. By increasing the local resistance of the affected tissues, as creosote and its derivatives, salicyl preparations, and counter irritants.
3. By modifying the quantity or character of the secretions, as the balsams, the terebinthines, the essential oils, morphine and apomorphine, and inhalations, especially of formaldehyd.
4. By controlling symptoms that react prejudicially on the patient. Amongst these are:
 - a. Digestive ailments.
 - b. Excessive or needless cough, which shakes and exhausts the patient, causes fever, or prevents sleep.
 - c. Scanty expectoration and retention of secretions.
 - d. Fever, which spoils appetite, and prostrates the patient.
5. By removing complications, such as syphilis.

In the choice of remedies the points to be considered are not the same as guide us in diagnosis or in prognosis. The first and most important point to recognize is, that treatment by medicines must be altogether subordinate to general hygienic management—good food and fresh air with rest and exercise according to the individual needs of the patient.

The first and most important point in treatment is to consider the state of the digestive system. If the stomach or digestion is out of order drug treatment is, as a rule, inadvisable, except in so far as it may aid in restoring the digestive function to a normal state, or in removing some condition that tends to prolong the digestive ailment. For example, appetite and digestion not uncommonly improve with the artificial reduction of temperature, or with the control of excessive cough. In such cases we must feel our way cautiously and be guided tentatively by the results.

The most important indication then is to get the stomach and bowels into proper working order. Nothing goes right so long as the digestion is wrong.

Temperature is the next most important guide to treatment. Pyrexia will in a large proportion of cases yield to absolute rest, bodily and mental, combined with life in the fresh air. In many cases, however, a return to a normal level of temperature can be hastened by the administration of small doses of phenacetin—one to three grains—in combination with quinine and salol and sometimes arsenic. Taken in this way phenacetin seems to have rather a tonic than a prejudicial effect on the heart and on the general health, and many without hesitation be continued for months if need be. My experience of other antipyretics, save for quite occasional use, has not been so favorable, with the exception perhaps of salipyrin.

Arsenic, strychnine, quinine, and salicyl preparations greatly diminish, in my opinion, the tendency to recurrent attacks of subacute inflammatory character and those recurrent febrile attacks without any change in the physical signs which are so marked a feature in a large number of patients suffering from pulmonary tuberculosis. These recurrent febrile attacks are no doubt of very various origin, tubercle as a rule rendering the organism highly sensitive to influences that cause pyrexia. The drugs I have mentioned seem to me to diminish this

* From advance sheets furnished by our representative at the Congress on Tuberculosis, London.

sensitiveness to febrile reaction. In doing so they accomplish something more than the avoidance of a temporary drawback or inconvenience. In tuberculosis, more than in any other disease, slight drawbacks are apt to provoke further prejudicial effects, and each morbid condition tends to become chronic. In averting slight drawbacks, therefore, we avoid great dangers which might completely alter the course of the disease. The disease is one in which preeminently anything short of the best is bad.

Next to pyrexia as a guide to treatment, I would place a marked tendency to hemoptysis. Creosote and guaiacol increase, in my opinion, the liability to pulmonary hemorrhage—as well, in fact, as to pulmonary inflammation—and should be avoided where such a disposition is present. The lime salts, the terebinthates, and the balsams have, I believe, on the contrary, a somewhat restraining influence, as has also morphine in minute doses.

The treatment of excessive cough requires much judgment. A closely allied object of treatment is the modification and, as a rule, the diminution of bronchial and pulmonary secretion—the “drying up of the lungs.” A certain amount of cough is in a large number of cases indispensable, and has a salutary influence. The problem is to secure the removal of the pulmonary and bronchial secretions with the least amount of violence, exertion, or fatigue for the patient. Sometimes the secretions are extremely abundant, sometimes too scanty. The balsams and the terebinthates and tar for the most part diminish bronchial secretion, and the terebinthates commonly render it at the same time less tenacious and easier to get up. Minute doses of morphine—from one hundred and twentieth to one sixtieth of a grain of any of its salts—diminish secretion, but as a rule render it more tenacious. Apomorphine in small doses—one-twentieth to one-sixteenth of a grain of the hydrochlorate—loosens the secretion without making it much more abundant. The recently-introduced morphine derivatives, heroin and dionin, greatly diminish expectoration, while they are free from the drawbacks that morphine has, of rendering the secretion viscous and difficult to get up. They are also practically devoid of constipating effect, and they do not upset the digestion. For the last two or three years they have almost altogether replaced in my practice the phosphate of codeine, which has fewer drawbacks than has morphine for the relief of excessive cough.

The most valuable agent that I am as yet acquainted with for modifying the bronchial and pulmonary secretions is the vapor of formaldehyd. For the last three years I have used this drug extensively, and with more and more satisfactory results. When steadily used it generally causes the secretions to be less purulent and more mucous, at the same time diminishing the amount and rendering expectoration easier. Where the use of the drug has been steadily persisted in for months tubercle bacilli have, as a rule, also become less numerous, and in some old cases even have disappeared. The mode of employment requires a little care. The best way, in my opinion, to use formaldehyd is by means of a muzzle inhaler. The strength of the solution should at first not be more than two or three per cent. in rectified spirits of the ordinary forty per

cent. solution. The addition of some essential oils renders the inhalation quite agreeable. Only from five to ten minims at first should be put in the inhaler, and this quantity should be renewed every fifteen or twenty minutes, the entire time of inhalation being from two to four hours a day. The strength may be gradually increased up to six or eight per cent., and sometimes even to double that amount. If cough is very irritable, chloroform may be added to the inhalation. From independent observations I am strongly of opinion that chloroform, apart from its soothing influence on the cough, has in some cases a beneficial influence on the disease. It must, however, be used with judgment. I have known it seemingly give rise to pyrexia, by causing retention of secretion. The inhalation of formaldehyd, on the contrary, tends to considerably diminish pyrexia due to the absorption of toxins. Formaldehyd has another advantage. If not too strong, it diminishes irritability in the pharynx and larynx. It is, however, very irritating to the eyes and nose, and for this reason should be used only with an oral inhaler, or, if the Burney Yeo oro-nasal inhaler is employed, it should be placed below the nose.

According to my experience syphilis is a complication of pulmonary tuberculosis in a much larger proportion of cases than is usually thought. In such cases I consider the treatment of syphilis to be of the first importance. Small doses of the perchloride of mercury have then, instead of a depressing, a remarkably tonic influence. Intra-muscular injections of mercurial salts, though more strikingly beneficial, have, as a rule, the drawback of being excessively painful. To this rule, however, *huile grise* or mercurial ointment, rubbed up with sterilized oil, is an exception. The iodide of ethyl by inhalation is perhaps the least objectionable, while not the least efficacious mode of giving iodine. It may be combined with the formaldehyd inhalation.

To sum up then, my line of treatment is determined, in the first instance, by the digestive system, by the general health, and by the state of nutrition.

If digestion is bad, the only drugs indicated are such as will restore it to a normal condition. If digestion is good, the general condition satisfactory, and the patient improving, I refrain from using drugs unless some definite indication is present. Amongst the most important indications for drugs are persistent afternoon pyrexia in spite of absolute rest out of doors; a tendency to recurrent febrile attacks or to slight inflammatory attacks. This tendency is usually combined with impaired nutrition and with a low state of general health. In these conditions arsenic, strychnine, quinine, and salol are amongst the most useful tonics. Active softening, excessive cough, over-abundant expectoration, and, more rarely, scanty expectoration, expectoration of extremely purulent or nummular character, require attention; and the drugs useful for these conditions generally seem to me to have a favorable influence on the course of the disease in addition to the temporary relief from discomfort they may afford.

Amongst such drugs are formaldehyd vapor, creosote and its derivatives, except the carbonate of guaiacol, which has generally seemed to me to be inert, terpin hydrate, oil of cinnamon, myrtol, the balsams, and the lime salts. In sluggish chronic

softening, counter-irritation by iodine or by small tlying blisters is of the greatest use. When an old syphilitic taint is present its removal should be our first care.

The short time at my disposal does not permit a detailed examination of the points I have brought forward, and my remarks are rather to be considered in the light of heads for discussion than as even a partial exposition of the subject. What I have said may, however, I trust, be sufficient to induce others to bring forward their experience on the same lines.

THE INHALATION OF FORMIC ALDEHYDE AS AN AID IN THE OPEN-AIR TREATMENT OF PULMONARY TUBERCULOSIS.*

By DR. CROWRY MUTHU, ¹

Physician to Inglewood Sanatorium, St. Lawrence, I. W.

Formic Aldehyde.—The discovery of micro-organisms as the exciting cause of disease has brought into prominence many antiseptics and disinfectants, the object of which is to check their growth or destroy them. One of the latest of these is formic aldehyde which is obtained by the oxidation of methyl alcohol.

A great amount of experimental work has been carried on on the Continent, in America, and in England, which goes to prove that formic aldehyde is a powerful antiseptic and germicide, its bactericidal action being equal to, if not greater than, that of bichloride of mercury.

It is at present very popular among the medical profession, its use being extended every day in the fields of histology, surgery, medicine, and hygiene.

It is rapidly superseding the older antiseptics, such as carbolic acid, perchloride of mercury, and others. Its advantages are:

1. It is non-poisonous and non-corrosive.
2. It can be used in the form of vapor, which, being of low specific gravity, is diffusible, and mixes well with the air.
3. It has no action on clothes, textile fabrics, leather goods, and general household articles, or on metals, except iron and steel.
4. It is easy and clean in its application.

F. Aldehyde in the Disinfection of Rooms.—Besides being used as a general antiseptic and deodorant, it has been largely employed in the disinfection of rooms with success.

About two years ago, in the course of some experiments, I made the following observations:

1. Linen strips dipped in broth cultures of staphylococcus pyogenes aureus, and exposed in a sealed room with a capacity of 2,000 cubic feet to the vapor generated from twenty paraform tablets, showed no growth after six hours.
2. Half to one per cent. formalin solution killed a pure culture of staphylococcus pyogenes aureus, bacillus anthracis, bacterium coli communis, bacillus typhosus within thirty

minutes to an hour; and ever since I found formaldehyde to be the most efficient and reliable in the disinfection of rooms in the sanatorium with which I am connected.

F. Aldehyde in Pulmonary Tuberculosis.—The next step in the progressive use of formaldehyde has been its application in the case of throat and lung disease—especially in pulmonary tuberculosis—in which disease encouraging results have been obtained by medical men.

Dr. Lardner Green of Salisbury, was almost the first in this country to bring before the medical profession the desirability of using the inhalation of formaldehyde in early cases of pulmonary tuberculosis.

Dr. William Murrell, of London, in his report to the Scientific Grants Committee, 1899, related twelve successful cases that have been treated with the vapor.

On the Continent, Professor Cervello, of Palermo University, has given considerable attention to this subject, and has invented an apparatus for the production of formaldehyde gas.

My Observations.—I began treating patients with the drug in 1899, and have continued my clinical observations ever since.

I have already published the results of *seven cases*, which are briefly as follows: Three were cured, two were benefited, and in two others the results were not conclusive.

I have now to record the results of *fifteen cases*. Before so doing a few words as to the apparatus used would be desirable.

Formaldehyde was used:

1. In the form of gas, and
2. Formalin (40 per cent. solution).

The gas was generated in two ways:

(a) *The Dry Method.*—In this method paraform tabloids—called dry formalin—were placed on a metal tray over a methylated spirit lamp (alformant lamp).

The principle of this method is that the hot moist products from the combustion of the spirit, acting upon the tabloids, convert them to formaldehyde gas.

(b) *The Moist Method.*—In this method, in addition to the above apparatus, there is a boiler for generating steam, which, mixing with the formaldehyde vapor, renders it more diffusible and penetrating in its action. Of these two methods the latter is the more efficacious.

Method of Using.

1. The vapor is administered either in the patient's bedroom or in the inhalation room, which faces south, having plenty of sunshine; for the drier the atmosphere the more the vapor is generated, the greater its penetrating power. The doors and windows are partially or wholly closed, the lamp is lit, the boiler is filled with warm water, the paraform tabloids are put in, the patient sits in a lounge chair or lies in his bed and inhales the gas.

The vapor at first causes irritation of the eyes

*From advance sheets furnished by our representative at the Congress on Tuberculosis, London.

and nostrils, which passes off after a few minutes. The inhalation is continued for one, two, or three hours, when the doors and windows are again opened.

2. The aqueous solution of the vapor or formalin (40 per cent.), as it is called, is used in two ways.

- (a) It is used (6 to 10 per cent. solution) in an inhaler, which the patient places over his mouth, using it from four to six hours in the course of the day.
- (b) It is also used in the form of fine spray, or in a nebuliser, at a strength of 6 to 10 per cent. solution mixed with glycerine.

The patient uses both these methods in the course of the day, either when he is in the open air or in his day shelter with doors and windows wide open.

Results.

Fifteen patients (twelve men and three women) have been treated in this way for three to five months. All of them have been my patients in the sanatorium, undergoing the open-air treatment for six to eleven months. They have not had any special medicine beyond an occasional pill or a mixture to correct indigestion, consequently the results have not been complicated in any way by the treatment.

Of the fifteen patients:

Five (all men) were completely cured. No physical signs or bacilli were found when they left. They have ever since continued to be in good health.

Seven (six men and one woman) were almost cured; i. e., a few dry crepitations and a few bacilli remained when they left, but they have been in good health and have followed their different avocations.

One (a woman) was slightly benefited.

Two, in the rest it had very little effect.

Of the five who were completely restored to health, three had affection of one lung, one had a large cavity in the left apex, the other had marked signs of breaking-down of both lungs.

Of the seven who were nearly cured, two had cavities of one lung and consolidation of the other, one had empyema complicating pulmonary tuberculosis, and the rest had more or less extensive affection of both lungs.

(Some Typical Cases in Detail.)

Remarks.

1. The results of the treatment to my mind have been very satisfactory, and I would strongly urge that the drug should be given a fair trial in every sanatorium where the open-air treatment is carried out.

2. It should be systematically and persistently used; and some one enthusiastic in the treatment should take charge of the apparatus, for the apparatus requires to be kept clean, and the lamp, etc., need careful supervision every day; any neglect would bring about indifferent vaporisation, and the results will be more or less a failure.

3. Though formaldehyde is non-poisonous, it has-
tens coagulation of blood. Hence the injection of

formalin directly into the veins and tissues of the body complicates the process of treatment and adds a certain amount of risk. Besides, it is not necessary, as the efficacy of the drug can be equally well obtained by simpler methods of some form of inhalation discussed in this paper.

In *chlorosis* the blood is pale and of low specific gravity, but its coagulation power is normal. The red bloodcorpuscles have their resistance weakened and the serum possesses a globulicidal action. Chemically, the serum is normal, but in the cellular elements there is a notable diminution of the potassium salts and of the chlorides and a slight diminution of albumin. The power of absorption of oxygen by the blood is lessened and the activity of the reduction of oxyhemoglobin is very pronounced. The chief lesion, however, is the excessive reduction of the amount of iron in the blood. The enormous lowering of the percentage of hemoglobin. Histologically, the red cells are diminished in number as well as in their globular value. Microcythemia, poikilocytosis and polychromatophilla are also present. The number of hematoblasts is more than double, whilst nucleated red blood corpuscles are very rare. Léger has never seen red bloodcorpuscles with basophilic granulation nor leukocytes with iodophilic granulation. There is a slight leukocytosis, a little more than 10,000 per cmm. The relation of leukocytes to the red bloodcells which is always diminished is sometimes very great. The polymorphonuclear neutrophilic leukocytes are increased in number absolutely and relatively. On the other hand, the lymphocytes are diminished. The large mononuclear leukocytes, the eosinophilic polymorphonuclear leukocytes and mast cells undergo no appreciable numerical change. Milk serum injected subcutaneously in chlorosis increases the number of red bloodcorpuscles, raises the amount of hemoglobin rapidly and then maintains it at a mean figure which does not increase with the continuation of the treatment. The leukocytes are increased in number at first, but soon return to the original figure. The lymphocytes, on the other hand, diminish at first and then increase in number, while the other types of leukocytes are not sensibly altered. In the treatment of the condition by iron protoxalate the red blood corpuscles, as well as the percentage of hemoglobin, increases, but whilst the red bloodcorpuscles increase very rapidly at the beginning of the treatment, later on increase is slower, while the increase in the percentage of hemoglobin at first slightly shown, subsequently becomes much more marked. The polymorphonuclear neutrophilic leukocytes diminish in number whilst the lymphocytes increase. Treatment by sodium cacodylate lowers the percentage of hemoglobin decidedly and at the same time it increases the number of red bloodcorpuscles a little or not at all. Leukocytosis is appreciable and affects the polymorphonuclear neutrophilic cells and the mononuclear elements. The lymphocytes diminish in number. Rest in bed gives the same result, but in a less degree, as the protoxalate of iron. The iron preparations give the best results in the treatment of chlorosis. [J. M. S.]

Recurrent Hemichorea Cured by Hypnotic Suggestion.—

Dr. Paul Faraz reports a case of hemichorea, which has existed for three months, cured in one seance by hypnotic suggestion. The patient, a girl of 19, had her first attack of chorea, also affecting the right side, three years before, when she was suddenly sent for, as her mother was very ill. It took her over six months to recover. This year her mother died. The hemichorea appeared again immediately. Besides, there was marked hemianesthesia, also right-sided, and insomnia. She dreamed a great deal. Having made the diagnosis of hysterical hemichorea, Faraz promised to cure her in one sitting. He then hypnotized her and told her that the movements would disappear when she awakened. When she awoke, the movements had gone. Faraz told her that she was cured, and showed her how well she could move her hands, etc., voluntarily. Massage and electricity soon effected a perfect cure. Faraz also suggested pleasant dreams, the disappearance of all pain, and regular evacuation of the bowels, all of which occurred. She has gained 15 pounds in two months, and is now perfectly well.—(*L'Independance Medicale*, 1901, No. 22). [M. O.]

SLOW PULSE. By Robert T. Edes, M.D., of Boston, Mass.—Continued.

TABLE I.

Cases of permanent slow pulse with nervous syncope or dyspneic paroxysms, in which autopsies were made.

Reported by	Sex and Age	Pulse	Heart	Paroxysms	Origin or early symptoms	History	P. M. appearances in heart and vessels	P. M. appearances in brain and nervous system	Remarks
1. Prentiss, Tr. Assoc. Phys., 1880.	M. 51	36-42	Sounds normal-sphygmograms.	Faint short loss of cons; cyanosis	Tobacco; malaria; dimming; faint g. early paroxysms 1887.	Impr. Relapsed. Co. continued paroxysms. Delirium death 1880.	No fatty degen. No atheroma coron. Aorta dil.	Nothing remarkable	Ganglions no change. Slight swelling of card branches of vagus
2. Duncan, Med. Commentaries.	M. 51	26-9		Exhaustion; fainting; convul. attacks.				Watery fluid in ventricles, tetral. appearance some parts of pla.	
3. Gibson, Lond. Med. Gaz. 1858-59, vol. 1.	M. 70	22-46	Very feeble in paroxysms	Pallor, cyanosis; loss of consciousness	Sl. at 20 years before	Last eight years fits more frequent. Died in one.	Sl. atheroma coron. Heart large Aorta dil. Atheromatous lower part.	Congested	
4. Holberton, Med. Chir. Trans. vol. XXIV.	M. 61	22-7 60 before accident		Fainting fits. Dyspnea.	Fall from horse. Injury to neck.	Died in syncope 7 years later.	Large and weak. Lining of vessels thickened	Congestion of mediastinal prolongata from enlargement of oesophageal process	R middle cervical ganglion unusually large
5. Cain, Charleston Med. S. 1880.	M. 45	31 to 38	Sounds normal.	Pseudo apoplectic.	3 years before, exposure (?) with fainting.	Lat. dyspnea, palpitation, exhaustion, increased frequency of fits. Died after 2 years.	Much fluid in pericardium, fainter. Aorta congested	Healthy	Slight
6. Jacobi, Tr. Assoc. Phys., 1880.	M. 51	28-48	Much changed, faint or 2 sounds.	Syncope.			Atheroma of art. Fatty degen. of heart. Heart ganglia enlarged hard & calcareous.		
7. Edes, See text, Case 1	F. 50	56-11	Irreg. weak, area not enlarged.	Syncope; loss of cons. at times.	Shocks, grief, faint spells.	Paroxysms continued. Died in one.	No fatty degen. Very little atheroma Coronaries normal	Normal	
8. Stackler, Rev. de Méd. p. 204.	F. 53	40-28	Two cardiac revolutions to each cardiac beat Irreg. soft, sibilant.	Heart stopped then vomited. Pain; sometimes loss of cons. Cyanosis.	Previous to 1880 nervous attacks with sometimes loss of cons. Probably hysterical.	For 5 or 6 years palpitation, pain in pericardium.	Milky patches on tunica involving 1 vagus. Vagus hard red, swollen.	Tumor of mediastinum involving 1 vagus. Vagus hard red, swollen.	By microscope no alteration of vagus fibers
9. Lepine, Lyon Med. vol. XLIII, p. 313.	M. 65	34	1st complete beats followed by 1 or 2 pair calm sleep. Sometimes a 4th impulse with 1st venience at first sound.	Loss of cons., like fol. by 1 or 2 pair calm sleep. Not followed by any incon. Impulse with 1st venience at first sound.	15 attacks in 18 months.	Late depression for half a day after attacks. Died suddenly. Slight convulsion of face	Narrowing of vertebral canal with prominence of also physis suff. to cause some comp. of r. side of protuberance and bulb.		
10. Tripiet, Lyon Med. vol. XLIII.		60 60 to 12		Epilepsy.			Completely negative		
11. Gibbings, Lancet, 1881, Feb. 11	M. 66	Intermittent ever since he can remember 44-12	No evidence of disease	1st indication of recurrence failure of the head, then epileptiform, face pale. Patient had an aneur.	Anxiety, worry	Improvement re-lapse, fainting, death	Arteries remark at ably free from atheroma. Valves and muscular walls healthy. Coronaries previous	Other organs normal	Autopsy by Moxon atrophied (did not grow)
12. Claylaugh, N. Y. Med. J. 1880.	F. 59	40	Palpitation.	Epileptoid	Bronchitis (Grippe?)	Better than usual, 2 or 3 days. Died suddenly.	Novely dis. Coronary deposits throughout its course. (See last column)		Roof of arch of aorta chronically inflamed. Small calcareous patches in aorta. Pulmonary vein acutely inflamed.

Cases of permanent slow pulse with nervous syncope or dyspneic paroxysms, in which autopsies were made

No.	Reported by	Sex and Age	Pulse	Heart	Paroxysms	Origin of early symptoms	History	P. M. appearances in heart and vessels	P. M. appearances in brain and nervous system	Remarks
13	Sendler Chl. f. Klin. Med. 1892, p. 612.	F. 55	60-77-24-22	Systolic murmur	Fainting fits.	Gen'l debility and fainting fits 6 mos. 30.	Increased pulse to beat large, imbedded in fat. Myocard flabby. Valves norm. Narrowing of pulm. artery by fibroma.		Well brain congested.	
14	Haude & Lurot Soc. Méd. des Hôp. de Paris, 1890.	M. 72	Diag. of slow pulse; 36.	Some "faux pas."	Vertigo, some times unconscious, a few times convulsions.	Not good habits. Sudden attack in 2 syncope, some consciousness. Con- times loss of consciousness. Sudden death.	Frequent vertigo. Sudden attack in 2 syncope, some consciousness. Con- times loss of consciousness. Sudden death.	General atheroma of pulm. artery by fibroma.	Induration of small vessels in cerebral hem.	
15	Sirady Soc. Méd. des Hôp. de Paris, 1890.	M. 68	60-72-28		Epileptiform.			General arterio-sclerosis.	Carotids and arteries at base hard. No lesion of cerebrum. Cerebellum on cord. Both manifestly congested.	
16	Adams Publ. Hosp. Rep. 1877, Vol. IV.	M. 68	Usually 30. Slower than usual in attacks.	Oppression in breathing	Apoplectiform. Complete insensibility. No paralysis.	Athletic. Sudden faintness when walking.	Improvement. Col- lapse. Intermittent pulse. Died 3 days later.	At least 20 attacks in 7 years. Died in one. R. aur. much dil. Aortic valves thickened. R. ventr. fatty. Ven. very thin, covered with fat. Fat degen- coronaries normal. In ven. sl. hypert. Streaked with fat at one point near apex. Small patch atheroma. 1st part aorta.		
17	Robson Lancet, March 27 1897.	M. 38	70-24-20	Normal.	Faintness. Brief loss of cons. Slight tonic spasms.	Temperate, not fat. Winter cough, last two winters worse. Dyspnea.	Died suddenly. Syncope.	Larger than nat. Fat on surface walls of ventr. soft and friable. Aorta atheromatous. R. coronary esp.		
18	Parkes and Cadger Oman Med. Chir. Trans. XXXIII	M. 51	30 irregular	Slight, eulargement. 1st sound muf- fled.	Faintings, extreme short. Both muf- fled.	Fainting fits, frequent for 6 weeks.	Anemic.	Fibrous deposits in m. with L. cavity dil. wall atrophied. Columnar carneæ atrophied.		
19	Bence Jones Fr. Path. Soc. vol. VIII.	M. 53	Feeble 36-28	Sounds distant. Impulse feeble.	Fainting fits; some spasmodic action. Not perfectly insens.	Anemic.	Anemic.	Fibrous deposits in m. with L. cavity dil. wall atrophied. Columnar carneæ atrophied.		
20	Ugler Fr. Path. Soc. vol. VIII.	M. 40	48 Reg.	Action feeble. Sounds distant muffled.	Epileptic attacks.	Had had rheuma- tic fever following diarrhoea, epileptic attacks.	Anemic.	Fibrous deposits in m. with L. cavity dil. wall atrophied. Columnar carneæ atrophied.		
21	Regnard, Case 12. These. de Paris. 1890, p. 100.	M. 55	26	Sounds normal.	Vertigo, loss of consciousness, con- vulsions.	For four years ver- tigo, loss of cons. leptic attack with p. and respiration. followed by general in- convulsions.	Fatty overgrowth. Degeneration. Coronaries narrowed and atheromatous.		Edema of brain.	
22	Regnard, Case 16.	M. 20	25	Hypertrophy. Impulse violent. no souffle.	Dyspneic, anginous, syncope.	Infantile paraly- sis; drunken dyspneic attack; sarcomatous syn- copal attacks.	Died in syncope.	Fibrous deposits in m. with L. cavity dil. wall atrophied. Columnar carneæ atrophied.	Brain (carefully examined) normal.	
23	Regnard, Case 19.	M. 60	20	P. small, average tension and force less.	Loss of consciousness.	For 6 years loss of consciousness with respiration; edema of glottis and convulsions.	Death by arrest of hypert. and dil. with chronic debility. Endarteritis, coronaries dilated but healthy.		Thickening and dilatation of vessels at base of brain.	

TABLE I (continued).

Cases of permanent slow pulse with nervous syncopal or dyspneic paroxysms, in which autopsies were made.

No.	Reported by	Sex and Age	Pulse	Heart	Paroxysms	Origin or early symptoms	History	P. M. appearances in heart and vessels	P. M. appearances in brain and nervous system	Remarks
32	Jona Riv Ven d Med 1898	M 46	26-30-22	Friction sound, sounds distant; dull. More frequent than radial, almost exactly double.	Epileptiform. Cyanosis. Extreme dilatation of pupils, came afflicted with dyspnea, oppression, prostration.	P. in health 75. Became afflicted with severe attack	Died in unusually	Rough patches on pericardium, 1 vent. sl. distended walls hypertrophied. Sl thickening of aortic valves. Mitral stenosis. Coronary No atheroma anywhere; some scleroses cardiac muscle.	Slight edema of brain	
33	Cornil Gaz des Hop 1875 p 500	M 75	25-30	Heart same	Dyspnea, some convulsive movements. Consciousness lost sometimes lost.	Weak. Emphysema and bronchial catarrh.	Lost appetite. Vom pale.	Size normal; no lesion orifices; complete fatty degeneration. Aorta and valves sl. atheroma tons.	Brain pale. Adhesions of dura mater of pancreas	Fatty degeneration of pancreas
34	Worthington Lancet 1890 II, 2, 326	M 65	75-80 or less		Dyspnea prostration.		Died in unusually severe attack.	Fatty. Valves normal.		

TABLE II.

Cases of slow pulse, without well marked paroxysms, in which postmortems were made.

35	Goddard Rogers, Canstatt's Jbb. 1877, p 199.		18-28					Cicatrices in septum.		
36	Veo Lancet. 1872, p 913.	M 45	36	Apex (open) in natural position. Loud systolic murmur, then 2 short sounds.				Pericardium uniformly adherent; mitral stenosis; aortic valves thickened; heart flabby. Right ventricle thin.		
37	Spencer, Prentiss, Case 37 Boston Med. and Surg. J 1881.	M 50	Much slower than normal.		Accident, fell on neck and head	Complete sensory and motor paralysis below head. Died in 18 hours.			Dislocation between 2nd and 3rd cervical vertebrae.	
38	Abercrombie, Case CXVIII Dis. of brain and cord.	M. Soldier	Slow languid.		Pain in back of head; giddiness; violent headache.				Vessels of cerebellum turgid. Coagulum under cerebellum	
39	Abercrombie, Prentiss, Case XXIV	F. 6	30-40		Headache and right side convulsed				Hydrocephalus and tubercles in left cere-brum.	
40	Bright's Med. Reports 35, Prentiss, p 135, XXV	M 49	39-42 Later 11-78		Had had blows on head; headache.	Giddy, wandering, drowsy.	Heart small; valves normal.		Brain adherent at right temple and indurated in spots	

TABLE II [continued].

Cases of slow pulse, without well marked paroxysms, in which postmortems were made.

No.	Reported by	Sex and age	Pulse.	Heart	Paroxysms	Origin or early symptoms.	History	P. M. appearances in heart and vessels	P. M. appearances in brain and nervous system	Remarks
11	Abercrombie, pp. 89, Prentiss, Case XXVIII	16 months	Remarkably slow.			Injury to back of neck.	Paralysis; convulsions. Died in fit.		Fluid in the ventricles. Abscess at summit of medulla where it was crossed by the pons.	
12	Prentiss, Case XXIX	M. 17	18		Respiration 13.				Fracture between 11th and 5th cervical.	
13	Prentiss, Case XXX	M. 20	10-50			Fall; Complete paralysis.	Lived 3 days		Fracture 5th cervical. Compression of cord with sanguinolent striae.	
14	Schuh, Med. Gaz. vol. 28, pp. 396, Prentiss, Case XXXIII	M. 35	30			Fall, neck deformed, painful. Died on 12th day.			Luxation between 11th and 6th cervical	
15	Schuh, Med. Gaz. vol. 24, Prentiss, Case XXXIV	M. 35	Feeble and slow.		Respiration feeble and slow.	Fall, palsied.			Luxation between 5th and 6th cervical softening of medulla.	
16	Abercrombie, pp. 204, Prentiss, Case XXXV	M. 35	30-40 Shortly before death.			Gradually palsied 2 years. Sight and right limbs; short time before death pulse and respiration became slow lost speech and power of swallowing.	Atrophy of two years. Sight and right limbs; short time before death pulse and respiration became slow lost speech and power of swallowing.		Brain and viscera most healthy; cervical cord hard and like cartilage. Membranes red.	This seems to have been subacute anterior poliomyelitis with bulbar paralysis.
17	Nieden Tr. Clin. Soc. London; vol. VI., pp. 75.	M. 60	Gradually fell to 40.			Fall down stairs. Progressive lowering of pulse and fluid blood. Complete paralysis, lower extremities, chest and greater part of trunk.	Distended with blood.		Dislocation without fracture of 1st dorsal; compression of corresponding portion spinal cord.	
18	Stokes, case 2 Dub. Quart., 1846, pp. 75.	M. 50	Very slow.	Valvular murmurs.		Anemic.	Death apparently from syncope.	Aortic valves thickened; ventricle soft and flabby; covered by very thick layer of fat.		
19	Deboise, Soc. Méd. Hôp. de Paris, 1888, pp. 111.		32		Nothing said of an epileptiform attack				Bulb perfectly healthy. Examination of pneumogastric nuclei—nothing abnormal.	
20	Hutchinson Lond. Hosp. Rep., 1866.		40					Fracture of cervical spine.		
21	Tyrrell, Lond. Med. and Phys. Journal.	M. 24	10-55-70-85 20			Fracture 4th cervical. Small clot on cerebellum; supraclavicular nerves involved in clotted blood.			Blood on surface of dura extravasation in cord.	
22	Pope, Veterinarian 1845.	Horse	10	Strong bounding rattle which made lug and horse fell whole chest shake down.			Killed		Dropsy of spine in cervical region.	

TABLE III.
Cases of slow pulse, with or without paroxysms, resulting fatally, but in which no autopsies were made

SEPTEMBER 7, 1901

\$3.00 PER ANNUM

Pregnancy and Small-pox.—The recent observations of Roger constitute a valuable addition to our knowledge of the placental transmission of disease to the fetus. It is now generally admitted that there are certain maternal diseases which affect the embryo and fetus, resulting either in the death of the latter or in the clinical manifestations of the disease immediately or shortly after the birth of the child. Antenatal and congenital syphilis is the most striking instance of the kind. For quite a long period the transmission of tuberculosis in this manner was denied, but recent careful investigators, Lehmann, Neil, Kynoch, Charrin, and others, have definitely settled the possibility of tuberculous infection of the fetus. Roger now gives an interesting review of a series of cases in eleven pregnant women observed by him in his small-pox service at Aubervilliers, all of whom gave birth to children who appeared to be absolutely well, but who all presented marked subnormal temperature, in one instance 28°C ., in another 30°C ., and in another 31°C . Seven of the children shortly developed marked manifestations of small-pox, the symptoms appearing in a typical manner, beginning with an elevation of temperature, followed by the characteristic cutaneous eruption; three of the remaining four showed intense infection, the only symptoms being jaundice and subnormal temperature, with death four, six, and eleven days subsequent to birth. One child developed a scarlatiniform eruption, and only one of the eleven survived, the others dying in from two to three days after the development of the eruption. A more interesting and instructive series of observations could not be reported. From the accumulated literature on the subject of transmission of disease through the placenta from the mother to the child, it is evident that next to syphilis the exanthemata are most prone to affect the fetus *in utero*. It is also interesting to note that the association of the disease with the pregnant condition reacts unfavorably upon the mother. Maternal death is not infrequent under these circumstances, and in every instance in which a fatal termination does not supervene the mother passes through a most critical illness.

The mode of entrance of the morbid agent into the fetoplacental circulation is as yet a disputed question. It is probable, however, that access is gained through bacterial action, the germs rendering the placental villi less resistant to invasion, whereby both the microbes and their toxins pass the natural barrier at the choriodecidual junction. A curious fact which has been repeatedly proven on the autopsy table is that, as a rule, the infectious diseases do not manifest their characteristic visceral lesions in the fetus, probably because of the passivity of these organs during antenatal existence. The germs, however, may be detected in large numbers by bacteriological and microscopic examination. Such reports as that given by Roger cannot be too highly commended, inasmuch as they add to the meagre literature of what is evidently a most important but as yet imperfectly understood chapter of medicine.

Immunity in Typhoid Fever.—The subject of bacteriolysis and immunity, has of late been receiving its due share of attention. Dr. Mark W. Richardson, of Boston, has recently completed his studies upon this subject, dealing especially with typhoid fever. He has observed the effects upon the typhoid bacilli of typhoid blood-serum alone, and in combination with normal blood-serum. His investigations of the blood-serum of 41 typhoid patients were made at various stages of the disease and during convalescence, for the purpose of determining whether the blood-serum of typhoid patients is markedly antagonistic to the growth of the typhoid organism, and if not, whether the addition of normal serum would increase its power. Richardson acknowledges his indebtedness to Bordet and Ehrlich for the suggestion of adding normal serum which they used in producing their so-called hemolytic serum. Richardson concludes that nature produces a cure in typhoid fever through bacterial agents acting upon the specific organisms. These agents are produced especially by the cells of the lymphatic system, and appear in the blood in varying amounts. He makes the interesting observations that these protecting agents are at least two in number, one being a specific immune element and

the other a non-specific element or ferment. The function of the immune element is to bind the complement, or ferment, to the bacterial cell which is then destroyed. In order that recovery may take place, it is necessary that both the immune body and the complement be present together for them to be active, and this is not the case in the earlier and middle stages of the disease when the immune body alone is present. It is in the stage of convalescence that the normal element returns to the blood and the bacteriolytic action upon the bacilli begins. Richardson presents the theory that since this marked destruction of bacilli must set free an excess of typhoid-toxin contained within the bodies of the bacteria, this may be a possible explanation of the marked remission of temperature seen clinically during the fourth week of the disease. The addition of the normal serum to the inactive serum of the typhoid patient, tends to make that serum more powerful and to resemble the serum of the fourth week of the disease. Consequently Richardson states on theoretic grounds, that we should be justified in treating patients in the early stages of the disease with normal serum. An objection to this may be found in that in some cases the patient's blood will lack both the immune and normal elements. Some of these will have to be supplied. The blood of a normal individual may possess a destructive power upon the typhoid bacilli, due undoubtedly to substances similar to those found in typhoid serum. As Richardson states, the principles which he believes to hold true in the case of typhoid fever, may be true also of other diseases, and the field offers a most promising one for original research.

The Relation Between Gastric Conditions and Psychic States.—It is generally believed, at least by the laity, that a satisfactory condition of the stomach is conducive to mental quiet. Pron, in his *Paris Thesis*, calls attention to the close anatomical relation between the stomach and the central nervous system. This relation with the brain, he states, is direct and with the spinal cord is indirect through the sympathetic system. We should be inclined to criticize this statement of the anatomical connection and rather to state that the relation with the brain is direct through the pneumogastric nerve and with the cord is more indirect through the sympathetic nerve. However, the author may hold the opinion that the pneumogastric nerve is a part of the sympathetic system. This more or less direct union of the central nervous system and the stomach may serve as an explanation of the action of the solar plexus upon the psychic functions in health and in diseased states. Each variety of food makes a characteristic impression on the solar plexus,

through its terminal branches in the gastric mucous membrane, which is immediately transmitted to the brain. Hunger produces certain slight impressions in a healthy man; in certain dyspeptics hunger is exaggerated, and the absence of food renders the subject incapable of the least intellectual work and produces marked changes in his character. Fasting determines the appearance of hallucinations and of dreams relating to the act of eating. Inanition may produce delirium and insanity. Dyspepsia, all the different symptoms of which are governed by the solar plexus, which favors bad hereditary equilibrium of the nervous system, may produce serious psychical troubles that are at first intermittent, and later, continuous. The theory of autointoxication is powerless to explain certain of these troubles, which appear and disappear suddenly. And furthermore, authorities are not agreed upon the value that should be placed upon the toxicity of the gastric contents of dyspeptics. On the other hand, the reflex theory explains almost all the morbid phenomena; it is, furthermore, in accord with the development of the disease as well as of its course, which consists essentially in intermittent and periodic phenomena. We thus find that there are two theories advanced to account for the mental state of dyspeptics: one, the autointoxication theory, and the other, the reflex theory advanced by Pron (*Gaz. Heb. de Med. et de Chirur.*, June 2, 1901). It seems to us that neither theory is proved, but the rôle of the absorption of toxic substances is being more and more believed in as the cause of cerebral disturbances, and the reflex theory which has so long been accepted is gradually being replaced.

Gasterine.—Le Gendre first suggested the use of the pure secretion of the dog's stomach in therapeutics. (*Bulletins et Memoires de la Societe Medicale des Hôpitaux de Paris*, January 26, 1900.) Later Frémont, of Vichy, managed to prepare the drug, under the name of gasterine. Le Gendre (*Bulletins et Memoires de la Societe Medicale des Hôpitaux de Paris*, June 27, 1901) has used it in chronic dyspepsia when there is little or no pepsin present, with good results. It has been especially useful in vague prolonged cases of gastritis, in doses of from 4 to 6 tablespoonfuls daily. He has also employed gasterine in post-operative indigestion, in the gastric disturbances of pregnancy or abortion, and in mucomembranous enterocolitis. Sarrade stated that when the liver was large or there was great thirst, gasterine acted well. Daudé found much improvement following its use in a case of chronic hepatitis with persistent diarrhea. Rendu reported a case of gastric intolerance following pleurisy with thoracentesis, cured by gasterine. Frémont reported a case

of chronic enteritis due to insufficiency of the gastric juice, also cured by gasterine. Albert Mathieu and Laboulais (*Bulletins et Memoires de la Societe Medicale des Hôpitaux de Paris*, July 4, 1901) report in full 9 out of the 15 cases which they have treated with gasterine. There was hypochlorhydria in all. Two patients who had hyperchlorhydria could not take gasterine, as it caused burning, eructation, and vomiting. The authors believe that when no improvement follows its use, in cases with marked hypochlorhydria, cancer of the stomach is to be suspected. Diarrhea disappears as soon as gasterine is employed. They conclude that gasterine causes great digestive improvement in hypochlorhydric dyspepsia, whether neurasthenic in type or not. If it is well tolerated, it may produce temporary amelioration in cancer of the stomach. Their analysis showed that gasterine contains from 3 to 3.5 g. of free hydrochloric acid to the 1000. Gasterine acts not so much by replacing the gastric juice, as by stimulating pancreatic secretion. Soupault thinks that diarrhea due to gastric insufficiency, when treated with hydrochloric acid alone, will be cured in the same manner as by employing gasterine. All investigators agree in pronouncing gasterine a useful drug.

Yellow Fever Experiments.—It is reported that three deaths have occurred from yellow fever experiments in Cuba. This is, of course, most deplorable. The fact that these deaths demonstrate the truth of a scientific theorem is not sufficient compensation for them—although this truth is pregnant with consequences of the greatest moment to the human race, and is probably as well worth a human sacrifice as many another and less worthy cause that does not scruple to boast of its human martyrdoms. It is a source of supreme satisfaction to know that these deaths were entirely voluntary; that is, that the unfortunate victims were forewarned of the danger, and took the risks deliberately with the intention of securing immunity.

Major Gorgas is quoted as stating that the Sanitary Department is ready to immunize any person who desires to undergo the risk after a full explanation of it has been made. The conclusion is accepted (and the fact seems only too fully proved by these recent deaths) that the poison of yellow fever, whatever it is, can be conveyed by the mosquito. Certainly no further proof that calls for the sacrifice of human life, is required, and no further experiments on human beings should be tolerated—merely as experiments. In order to secure immunity, however, the case is different; and ethically is on a similar plane to the older method of inoculation for smallpox. That method was not only tolerated but

advised before the introduction of vaccination. It was based on the principle of choosing the lesser of the two evils. The person who submits to an infection with yellow fever from the mosquito stands a better chance, according to Major Gorgas, than the one who contracts the disease in the ordinary course, as the former receives care from the beginning.

fooling with Leprosy.—On quite a different plane, however, stands the enterprise of the St. Louis physician who is reported as intending to isolate himself with a leper in order to study leprosy. At last accounts he had taken a dramatic farewell of his family forever, and was about to immolate himself (figuratively) on the altar of science. We should like to tell him, if he were within ear-shot of us, that science does not want his sacrifice and will not be responsible for his folly. We have had enough of the Father Damien business. There is no need for it; and what is worse, it is not only fruitless but it is downright mischievous. Such a method of studying leprosy, or of caring for lepers, is quixotic in the extreme. It tends to make a mystery of the disease, and is barren of scientific results. That it causes the death of a fanatic or two is not of so much consequence as that it misleads public opinion as to the true methods of scientific medicine and hygiene.

More "Medical Chemistry."—A bulletin on bee-keeping, issued recently by the Pennsylvania Department of Agriculture, contains some peculiar information on physiological chemistry. After stating that the annual consumption of cane sugar in this country is sixty pounds per head per year, the following outline of the dietetic relations of this substance and honey is given.

"Excessive use of sugar has in its train a long list of ills, such as sour stomach and various forms of dyspepsia; it is also credited with being one of the causes of that dread visitant, Bright's disease of the kidneys. When cane sugar is eaten, it is changed into grape sugar by digestion before it can be assimilated. If too much of this work is thrown upon the stomach, it rebels and the work is passed over to the kidneys. If the kidneys are overtaken there is no other organ to which the work can be transferred, and a breakdown is the result."

It is further stated that honey contains grape sugar and by its use, therefore, no hard burden is brought upon the stomach or kidneys.

It is a pity that the author of the bulletin, who, by the way, has the title "Dr.," did not limit himself to explaining the establishment and management of hives, a topic with which he is evidently familiar. In a bulletin of this character, there is no occasion

for a dissertation on physiology or chemistry, but if such is introduced, it should be written in accordance with the known principles of the sciences involved.

The author seems to be ignorant of the fact that grape sugar is not invert-sugar, and to be also unaware that honey contains much matter other than sugar. It is also a question whether a material prepared by insects with uncleanly habits is suitable for food. Some claim is made in the bulletin for the high value of honey as a substitute for cane sugar, and even for butter, but this is only suggested and, very wisely, not put strongly.

Sister-in-Law Statistics.—There is no more convincing argument than an array of imposing figures presented to sustain or overthrow an asserted fact. Much of our accepted teaching is based on such numerical proof. There is, however, a growing tendency to gather much material that can have no statistical, or, as far as we can see, other value to science. The truthfulness of this statement has been rather forcefully brought to our attention by a recent series of questions issued by the Committee of Health Statistics of the Alumni Association of one of our most prominent and useful colleges for young ladies. No doubt the object of these questions was a laudable desire to ascertain the influence of college life upon the subsequent health of the student. We can readily appreciate the importance of a knowledge of a girl's general health and of the condition of her eyesight at different periods prior to and subsequent to the college course. Also, as to whether or not nervousness or insomnia had been noted before, during, or after the college life. There is, likewise, much interesting and valuable information to be derived from the menstrual histories of these girls before and after taking a college course. It is difficult, however, to appreciate the value of an accurate knowledge of the condition of health of the husband's relatives, especially as concerns "chronic catarrh," "malaria," "insanity," "brain-paralysis," "spinal-cord paralysis," and "rheumatism," it being necessary, as stated in the question, to specify which form of the latter the individual suffered from.

The knowledge of medical subjects that would be necessary to answer definitely such questions would tax the brain-energies of many second and third-year medical students, and would betray a morbid curiosity on the part of a young married woman. Again, it is most perplexing to establish any relationship whatever between the menstrual or general health of a school girl or college graduate and the uterine disorders of her husband's female relatives. This method of

transmission of disease, if such were possible, could hardly be included under the headings of continuity or contiguity of tissue, and surely not under the toxemias or blood-disorders, while heredity has no bearing at all upon the question. The height of unconscious irony seems to have been attained in the final paragraph of the pamphlet, a copy of which was sent, we understand, to each and every accessible graduate and undergraduate of the college mentioned. We quote: "If the answers to these questions do not appear to you to include all the important facts which should be taken into consideration in your own case, please add here any further statement which you may think desirable." Here might be included the varying conditions of health of casual friends and acquaintances, in order to complete the history of the student's physical condition. *Reductio ad absurdum.* We most heartily endorse the formulating of statistical tables of value, but we would urge the exercise of judgment in gathering data.

The Signs of Cavity Formation in Cases of Pneumonia Following Influenza.—The clinician is often much worried by the development of pulmonary complications during an attack of influenza in which the suggestion of a beginning tuberculosis can hardly be put aside. In some of these cases physical examination elicits signs that seem to indicate the presence of a cavity. Neumager (*Gaz. Heb. de Med. et de Chirur.*, May 12, 1901) calls attention to the fact that the progress of a case of influenzal pneumonia is not frank, that its onset is often insidious, and that convalescence is very slow and is accompanied by frequent and abundant sweats, asthenia and rapid emaciation. The diagnosis between tuberculous cavities and the pseudocavities of influenzal pneumonia is aided by the fact that the former develop slowly, whilst the latter are of rapid evolution, sometimes making their appearance within twenty-four hours. The signs of a true cavity often change their location and are likely to disappear after several days. If a genuine tuberculous cavity exists, the abundant, purulent and nummular expectoration will contain the bacillus of Koch. On the contrary, this bacillus is not present in the expectoration from a pseudocavity, and, indeed, the expectoration soon ceases. The cachectic appearance of a phthisical patient is not seen in one who presents the signs of pseudocavity formation, even when those signs persist for a long time after the pneumonia is cured. Signs of pseudocavity are accompanied by an irregular temperature, but more frequently by hypothermia, whilst the signs of true cavity are almost always accompanied by hyperthermia. The beginning of the affection, its course, the

pneumonic fever which will accompany the appearance of the signs of pseudocavity, the knowledge of an epidemic of influenza or of some concurrent cases of influenza, usually permit of a definite differentiation of the signs of pseudocavity from those of a true tuberculous excavation.

The Treatment of Malaria with Methylene Blue.—A. Ivanoff (*Moscow Dissertation; Trutch, Vol. XXII, No. 15*) found that methylene blue has the same specific effect on malaria as quinine, being however, less rapid in its action. In cases in which quinine failed, methylene blue proved curative and vice versa. The tertian form is the most readily influenced by the drug. The methylene blue destroys the protoplasm of the plasmodia without affecting the pigment. It also acts well on the nervous manifestations of malaria. The dose is 1 grm. 3 times a day, in capsules. [A. R.]

The Role of the Gonococcus and Gonotoxin in the Production of Gonorrheal Inflammations.—Z. V. Sovinsky (*S. Petersburg Dissertation, 1901; Trutch, Vol. 22, No. 16*) gives the following conclusions based on experimental work on the subject: (1) Injections of gonotoxin subcutaneously, into the cavities of the uterine horns, into the anterior chamber of the eye, conjunctival sack and abdominal cavity may cause pus formation; (2) The bodies of the gonococci possess slight pus forming properties; (3) Prolonged heating above 65°C. destroys the pus forming elements; (4) The addition of antiseptics to the cultures weakens the pus forming elements; (5) Concentration of a disinfected culture in vacuo has the same effect; (6) Gonotoxin is destroyed in the animal body. The pus formed within the cavity of the uterus has a tendency to become absorbed in time; (7) Gonotoxin diminishes in a large measure the resistance of the tissues; (8) The pus-forming organisms (the white streptococcus, the colon bacillus and the bacillus pyocyaneus) may prolong the duration of gonorrheal infection; (9) The chronic cases of gonorrhea cannot be explained by the action of gonotoxin which remained inclosed in a cavity. The living gonococci must be present, or the disease may be kept up by the other pus-forming cocci, but in that case it loses its specific nature; (10) Gonotoxin may be preserved in a cool place for a long time without losing its virulence. [A. R.]

The Surgical Treatment of Enteroptosis.—Dr. E. Lambotte discusses enteroptosis for enteroptosis, reporting four cases in the *Presse Medicale Belge* (1901, Nos. 24, 25, and 26.) He first performed this operation in October, 1895. It is rarely done because the diagnosis of enteroptosis is not easily made, and there may be ptosis of several of the other abdominal viscera besides. All other operations devised for this have been unsuccessful, except gastroenterostomy, gastroplication, and gastropexy, all three in the gastric form of enteroptosis. In most cases the splenic and hepatic flexures, one or both, are detached, and the meso-colon is elongated. Some venous stasis may be noticed in the most dependent part of the mesentery. Lambotte's cases were a boy of 10, and three women aged 33, 41, and 38 years. Glénard's great sign, the narrow colon felt as a cord upon the descending aorta, is by no means constant. Constipation occurred, with attacks of intestinal colic, beside the general symptoms of enteroptosis. For operation, the patient should lie upon her back, never in the Trendelenburg position until after the abdomen has been opened, and the position of the intestines noted. A median incision is made, and the intestines found. The colon is then attached by suture, at both splenic and hepatic flexures, to the abdominal wall, and the abdomen is closed. The patient is kept on her back for two weeks, the sutures being removed about the eighth or tenth day. His four operations were performed from two to four years ago, and all are as yet perfectly well. [M. O.]

Reviews.

Diseases of the Heart, A Clinical Text-Book for the Use of Students and Practitioners of Medicine. By Edmund Henry Colbeck, B. A., M. D., Cantab.; M. R. C. P., London; D. P. H., Cantab.; Physician to Out-Patients at the City of London Hospital for Diseases of the Chest, etc., etc. Methuen & Co. 36 Essex street, W. C. London. 1901.

Dr. Colbeck in his preface says "I should have profited more . . . had I possessed a better knowledge of the elementary and fundamental bedside features of cardio-vascular disease. It seemed to me at this time, and it does so still, that a book dealing with the clinical side of the subject of Heart Disease in a form suitable to the requirements of the student and newly qualified practitioner of medicine, would prove of very great service."

To write a book that shall have the merits of a Sanson, or a Broadbent, and be concise enough to be read by the student and busy practitioner and escape the glaring defects of a compend, is a most difficult task. Dr. Colbeck has succeeded admirably in his work, for while in certain portions of his excellent book the tone and conciseness of his sentences savor somewhat of a compend, this feature is rather to be commended than adversely criticised, because on every page and in every paragraph there are explanations enough to show the reasons for the somewhat dictatorial statements.

The arrangement of the chapters is good, leaving nothing to be desired except in one or two instances which will be noted, so that the reader, by a mere reading of the headings of chapters can easily find an account of the particular conditions he desires to look up. Add to this the excellent index and there is nothing left undone in the matter of convenience to the reader.

The volume has an excellent and attractive dress, the press work is of the first order, the publishers are to be congratulated upon this feature.

Among the particularly good statements contained in the book are the following:

Page 6: The areas of both the deep and superficial cardiac dulness are plainly set forth, and while the limits of these areas may not be concurred in by all observers as they are not by the reviewer, it is refreshing to see printed some statement as to the limits of these areas. Each individual I believe has a different conception, within certain limits as to the exact positions of the borders of the areas, and the various books on physical diagnosis published in this country do not throw much light on the subject.

Page 16: Methods of Diagnosis. The whole chapter is excellent. It shows to him who seeks for truth the only possible way in which an accurate diagnosis can be made. The author insists on a *history* of each case, embracing the symptoms and the cause, and then a physical examination of the patient. His statement that Inspection, Palpation, Percussion and Auscultation should be used in every case and in the order named, will be heartily approved by every teacher.

Page 32: The description of the method of differentiation between venous and arterial pulsations in the neck is clear and concise.

Pages 35 and 36. He insists on the value of the locations of the apex beat, in this as in all his remarks, showing the value of careful painstaking observation of ordinary signs so often overlooked in examinations of the heart, in the vain search for a cardiac murmur. The description of murmurs which begins on page 53, is most clear and he must be dull indeed who is confused and not charmed and enlightened by reading the chapters. One remark alone, page 61, "Unless considered in the light of previous observations, the loudness of a murmur is of little diagnostic or prognostic value," is worth the reading of the entire book, if its truth may be fully appreciated.

On page 143, he insists that in all cases which have manifestations of the rheumatic state such as arthritis, erythema, tonsillitis, etc., etc., the heart should be carefully and

repeatedly examined. How frequently this precaution is not taken by the practitioner.

On page 179, he says, "it is the effect of the murmur on the first sound of the heart on which attention should be mainly directed." A most wise admonition.

On page 201 the description of what in this country is called Flint's murmur, is made in concise sentences, as a part of the description of the murmur of aortic insufficiency, as it should be, and not talked of as a sound apart from one of the two great divisions of murmurs, diastolic and systolic.

On page 210, the author calls attention in an unmistakable way to the fact that a systolic murmur at the aortic cartilage is not indicative of aortic murmur in the great majority of cases, a fact constantly misunderstood by students.

On page 231 the paragraphs upon "The Conditions of the Cardiac Muscle" are excellent. It appears to the reviewer that they should have been placed first instead of fourth in order in the chapter.

The chapter on Functional Disorder of the Heart, is very properly the last in the book; it is excellently written. Among the less praiseworthy points in the book may be mentioned the following:

Page 11, the apex beat is described as in relation to the nipple line, surely not so accurate or stationary a point as the midclavicular line.

On page 20, the sentence, "Persons are more liable to suffer from the rheumatic manifestations of heart disease than other people" means certainly cardiac manifestations of rheumatic states.

On page 30, the statement is made that visible epigastric pulsation commonly means either enlargement of the right ventricle, or displacement downwards of the heart, and that accidental causes of epigastric pulse are neurotic pulsation of aorta, etc.

The reviewer believes that epigastric pulsation is much more commonly due to these so-called accidental causes than it is due to any organic change in the heart and that the statement in the book will lead to the error of a diagnosis of some organic disease when some functional disturbance only is present.

On page 48, myocarditis should be added as an important element to the list of causes of "Shortness of the left ventricular first sound, with diminution of intensity."

On page 72, the fact that the "bruit-de-diabie" disappears when the patient lies down is not noted.

On page 149 the impression is given that malignant endocarditis is very seldom seen as a primary disease, when as a matter of fact it quite commonly so occurs. He fails to mention the very great value of a blood count in the differential diagnosis of the conditions. Frequently a decided leucocytosis or its absence is the deciding point for or against a diagnosis of malignant endocarditis.

On page 175 the obvious error is made that the area of cardiac dulness is increased more to the right than to the left in mitral incompetence. Certainly the line extends much toward the left and is only increased to the right when the right heart begins to fail. The statement on page 169 that compensation in mitral incompetence is chiefly effected by a hypertrophy of the right ventricle will scarcely be agreed to by most observers.

On page 188 the term post-systolic is applied to a diastolic murmur as it is throughout the work. In this country the term post-systolic (Griffith) is applied to a late systolic murmur.

It will be noted in reading the descriptions of the various valvular lesions that a palpable thrill is described in each. Thrills doubtless can occasionally be observed in all lesions, but except in mitral stenosis they are certainly rare. To describe them as common is to lead to error.

In the chapters on treatment, the great value of the hypodermic use of drugs as compared with administration by the mouth is not noticed, nor is the extreme value of morphin hypodermically in some conditions given due weight.

In a work of this character it seems improper to devote forty pages to the especial consideration of hypertrophy and dilatation of the heart, when they could better be discussed when treating of valvular diseases, their chief cause.

On the whole the book is of very great value. The profession must always be indebted to its author for its clearness and conciseness and to the publishers for the quality of the press work. [M. H. F.]

Correspondence.

EAR, NOSE AND THROAT IN DISPENSARY PRACTICE.

By W. G. B. HARLAND, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal:

Dr. Packard in a recent number of the Philadelphia Medical Journal, calls attention to the difficulties surrounding the treatment of the ear in dispensary practice, and suggests some remedies. My own feeling has been that it is unwise to separate ear cases from nose cases in dispensaries. The diseases of each are so closely dependent upon one another that the treatment of one without attention to the other does not afford the greatest good to the patient. A patient will oftentimes be treated in both dispensaries thus losing the benefit arising from a consistent treatment by one person. In the hospital, in major cases, a separation can very properly be made. At the Presbyterian Hospital most of the suggestions advanced by Dr. Packard have been in force for sometime. A clerk at the entrance to the dispensaries makes a record of the name, address and other information concerning the person who seeks treatment, the amount of his wages, number of children, etc. The unworthy are in this way refused admission. The surgeon in charge makes a careful examination of every case of ear, nose and throat trouble, and a full record is made of conditions found. A short entry is made at every subsequent visit of the patient, noting treatment and results. Where a difficulty in diagnosis arises, or the condition does not improve, the patients are referred to the aurist, or to the laryngologist of the hospital. The examination then being a deliberate and thorough one, cultures are made in all suspicious cases, and tissues examined microscopically when necessary. A nurse calls in the patients and assists in various ways. She sterilizes tongue depressors and other instruments, an important matter sometimes overlooked in dispensary work. So far the results have been most satisfactory and compare very well with those obtained in private practice. In fact these measures were instituted as much for our own instruction as for the good of the patient; data gained under such favorable circumstances being of great value. It is necessary, as Dr. Packard remarks, that the authorities should realize the importance of the work done in the dispensaries and should afford every assistance in providing instruments and apparatus, etc., so that the thousands who come may receive the largest measure of relief.

SUPERSTITION IN HOSPITALS.

By WALTER C. GIBSON, M. D., of Utica, N. Y.

To the Editor of the Philadelphia Medical Journal:

In noticing a comment in your valuable Journal of August 24th, 1901, under the heading, American News and Notes, in re "Superstition Abolishes a Ward Number," allow me to say that such purility of sentiment emanating from New York State psychologists, is amusing in the extreme. Reaching the conclusion (*reductio ad absurdum*) to change a ward in the hospital, number "13," for the benefit of the patients, presents a new phase of curative powers employed by such hospitals. It might be suggested that in order not to lose the fatal number in question, especially for those who have "difficulty in figures," the number might be applied to the Mortuary, a thing which was done some years ago at the Utica State Hospital, New York.

COLLECTIVE INVESTIGATION OF THE INFLUENCE OF THE SILVER NITRATE INJECTIONS ON PHTHISIS...

By THOMAS J. MAYES, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal:

In 1892 the undersigned began a collective investigation of the action of cold in the treatment of acute pneumonia and there is reason for believing that this procedure which resulted in gathering four hundred cases of this disease thus treated, with a death rate not quite five per cent., was an important factor in calling attention to the utility of that treatment, and in introducing it to the profession of this country. That research was based on the conviction that no remedy can be called truly successful until it has

passed the exacting crucible of clinical experience, and it is now proposed to apply the same ordeal to the silver-injection treatment of phthisis, which, in a large hospital, dispensary and private practice, reaching over a period of three years, and during which many thousand injections were administered, has given me greater satisfaction than any other method that I have ever employed. In keeping with the above expressed feeling a cordial invitation is herewith extended to those members of the profession who have the inclination and opportunity to investigate this method of treating phthisis and to whom a reprint on the subject with full information and blanks to report cases, will be cheerfully sent on application.

TOXIC EFFECTS OF ACETANILID.

By FRANCIS T. STEWART, M. D., of Philadelphia.

To the Editor of the Philadelphia Medical Journal:

Within the past two weeks I have seen two cases which prompt me to write you concerning the danger of toxic effects from acetanilid when used as a dusting powder on abraded surfaces.

The first patient had sustained an extensive burn of the left lower extremity. I covered the raw surface with Thiersch's skin grafts taken from the right leg and thigh, and asked an assistant to dress the right limb while I completed the left. Early the next morning the patient became cyanotic, collapsed and unconscious. On investigating the cause for such an alarming and unexpected episode I learned that the right leg had been copiously dusted with acetanilid.

The second patient was a baby, aged four months, suffering from intertrigo of the scrotum, buttocks, and thighs. A neighboring physician advised a liberal application of the following powder: Calomel 3ss, bismuth subnitrate and acetanilid aa 3 ii. The following day intense cyanosis developed. With the first case fresh in mind, the cause of trouble was easily found.

Both cases reacted readily. I do not know of a fatality following the external use of this drug, but can conceive its possibility, especially if the patient be debilitated from age or disease.

In aseptic cases it has no place; in septic cases there are more efficient and less dangerous agents at our command.

Abdominal Tumors.—In *L'Indépendance Médicale*, 1901, No. 18, a clinical lecture by Professor Hayem, at the St. Antoine Hospital, is reported. He presented a woman of 66, pale, thin, and cachectic. Her abdomen has been increasing in size for 5 months; she has had alternately constipation and diarrhea; and the loss of appetite has been marked. A number of masses about the size of chestnuts are palpable in the abdomen. The spleen is enlarged, as are the inguinal glands. Her chest shows deformity due to the corset. There is mitral insufficiency; with subcrepitant rales upon the right side and friction fremitus over the right base. There is evidently a neoplasm, and from the tenderness, this is near the stomach. The form of the abdomen suggests pyloric stenosis. The age of the patient and the size of the tumors are against tuberculosis. There is no ascites. But her appearance is cancerous. The tumors felt are probably secondary cancers of the omentum. The primary tumor seems most probably to be in the stomach. To confirm this, the stomach contents must be examined. The prognosis is grave. Hayem advised injections of cacodylate of soda. [M. O.]

Airol in the Treatment of Ulcer of the Cornea.—Stasinski (*Nowiny Lekarski*, March, 1901) treats corneal ulcers in the following manner: Having anesthetized the eye by means of cocaine, he injects under the conjunctiva 1 c.c. of a solution containing hydrochlorate of cocaine 2 grm., sulphate of atropine 0.5 grm., chloride of sodium 5 grm. and distilled water 100 c.c. The floor and edges of the ulcer are then scraped with a sharp spoon, painted with a solution of iodine and dusted with airol, this being followed by compresses of boric acid solution changed every 8 to 9 hours. In mild cases the ulcer disappears within 24 hours.

[A. R.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Death of John D. Lankenau.—The veteran philanthropist, President and chief benefactor of the German Hospital as well as President and founder of the Mary J. Drexel Home and Philadelphia Mother House of Deaconesses, died on August 30th at his residence in Philadelphia. His death was due to apoplexy. John Dietrich Lankenau was born March, 1817, in Bremen, Germany. After a successful business period in Philadelphia, he soon distinguished himself for his philanthropy and the active assistance he rendered the German Hospital. In founding the Mary J. Drexel Home, he supported it at his own expense at from \$30,000 to \$40,000 a year. He has been at various times honored by the German Emperor. His personal qualifications which always marked him as a man of distinction will always be remembered by his many friends.

Smallpox in Philadelphia.—A mild form of smallpox exists in the Northwestern part of Philadelphia. In the territory bounded by Susquehanna and Erie avenues, and Broad and Twentieth streets, no less than twenty cases are reported. Rigid disinfection and quarantine are being maintained by the Board of Health, which has issued a statement urging that all persons that have not been vaccinated within the last seven years, be immediately vaccinated.

The Clinical Professorship of Nervous Diseases in the Department of Medicine of the University of Pennsylvania is vacant. Individuals desiring to be considered as candidates for the position may send notice of such desire to the Rev. Jesse Y. Burk, Secretary of the Board of Trustees, University of Pennsylvania, 400 Chestnut street, Philadelphia, Pa., before September 28, 1901.

Vital Statistics for Philadelphia for the week ending August 31, 1901:

Total mortality	410	Cases.	Deaths.
Inflammation of the bladder 3,			
brain 23, bronchi 3, kidneys 16,			
peritoneum 13, pleura 2, stomach			
and bowels 41, tonsils 1			120
Marasmus 20, inanition 22, debility 6			48
Tuberculosis of the lungs			37
Apoplexy 12, paralysis 3			15
Heart-disease of 21, dropsy of 1,			
fatty degeneration of 3			25
Uremia 14, Bright's disease 7, diabetes 3			24
Carcinoma of the breast 2, face 2,			
stomach 9, uterus 2, pelvis 2, liver			
2			19
Convulsions			9
Diphtheria	30		8
Brain-abscess of 1, disease of 2,			
dropsy of 1, softening of 3			7
Typhoid fever	153		8
Old age			9
Abscess of the lungs 2, alcoholism 3,			
asthma 1, burns and scalds 2,			
casualties 4, cerebro-spinal meningitis 1,			
cholera infantum 15, cholera morbus 1,			
cirrhosis of the liver 2, consumption of the bowels			
1, croup, membranous 1, cyanosis			
2, diarrhea 1, drowned 6, dysentery 3,			
fever, malarial 1, hernia 1,			
homicide 1, leukemia 1, locomotor ataxia 2,			
obstruction of the bowels 3, poisoning 1,			
pyemia 1, rheumatism 2, sclerosis, arterial 1,			
spine 1, septicemia 4, smallpox 2,			
sore mouth 1, sarcoma, neck 1,			
suicide 1, sunstroke 1, syphilis 1,			
teething 2, tumor, ovarian 1,			
unknown coroner case 1, whooping cough 6			

NEW YORK.

Westchester County Medical Association.—A special meeting of this association was held in White Plains on August 1st. A resolution adopting by-laws in conformity with those of the New York State Association was passed, and it was further decided to hold five stated meetings during the year.

Accidental Death of Dr. Dana.—Dr. Alfred A. Dana, of New York, while recently attempting to cross the Harlem Railroad tracks at Bronxville, was struck by an express train and killed.

The Medical Association of Central New York is at present holding a well attended meeting under the presidency of Dr. Lucien Howe, of Buffalo.

Malaria at Fordham Heights.—At Fordham Heights, in the borough of the Bronx, quite a severe epidemic of malarial fever is raging, and it is stated that mosquitoes have been more numerous and troublesome there this season than ever before.

American Public Health Association.—The twenty-ninth annual meeting of the American Public Health Association will be held at Buffalo, N. Y., beginning September 16 and continuing until September 21, 1901. Dr. C. O. Probst, of Columbus, Ohio, is the Secretary.

The Death of an Illustrious Surgeon.—Dr. Thomas Masters Markoe, the distinguished surgeon of New York, died on August 27th at his summer home at East Hampton, L. I., at the age of 83 years. Dr. Markoe retired from active practice several years ago, by reason of advancing years. He was born in Philadelphia, in September, 1819; and was graduated from Princeton in 1836, and from the College of Physicians and Surgeons in 1841. One of his first assignments was as professor of anatomy in a medical college at Castleton, Vermont. From 1852 to 1854 he was professor of pathological anatomy in the medical department of New York University. Through the war he served as a surgeon in the Union army, but returned to his teaching afterward, retaining from 1860 to 1870 the position of adjunct professor of surgery. For the next nine years he served as full professor, and during the rest of his active service he was professor of the principles of surgery at the College of Physicians and Surgeons. In these various capacities he became well known to very many New York physicians of the present day, and a considerable proportion of them had been at one time or another under his personal instruction. Since his retirement in 1890, he has borne the title of emeritus professor of surgery at Columbia. Dr. Markoe was also even more widely known to physicians by his authoritative work on "Diseases of the Bone," and by numerous technical papers. He remained up to his death consulting surgeon at the New York, Roosevelt, Mt. Sinai, Woman's, St. Mary's, Vassar, and Nursery and Child's Hospital. He was, in addition, a member of the County Medical Society, the Academy of Medicine, the Pathological, Medical and Surgical, and Surgical Societies; of the Society for the Relief of Widows and Orphans of Medical Men, of the Century Association, the Princeton Club, the Museum of Natural History, and the Metropolitan Museum of Art.

NEW ENGLAND.

Bequest to Cooley Dickinson Hospital.—By the will of Mrs. Elizabeth N. Thompson, widow of Dr. Austin W. Thompson, which has just been filed, the sum of \$25,000 is given to the Cooley Dickinson Hospital, Northampton, Mass., the bequest to take effect upon the death of Mr. Thompson's stepdaughter.

WESTERN STATES.

Dr. George C. Pardee, of Oakland, Cal., will be a candidate for the nomination for Governor before the Republican State convention.

Next Medical Examination in Iowa.—The next examination of candidates for certificates to practice medicine in Iowa, will begin at 9 A. M. Tuesday, October 22nd, in the offices of the State Board of Health, and will last two days.

A Serious Charge.—Certain physicians in Indianapolis, Ind., are charged with conspiring to declare persons insane in order to obtain the fees, and an investigation is being made.

Shepard's Sanitarium.—The Department for Mental Diseases of Shepard's Sanitarium, Columbus, Ohio, has now completed its seventh year of successful work. The new

additions to its buildings just finished, make its capacity 40 rooms, and give ample space for 20 patients and their management.

The Oklahoma Territorial Medical Association will hold its next meeting at Oklahoma City, November 13, 1901. R. D. Love, M. D., Perry, president; E. O. Baker, M. D., Guthrie, secretary and treasurer.

The State Board of Kansas.—The State Board of Medical Registration and Examination of Kansas has just been organized with the following officers and members: President, G. F. Johnston, Lakln; vice-president, E. B. Packer, Osage City; secretary, H. W. Roby, Topeka; Drs. Williston, Lewis, Cook and Hatfield.

D. I. Wolfstein, of Cincinnati, has been elected to the new chair of Mental and Nervous Diseases in the Cincinnati College of Medicine and Surgery.

Faculty Changes.—The following additional changes have been made in the faculty of the Cincinnati College of Medicine and Surgery: C. W. Tangeman has been elected Professor of Ophthalmology; H. Freudenberger, Professor of Pathology; Theodore Schmidt, Professor of Chemistry; and Mark A. Brown, Professor of Clinical Medicine.

Justin D. Lisle, of Paris, France, who is said to have discovered the microorganism which is the cause of syphilis, was formerly a resident of Springfield, Ohio.

To Prevent Malpractice Suits.—The physicians and surgeons at Anderson, Indiana, have agreed to refuse all services in surgical cases unless they receive an agreement from the patient or his family releasing them from liability in the event of any unsatisfactory results.

American Association for the Advancement of Science.—This body held its annual meeting for 1901 at Denver, Col., under the Presidency of Dr. C. S. Minot, of Harvard University. The Association proposes to change its time of meeting to the first week of January. Next year such of its sections as choose to do so will meet in Chicago at that time; but a regular annual meeting will also be held at Pittsburg in June. A new section was instituted, entitled: Section K, on Experimental Medicine and Physiology. The presiding officer chosen for the ensuing year is Dr. Wm. H. Welch, of the Johns Hopkins Medical School; and the Secretary is Dr. F. S. Lee, of Columbia. The presiding officer of each Section is known as a Vice-President of the Association.

SOUTHERN STATES.

Russell Springs Medical Society.—The ninth annual meeting of the Russell Springs Medical Society, Dr. J. H. Scholl, Jabez, Ky., secretary, was held at Russell Springs recently. The following officers were elected for the ensuing year: President, Dr. W. R. Grissom, Columbia, Ky.; vice-president, Dr. C. D. Moore, Cave Valley, Ky.; secretary, J. H. Scholl, Jabez, Ky. The Society adjourned until the first Thursday in August, 1902.

The Southern Surgical and Gynecological Association will hold its next annual meeting at Richmond, Va., Tuesday, Wednesday and Thursday, November 12, 13 and 14, 1901, under the presidency of Dr. Manning Simmons, of Charleston, S. C. The secretary is Dr. W. E. Haggard, Jr., of Nashville, Tenn., and the chairman of the committee of arrangements, Dr. George Ben Johnston, of Richmond.

Tri-State Medical Society.—The thirteenth annual meeting of the Tri-State Medical Society, of Alabama, Georgia and Tennessee will be held at the Tulane, Nashville, Tenn., Tuesday, Wednesday and Thursday, October 8, 9, 10, 1901. The officers are: President, Dr. M. C. McGannon, Nashville, Tenn.; vice-presidents, Dr. W. G. Bogart, Chattanooga, Tenn., Dr. Seale Harris, Union Springs, Ala., Dr. Michael Hoke, Atlanta, Ga.; secretary, Dr. Frank Trester Smith, Chattanooga, Tenn.; treasurer, Dr. Geo. R. West, Chattanooga, Tenn. The attendance promises to be large, and an unusually attractive program will be presented. The railroads will give reduced rates. Those intending to read papers should send titles to the secretary, Dr. Frank Trester Smith, Chattanooga, Tenn.

A Wise Sanitary Precaution.—It is stated that Dr. O. H. W. Rogan, Health Officer for Washington County, Md., has prescribed individual drinking cups for school children.

The Medical Society of Virginia will convene in annual session in Lynchburg November 5 and continue in session three days.

CANADA.

Obituary.—Dr. Overton S. MacDonald, at Toronto, Canada, August 8, aged 39 years—Dr. John Barnhart, at Toronto, Canada, August 9, aged 88 years—Dr. Edwin R. Bishop, at Brantford, Canada, July 24, aged 44 years.

McGill University.—The "Exhibition of 1851" scholarship in McGill University has this year been awarded to R. K. McClung, B. A. The scholarship is tenable for two years at £150 a year, and is for the purpose of encouraging research in industrial physics, mechanics, or chemistry. The Faculty of Medicine in McGill University is making extensive alterations in its library. When completed, it will occupy much more commodious quarters than it does at present.

The Canada Lancet has passed into the hands of the Ontario Publishing Company. It is not expected that there will be any change in the editorial management.

Canadian Cooperation.—The Canadian government has joined the United States in the crusade against tuberculosis by barring immigrants who are affected with the disease.

MISCELLANY.

Obituary.—Charles S. Myers, at Lancaster, Pa., August 25, aged 29 years—Dr. Thomas M. Markoe, at East Hampton, L. I., August 26, aged 82 years—Dr. J. D. Kieley, at Fitchburg, Mass., August 28, aged 44 years—Dr. James C. Trevey, at Travilah, Md., August 29, aged 63 years.

The Camphor-Eater.—It is surprising what a number of camphor-eaters there are amongst the well-to-do classes. The idea seems to prevail that this gum, taken in small and regular doses, gives a peculiarly clear creaminess of complexion, and scores of young women buy it for this purpose. The habit is, moreover, very difficult to cast off, for camphor produces a mild form of exhilaration and stupefaction; and in many instances where very large doses have been swallowed, the habit has become a sort of slavery. These camphor-eaters all have a dreamy, dazed and very listless air, and in most of them there is an ever-present longing to sleep, or, at least, to rest. Extreme weakness generally follows the taking of regular doses, and cases have been seen where it has been almost difficult to tell the effects from those of alcohol. As to the complexion—if a ghastly pallor be an improvement, camphor certainly produces it.—*Ex.*

Do We Drink Enough Water?—The *Sanitary Record* claims it is asserted that people drink too little water, especially in the summer season. When one considers for a moment the large percentage of water of which the body is composed—more than two-thirds—and the further fact that this water is being thrown off from the lungs, kidneys, bowels, and pores constantly. It would seem that no argument was necessary to demonstrate the above proposition that too little water is taken into the system to repair this loss. The free use of water of proper temperature—uncontaminated water—aids digestion, regulates the bowels, is helpful to the kidneys, preserves the contour of the body, and to a considerable extent is fat-producing. Water may be taken alone or with liquid food, such as broths, soups, etc. There are many who seldom drink water unless they are positively thirsty, who would drink it much more freely if it were modified in taste as well as in nutritive properties by the addition of a little unfermented grape juice, or in the form of lemon or orangeade. A cup of hot water with a little sugar and cream to remove the boiled taste, objected to by so many, is a great improvement over tea, coffee, or the much-lauded cereal drinks. We believe that much of the benefit that comes from visiting the most noted watering places is not so much because of any special medicinal property, as because of the free use of the water itself independent of any real or alleged mineral properties, combined with the rest. People go to drink the water and to bathe in it, and they drink it morning, noon, and night, and between times, and during the nights. As a result the stomach, bowels, kidneys, liver, pores, and even the blood vessels themselves, get a much-needed flushing, and the over-clogged machinery of life gets a fresh start, and the supposed mineral in the water gets the praise. We do not advocate the drinking of large quantities of iced water, since but little digestion will

take place until the contents of the stomach have reached the normal temperature of the body.

The Distribution of Plague.—A telegram from the Governor of Hong-Kong to the *Lancet* received at the Colonial Office on August 19th, states that for the week ending August 17th there had occurred 4 fresh cases of bubonic plague, together with 5 deaths. For the week ending August 11th 8 cases of plague and 3 deaths from the disease, all among the natives, have been reported from all Egypt. Six cases and one death were reported from Port Said, one case and one death from Hagizig, and one death out of the hospital at Alexandria.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended August 31, 1901.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended August 29, 1901.

PRESTON H. BAILHACHE, surgeon, detailed as delegate to represent the service at the meeting of the American Public Health Association to be held in Buffalo, N. Y., September 16-20--August 24, 1901.

A. C. SMITH, passed assistant surgeon, granted leave of absence for 1 day, August 21, 1901, under paragraph 181, Regulations, U. S. Marine Hospital Service.

W. C. Todd, acting assistant surgeon, granted leave of absence for 14 days from August 18--August 25, 1901.

- F. S. GOODMAN, hospital steward, granted leave of absence for 30 days from September 1—August 26, 1901.
C. A. WARHANI, hospital steward, granted leave of absence for 30 days from September 4—August 22, 1901.
L. P. HALL, hospital steward, relieved from duty at Boston, Mass., and directed to proceed to Vineyard Haven, Mass., and report to medical officer in command for duty and assignment to quarters—August 28, 1901.

RESIGNATION.

HOSPITAL STEWARD C. A. WARHANI resigned to take effect October 4, 1901.

Changes in the Medical Corps of the Navy. For week ending August 31, 1901.

- P. A. SURGEON R. M. KENNEDY, detached from the Bennington when placed out of commission, and ordered home—August 27.
P. A. SURGEON D. H. MORGAN, detached from the Monongahela, and ordered to the Naval Hospital, Newport, R. I., immediately for treatment—August 27.
ASSISTANT SURGEON R. T. ATKINSON, detached from the Washington Naval Hospital, and ordered to the Wabash, immediately—August 27.
ASSISTANT SURGEON A. W. BALCH, detached from the Wabash, and ordered to the Monongahela, immediately—August 27.
MEDICAL INSPECTOR D. N. BERTOLETTE, detached from the New York, and ordered to the Brooklyn as fleet surgeon—August 30.
SURGEON J. E. GARDNER, detached from the Brooklyn and ordered to the New York—August 30.
ASSISTANT SURGEON J. M. BRISTER, ordered to the Marine Brigade, Asiatic Station—August 30.

GREAT BRITAIN.

A Serious Outbreak of Enteric Fever.—The medical officer of the town of Raunds in Northamptonshire reports that seventy-five cases of enteric fever have occurred within two weeks. The disease which is of a very serious character has been traced to a polluted well supplying two hundred families.

The Sanitary Institute.—The next Congress and Exhibition of the Institute will be held in the city of Manchester in the second week of September, 1902, under the presidency of the Right Hon. the Earl Egerton of Tatton.

The Stewart Prize.—The Stewart Prize which is awarded every two years for researches regarding the origin, spread and prevention of epidemic diseases has been awarded by the Council of the British Medical Association to Dr. Patrick Manson for his work on the malarial parasite.

Small-Pox in London.—Seven new cases of small-pox and three deaths from the disease have been reported. Seventy-two persons are now under treatment.

CONTINENTAL EUROPE.

The Fourteenth International Medical Congress will be held at Madrid, April 23d to 30th, 1903. The general secretary is Dr. Angel Fernandez-Caro y Novillas, Faculty of Medicine, Madrid, to whom application may be made for further information.

Dr. S. Baudry, Professor of Pathology at the Lille Medical School, has been appointed Professor of Ophthalmology.

Professors Landouzy and Budin, of the Paris Medical Faculty, have just been made officers of the French Legion of Honor.

A New Phototherapeutic Lamp.—Dr. Sophus Bang, an assistant of Dr. Flinsen in Copenhagen, has invented an electric lamp for phototherapeutic uses, the bactericidal power of which is said to be ten times that of the ordinary arc lamp employed by Flinsen in the treatment of lupus.

The Use of Sugar.—The present tendency of physiologists and authorities on dietetics to encourage the use of sugar as an aliment has not failed to excite some controversy and adverse opinion. A recent article by von Bunge is in point. This author, starting from the common observation that children who eat sugar appear anemic and have bad teeth, reasons that as sugar contains neither iron nor lime, its free consumption, by supplanting these essentials, is damaging and should be discouraged. In noticing the views of Bunge, Professor Lepine, of Lyons, takes exactly the opposite view. He shows from Bunge's tables how little lime and iron is taken in our food, and

hence the improbability of enough sugar being ingested to make up any appreciable difference.

Dr. Paul Garnault, of Paris, has offered to test upon himself Dr. Koch's theory of the non-transmission of bovine tuberculosis to human beings. He has written to Prof. Koch, signifying his willingness to be inoculated with material from cases of bovine tuberculosis.

Prof. Renvers, Director of the Municipal Hospital Moabit, and who had treated the Empress Friederich, has been appointed a Medical Privy Councillor.

Professor Wilhelm Mueller, Chief of the Surgical Department at the Louise Hospital at Aachen has been appointed Director of the Surgical Clinic and Professor of Surgery at the University of Rostock.

Professor van Gehuchten recently received the Belgian Quintennial prize of 5000 francs for medical investigation, for his investigations of the brain and spinal cord. **Dr. Bataille** has been appointed Professor of Anatomy at the University of Rouen.

Death of General Coler.—Staff Surgeon General Coler is dead. He was an honorary professor at the University of Berlin.

On Amebic Enteritis in St. Petersburg.—V. M. Kernig and A. U. Ukke (*Russki Archiv Patologii, klinicheskoi meditsiny i bakteriologii*, May, 1901) present the following conclusions from the literature collated in connection with a case of amebic enteritis observed by them: (1) There are at least 2 forms of ameba coli differing but little morphologically from each other; one form, however, is pathogenic to man and cats, the other is not. (2) The endemic form of tropical dysentery is always caused by the variety of ameba which is pathogenic to cats; the same is true of sporadic cases and exceptional slight epidemics in our latitudes, the most important exception, according to Ogata being Japan. These cases of amebic dysentery or amebic enteritis are characterized by the predominant affection of the submucosa of the large intestines, more frequent formation of hepatic abscesses and a tendency to a chronic course. Special emphasis is laid on the facts that: (1) ameba are present only in dysenteric ulcers and are absent in tubercular and typhoid ulcers; (2) they appear in the abscesses of the liver which accompany almost only the epidemic form of dysentery; (3) Kruse and Pasquale succeeded in causing dysentery in cats by means of the pus from an hepatic abscess in which neither the microscope nor cultures disclosed any other organisms except ameba; (4) all efforts to produce dysentery by inoculations with the various bacteria found in endemic dysentery proved futile. [A. R.]

On the Treatment of Progressive Cardiac Weakness in Acute Infectious Diseases.—P. W. Lubomudroff (*Meditsinskoie Obozrenie*, May, 1901) employs subcutaneous injections of salt solution to overcome the approaching heart failure in the course of acute infectious diseases. The strength of the solution is 0.9%. It is injected at body temperature by means of Prof. Diakonoff's apparatus which consists of a graduated glass vessel connected with a double bulb on one side and a bifurcated rubber tube on the other. The latter is supplied with two hypodermic needles which are inserted under the skin. The solution injected is absorbed in 2 to 3 hours. It acts as a powerful cardiac stimulant, having been found superior to the other drugs commonly employed. It is especially useful in dysentery, permanent recovery having followed its use in a number of cases. In typhoid fever the effects are less marked and usually transient, but even in this disease a few desperate cases of collapse and approaching dissolution were restored to life. The author also used injections by the rectum of solutions (½ to 1%) of Prof. Pel's physiologic salt tablets. These represent all of the osmotic elements of the blood serum, consisting of Na-21.51%, NaO-11.02%, K²O-4.61%, CaO-1.38%, MgO-0.21%, Cl-33.09%, CO₂-17.79%, SO₃-2.39%, PO₃-1.74%. The renal injection of this salt, although weaker in its effect, presents the advantage of being easily applied. [A. R.]

5. The Fallacy of the Permanganate Disinfection of Wells (Hankin's Method). M. L. DHINGRA.

1.—Houston opened a discussion on the public health aspects of enteric fever at the meeting of the Section of State Medicine of the British Medical Association. He is forcibly struck by 3 things: (1) That, notwithstanding the progress of science and the great efficiency of the public health service, we find ourselves at the beginning of a new century unable to stamp out a disease which is, nevertheless, still classed as a preventable one. All that we can say is that the mortality from it is less than it was some years ago. (2) That the efficiency of the army medical service, although high, has failed to prevent the British troops in South Africa from suffering from enteric fever to a deplorable extent. (3) That during the last few years some notable discoveries have been made in connection with the bacteriology of enteric fever and fresh light has been thrown on the modes of dissemination of the disease. Among the notable discoveries in relation to the bacteriology of the disease the author spoke of the agglutination phenomenon, the methods of differentiating between the bacillus coli communis and the bacillus typhosus and the isolation and the vitality of the latter organism. Among the recent additions to our knowledge of the modes of dissemination of the disease, reference was made to water, milk and shellfish as sources of contamination, to the soil, to flood water, to sewer gas, ground air and ground water, to sewage, to dust and flies, to sewage effluents, to typhoid bacilluria, to fried fish and infested mangles in relation to the spread of the disease. The author spoke of the incomplete results of preventive inoculation, of the use of the urotrophin in typhoid bacilluria, of the serum diagnosis of the disease and of the sterilization of the drinking water in relation to prophylaxis. The general measures for the prevention of the disease are (1) to protect the water supply from excremental pollution, (2) to see that all articles of food are free from objectional contamination, (3) to see that the drains and sewers are kept in good order and (4) to disinfect the stools, the urine, and the soiled linen of enteric fever patients. Dixey discussed the vital statistics of enteric fever. He finds that the death rate from enteric fever in London is a fluctuating one, but that, on the whole, it has materially diminished, the most marked descent having occurred about 16 years ago. The seasonal relations of the disease remain fairly constant from year to year, but there seems to be a tendency, at least in years of low general prevalence, toward a progressive lessening of the autumnal maximum. A comparison between London and New York in respect of their climate and enteric death rate indicates that some of the meteorological conditions, especially perhaps temperature, are factors in the activity of the enteric infection. The relation, however, is not of such a kind as to make itself apparent from year to year in one given locali-

ty. It is probable that the diminution in the death rate is really somewhat greater than it appears to be from the inclusion, in former years, of enteric cases under other heads. The case mortality of typhoid fever is almost stationary and seems likely for the present to remain so. Handford is convinced of the importance of direct infection in typhoid fever, not merely as an interesting clinical fact, but also as a widespread power for evil, especially in the small and crowded homes of the poor. Smith referred to the outbreak of typhoid fever in York, in 1900. Careful inquiry failed to show a relation with the water or milk supply, but there was a glaring sanitary deficiency in the shape of privy middens, from some of which, at least, there was soakage into the soil, and the author attributed both the epidemic and the endemic occurrence of typhoid fever in York to the existence of these privy middens. The infection can be carried with ease from these open privy middens by flies and the author thinks that this is a common means of distribution in York. Another serious sanitary defect existed in the sewers, which were laid without sufficient fall, so that the pipes contained many inches of deposit. Although sewer gas may not contain the *bacillus typhosus*, the continued breathing of the foul odors will lower the vitality of the body and tend to break down the natural defences. Reynolds said that Chicago was supplied with water from Lake Michigan by 4 tunnels under the lake, ranging from 2 to 4 miles in length. It had been observed that the mortality from typhoid fever and from acute intestinal disorders followed each pollution of these tunnels. Since the sanitary waterway had been cut through the divide between the St. Lawrence and the Mississippi valleys and the sewage of Chicago had been carried into the Mississippi river, the mortality in Chicago from typhoid fever had been greatly reduced. Groves is of the opinion that the majority of the cases of enteric fever receive the poison of the disease through the medium of the drinking water or of water used in the dilution of milk. He referred to Frankland's experiments which showed that the typhoid bacillus ceased to be infective after 5 days in river water. The toxins present from the large number of microorganisms in river water are supposed to have destroyed the typhoid bacilli. Pakes stated that it was practically impossible to give an opinion concerning the safety of a certain water merely from the enumeration of the microorganisms present. A complete bacteriological examination should be made. On several occasions he had found the *bacillus coli communis* in water that only contained 120 to 150 microorganisms per ccm. However few the microorganisms may be, any sample of water that contains one colon bacillus in 30 ccm. should be condemned. In the differentiation between the typhoid and the colon bacilli he referred to the power that the latter group possessed, that the former group did not, of decomposing salts of formic acid into hydrogen and carbon dioxide. Drysdale thought that sufficient importance had not been attached to the dissemination of typhoid fever by dust. [J. M. S.]

2.—Savage considers the use of neutral red an efficient aid in the detection of the *bacillus coli communis* in drinking water. Ten cc. of the suspected water are added to a tube of ½% glucose neutral red broth and a second tube of neutral red glucose broth is retained as a control. After incubation at 37°C. for from one to three days the red color is changed to yellow or orange if the bacillus coli communis is present. A negative reaction, while not certainly excluding the bacillus coli communis, makes it very improbable that that organism is present. Although other organisms are able to produce the reaction, which is only one of reduction, the error is only about 5%. [J. M. S.]

3.—In the recent arsenical epidemic there can be no doubt that much arsenic was present in the beer and that it was to a great extent unrecognized. Wanklyn believes that the failure to recognize the arsenic is due partly to the abandonment of the real Marsh process in England and partly to the fact that arsenic is protean in its combination. [J. M. S.]

4.—Legge opened a discussion on the **diseases of occupation** in the section of State Medicine. The differences between the symptoms of poisoning in workers in certain poisons and the symptoms produced when the same poisonous substances are taken medicinally are very striking. This is particularly true of potassium cyanide, potassium chromate, arsenic, mercury, phosphorus and lead. The manufacture of potassium cyanide is almost innocuous. One of the most difficult points in relation to occupational diseases is the estimation of the effect of dust on the lungs and the relation of fibroid phthisis, to true phthisis. With the exception of the inhalation of mineral dust containing high percentages of silica, of steel dust, of flax dust and a few others, evidence as to injury of the lungs has not been made very clear. However, the close relation between fibrosis of the lungs and tuberculosis teaches the lesson that attempts to control the former by improved ventilation must be associated with collateral attempts to check the latter by (1) education of the workers as to the infectious nature of the disease and (2) suitable action on the part of the health authorities, particularly concerning splitting. Since 1895, it has been compulsory for practitioners in England to notify the Chief Inspector of Factories of every case of lead, arsenic, mercury or phosphorus poisoning and every case of anthrax contracted in a factory or workshop. The reports resulting from this notification have brought out the interesting fact that, in the male sex, poisoning by lead is especially liable to result in saturnine palsy, while in the female sex, headaches, anemias and encephalopathies are more common. From the statistics obtained from the workers in the china and earthenware industry it has been shown that of the employees who come in contact with lead, women are about twice as susceptible to its noxious influence as men. Notification has been especially useful in obtaining knowledge of hitherto unsuspected sources of mercurial and arsenical poisoning. Anthrax is the most protean in its manifestations of all trade diseases and the most difficult to control. Disinfection of horsehair by steam is difficult on account of the hydraulic pressure used in making up the bales and the grease and dirt of the hair. The accepted treatment of anthrax is the excision of the pustule as soon as it is diagnosed. In the country districts, however, where the practitioners are reluctant to resort to surgery, the application of caustics or the hypodermic injection of pure carbolic acid has been remarkably successful. Alcoholism and the consequences of bad housing conditions are factors that contribute to the severity of trade diseases in many cases. **Chronic brass poisoning** begins by the appearance of an anemia of the ordinary oligemia type, accompanied by malaise, headache and extreme weakness and nervousness. The complexion becomes sallow, the patient becomes thin, his muscles waste and there is a loss of strength with muscular tremors and neuralgic pains. Symptoms of catarrh of the air passages are common. There is a green line at the base of the teeth and skin eruptions are met with which are due either to the action of the brass dust directly on the skin or to the action of the sweat impregnated by copper salts. The disease bears a close relation to consumption. Murray believes that copper is the cause of the disease, and the poison evidently gains entrance to the body through the digestive and respiratory tracts. Pure phosphorus, in doses of 1-30 grain, or phosphoric acid exercise a remarkable influence on the disease. Ellis discussed **glass poisoning**. The glass cutter polishes the glass on which he has already cut a design with putty powder, which contains lead and tin. From the use of this powder cases of lead poisoning arise. Scott adds **railway work** to the list of dangerous occupations. Many of the railroad accidents are due to the neuroses of railway servants and these neuroses are the result of the nervous tension at which the individual is kept while performing his duties. Dearden believes that **phosphorus necrosis** is due to a combination of general and local causes. The poison, acting on the blood, surcharges it and, on account of its affinity for bone, softens those organs and thus the tissue is weakened in its resistance to local injury. The

local injury, in the case of the maxillary bones, is supplied by means of carious teeth. Reid believes that one cause of the high infant mortality in certain factory towns is the fact that mothers go to work in the factories, leaving their children to be fed artificially by incompetent persons, instead of staying at home and nursing their babies. Graves spoke of **plumbism** in carriage workers. [J. M. S.]

5.—The **prevention of the spread of plague** from Bombay is due to the excellent **sanitary administration** of the port. This sanitary system includes systematic medical inspection, disinfection and sanitary control of all passengers, crews and ships prior to their departure from Bombay, combined with the detention of all doubtful or suspicious cases of illness for further observation in the hospitals and segregation camps of the city. The paper includes a description of the measures adopted. Adams is convinced that there is much truth in the rat theory, but he believes that there are many other sources of infection. [J. M. S.]

6.—Dhingra believes that **Hankin's method of disinfecting wells** by pumping them after 2 or 3 ounces of potassium permanganate have been thrown in them is fallacious in theory, defective in technique and impossible of application. [J. M. S.]

1.—Walsham speaks of the comparative benignity of columnar-celled carcinoma of the colon the disease often progressing to complete stenosis of the gut without there being lymphatic involvement or metastases. The diagnosis is therefore of vast importance since if the growth be removed early cure may follow. The following symptoms should direct our attention to a carcinomatous stricture in the early stage: Abdominal uneasiness and distension, often classed as indigestion but not referable to the stomach and not benefited by medical treatment; attacks of pain or spasm referred to the colon, frequently occurring daily without reference to the time of eating; almost always liquid stools; progressive loss of weight; and constant desire to defecate. When seen early the only treatment of course is complete extirpation, removing a wide margin of healthy bowel. When symptoms of acute obstruction are present the operation should be done in two stages, the first stage consisting of a preliminary colotomy, and the second stage, in from ten days to a fortnight later, when the patient has recovered from the deleterious effects of the obstruction, consisting of the wide extirpation already mentioned. These remarks are based on some ten or twelve cases which have come under the author's care during the last few years. [F. T. S.]

2.—Brownlee gives an account of his experience in the treatment of bubonic plague with Yersin's serum which was prepared in the Pasteur Institute of Paris. He remarks that the value of this treatment cannot be properly estimated from the results of this series, as the disease was of a mild character in most of the cases. He reports a number of cases. The first case was of the septicemic variety of plague with multiple bubo. The temperature fell 26 hours after the first administration of ser-

um, and the patient seemed out of danger. The second case was an example of the fulminant type of plague. In this case 20 cc. of serum was injected intravenously and the same amount subcutaneously. All the symptoms abated within 24 hours. The third case was one of mild bubonic plague. 20 cc. of serum were injected subcutaneously into the abdominal wall. On the third day, the symptoms abated somewhat, but it was deemed advisable to again inject the same amount of the remedy into one of the veins of the right arm. This was followed by immediate improvement of the condition of the patient. The fourth case was also an example of mild plague. The patient suffered from a bubo in the left axilla. The serum was injected and improvement in the gravity of the symptoms followed for a short while. The severity of the disease again increased and a dose of 20 cc. of serum was injected intravenously and a rapid recovery followed. The fifth case was another example of rather mild plague. The patient had a bubo in the right inguinal region. Subcutaneous injection of the remedy was not followed by any great improvement in the symptoms, so it was determined to inject 20 cc. intravenously. As in the two preceding cases, improvement followed immediately. The author emphasizes that subcutaneous injection of Yersin's serum produced little effect or only a temporary abatement in the symptoms, while intravenous injection of the remedy was followed by rapid subsidence of the symptoms. He reports four cases in which the serum was used and in which the disease progressed to a fatal issue. In the first case, the disease had lasted four weeks and at the time the remedy was employed there was an extensive secondary pyogenic infection of the buboes. The second case was of interest, as the patient was an extremely ill woman about time the remedy was used. At the height of her illness premature labor was in progress. She apparently received little benefit from the use of the serum and death occurred on the third day of the illness. The serum in this case was injected into a vein of the right arm and also into the subcutaneous tissues of the flexure surface of the left thigh, so that it might drain into the bubo situated in the left groin. 20 cc. were also injected into the loose tissues of the abdomen. The outcome in this instance can in no way appraise the serum treatment because the case was complicated. Post-mortem examination showed that the retroperitoneal glands were the seat of mixed infection. The third fatal case was also an example of a mixed infection. The patient came under observation during the second week of the illness. One of the buboes had progressed to abscess and the only micro-organism found in the pus, was the staphylococcus pyogenes aureus. No effect of any kind followed the administration of the serum. The fourth case in this series was of a very interesting nature. The patient, a girl of six years of age, when she came under observation, was profoundly ill and in a state of almost complete unconsciousness. By puncture, plague bacilli were isolated from a bubo in the right groin. Serum was injected intravenously without apparent effect. 100 cc. were also used subcutaneously. On the fourth day after her admission there was an improvement in her condition, but it was only of the temporary nature, and death occurred on the eighth day, preceded by symptoms of heart failure. In two of the fatal cases, the plague bacilli isolated from the buboes which received the drain of some of the serum, were degenerated markedly, while the micro-organisms from other parts of the body were virulent and did not exhibit this peculiar change. The author directs our attention to the fact that the remedy was used as a prophylactic measure in two patients who afterwards developed a mild form of the disease. He therefore concludes that a dose of 10 cc. of serum while in no way affording protection, probably induces a certain degree of immunity. With regard to its curative action, he points out that this remedy, when injected subcutaneously, has little curative value. He explains this on the ground that the lymphatics exercise a distinct action on the serum whereby the antitoxic substances are retained largely in the glands which drain the area of injection. This also seems to be proven by the fact, as noted in two cases, that the micro-organisms in the glands which received the serum, presented degenerated changes, while the organisms in other parts of the body were not affected. Subcutaneous injection can only benefit those cases in which the infection is localized

to the single bubo. Intravenous injection in most cases has a marked therapeutic effect even when the disease was far advanced. He remarks that it is reasonable to assume that the doses which he employed in some of his cases were too small and that should an opportunity to use this remedy again present itself, he would employ an initial dose of 60 cc. or more intravenously, and that the subcutaneous injection would probably only be practiced in the areas draining into infected lymphatic glands. [F. J. K.]

3.—Curtis reports a case of primary hemorrhagic otitis media, which occurred in a female aged 35 years, without any immediate previous illness. The patient, on November 13, 1900, at 8 P. M., which was two hours before retiring, complained of noises which were referred to the back of the head on both sides of the middle line on about the level of the lambdoid suture. Very soon, the noises ceased and excruciating pain developed in the occipital region, just where the noises had been. The severity of the pain increased. At 2 P. M. she experienced the feeling of something bursting inside the head at a point located just to the left of the occiput, and about this time, she also noticed a flow of bright red blood which soon became darker, from the left ear. The bleeding decreased gradually. At 11 A. M., only a few drops of the pale serum escaped. The acute pain subsided with the appearance of the hemorrhage. For two days, the treatment consisted of syringing the ear with warm boric acid solution. Some time after, the patient complained occasionally of dizziness. On November 29, the examination of the left ear, showed that there was a large perforation of the membrana tympani. The hearing was very good. There was a small clot occluding the perforation in the ear drum. On December 6, the patient complained of singing or frying noises in the left ear and occipital headache. A blood clot was found lining the inner wall of the tympani. The pain and headache soon disappeared. Four attacks of a similar nature occurred during the winter and on February 27, 1901, she was reported as being perfectly well. The author states that this case was probably an example of primary hemorrhagic otitis media. [F. J. K.]

4.—Klein and Williams give an account of some experiments with the Danysz Bacillus. Danysz has suggested that this bacillus is capable of producing an acute, fatal, septicemic disease in rats, and that the dead animals would probably constitute a focus for further infection—the disease rapidly spreading and exterminating these animals or causing them to migrate from their locality. As the rat has been instrumental in spreading Bubonic plague, these facts were thought to be important in preventing the spread and communication of plague to the human subject. In the investigations of Klein and Williams, they demonstrate that the Danysz bacillus showed a high degree of virulence in their laboratory experiments, but with practical tests in a dock ware-house in the port of London, the results were far from satisfactory. They placed a rat, which had died after a subcutaneous injection of septicemic disease, in the warehouse. This animal was not touched by the rats. They also offered dead mice and guinea pigs, which were readily eaten by the rats of the warehouse. The results were entirely negative. They observed that rats kept in captivity were liable to succumb spontaneously. This was found to be the case in 25% of the animals, within the first ten days. Therefore they state that this fact should be borne in mind when experiments are performed in the laboratory, and only such animals should be experimented upon which survive after the first week or fortnight of captivity. [F. J. K.]

5.—Ashby gives an account of a case of so-called fetal or congenital rickets. The mother of the infant in question was 48 years of age and had had 14 children. Two of these had died in infancy from some wasting disease. There was no history of syphilis; her only complaint being an attack of jaundice, which occurred before and after the birth of the infant suffering from rickets. At birth, this infant was well nourished. When two weeks old, he was admitted to the Manchester Children's Hospital, suffering from fractures involving the right humerus and radius and the left humerus, ulna, and femur. There was no history of violence of any kind. Craniotabes was present, which involved the occipital and parietal bones. The ribs were soft and bent inward during inspiration, producing broad shallow grooves on each side of the sternum. There were no enlargements at the end of the long bones or any curvatures. The infant was fed on cow's milk and water. When six

weeks old, the right femur was fractured. All of the fractured bones repaired well. At the age of nine months, the infant presented no signs of rickets or infirmities of the bones. [F. J. K.]

6.—Thornton details the history of a woman, aged 27 years, who came under his care about the twelfth day of an attack of **typhoid fever**. Fifteen days after the temperature had become normal a definite relapse developed and on the eighteenth day of this relapse intestinal perforation occurred. Symptoms pointing to perforation were pain, colicky in character, and felt in the right lower quadrant of the abdomen; a rise of temperature of three degrees; a quickening pulse; thoracic respiration; disappearance of liver dullness. The abdomen was scaphoid. He asserts that in these cases a rise of temperature is frequently seen, the fall of collapse not occurring until some hours later; that perforation may occur with a scaphoid abdomen, distension following the consecutive peritonitis; that abolition of liver dullness without tympanites is almost conclusive proof of perforation, that even if there be tympanites the liver dullness is never absent in the mid and posterior axillary lines without perforation having occurred; and that in perforation the pulse and respiration are usually markedly increased in rate. In the case reported a "cracked pot" sound was obtained over the eighth intercostal space in the mid-axillary line. The patient was operated upon by Mr. Godwin, under local anesthesia. There was no peritonitis. The ulcer that had perforated was about three inches from the ileo-cecal valve. The operation was performed 2 hours after the onset of symptoms. The patient died 8 days after operation, not from the operation or from the perforation, but from the effects of the fever, as the postmortem demonstrated. [F. T. S.]

7.—Ravenel communicated a very important paper to the British Congress on Tuberculosis on the comparative virulence of the tubercle bacillus from man and bovine sources. A correct idea of the scope and nature of these interesting and important experimental investigations can be formed only by reading the original article. From the evidence which Ravenel has quoted, he draws the following conclusions: (1) In culture, the tubercle bacillus from bovine sources has fairly constant and persistent peculiarities of growth and morphology; sufficient to identify it from the bacillus found in man. (2) The pathogenic power of the cultures from two sources differs so markedly as to afford further means of differentiation. The bovine bacillus was found very much more active for all species of animals which he tested, with the possible exception of swine, which are highly susceptible to both the human and bovine bacillus. (3) He found that the comparative pathogenic power of the tuberculous material from cattle and from man corresponds closely with pure cultures of the tubercle bacillus from the two sources. (4) "That it is a fair assumption from the evidence at hand, and in the absence of the evidence to the contrary, that the bovine tubercle bacillus has a high degree of pathogenic power for man also, which is especially manifest in the early years of life." [F. J. K.]

8.—Tyrle gives a report of four cases of atypical empyema which were observed in general practice. He directs our attention to the frequent difficulty in making a diagnosis of this condition and the uncertainty of the prognosis in many cases. Sometimes when we least expect a favorable termination, the patient recovers, and at times when we are confident of a happy result, the ending is disastrous. [F. J. K.]

9.—Prowse suggests "an improved method of photographing pathological specimens." He accomplishes this by submerging the specimen in water and by placing the camera in a vertical position. The water should be perfectly clear. Under the glass jar containing the water, a piece of white blotting paper or a dark piece of wood should be placed; this forms an excellent background. [F. J. K.]

HOWARD BLIENTHAL.

5. Remarks on the Scientist, the Practitioner, and the Antitoxin Treatment of Diphtheria.

ADOLPH RUPP.

1.—Charles Stedman Bull discusses **metastatic chorioiditis occurring in the course of pneumonia due to grippe**, based on a study of six cases with two autopsies. Metastatic ophthalmia was first observed in cases of puerperal fever. It was subsequently met with in other forms of septic fever, and was described as **phlebitic ophthalmia**. It has been assumed that the occurrence of metastatic ophthalmitis signifies that the general disease has taken on a particularly severe type, but that it is doubtful, for if true, the ocular metastases would of necessity be regarded as of peculiar and unusual importance, and would have a marked prognostic significance. The frequent bilateral appearance of metastatic chorioiditis, like all bilateral ocular lesions, must be regarded as symptoms of a general constitutional condition, and in such cases we should expect to find numerous metastases in other parts of the region of distribution of the carotid arteries. The disease, as presented in the six cases which form the basis of this paper, was characterized by pain in the eye and head, intense vascular congestion, with the usual symptoms of irido-chorioiditis, and rapid and total loss of sight. The condition may be ushered in by severe headache and vomiting, rise of temperature, and general febrile symptoms. Intra-ocular tension is at first increased, but subsequently sinks much below normal, even when no perforation of the eyeball occurs. The course of the disease is from three to six weeks, and the prognosis is always bad, the case ending in total blindness and shrunken eyeball. The writer does not believe enucleation of the eye is advisable in the acute stage of suppuration, especially if the capsule of Tenon or the orbital tissue be involved. [T. L. C.]

2.—M. P. Overholzer discusses **protozoal life in the blood of man and animals, and some of its evolutionary phases in the bodies of suctorial insects**. One of the most interesting and valuable discoveries of recent date, is the discovery and positive demonstration of two distinct life cycles of some varieties of sporozoal micro-organisms, and the study of the evolutionary phases of these parasites in the intracorporeal and extracorporeal cycles of their existence. This study has thrown much light on those diseases for which the sporozoa are responsible. The author gives a number of interesting examples of the development of some varieties of the sporozoa, including the great scourge of the silk worm, called **pebrine**, which was found by Cornelia to be due to protozoal oval parasitic bodies in the tissues of the developed silk worm. He also describes the development of our knowledge of **bactrachian** or **reptilian** as well as **avian malaria**. He lays especial stress on the accepted value of routine microscopical examination of the blood in all cases of suspected malaria. [T. L. C.]

3.—Charles Gilmore Kerley furnishes **suggestions on infant feeding**. He believes that the most usual error is in beginning at birth with too strong a milk mixture, and inattention to the needs of each case. The milk used for an infant's food should be handled as little as possible. He prefers that milk and cream should not be subjected to the centrifugal process. For the preparation of food two bottles of the best milk and cream should not be subjected to the centrifugal process. For the preparation of food two bottles of the best milk obtainable are required daily. From the top of one bottle all the cream is removed. This is for the reason that that nearest the top of the bottle is much richer in fat than that which joins the milk. The remaining bottles supplies the milk. This should be thoroughly mixed before opening. One pint is used as a basis of measure for our calculation. Tables are given showing the percentage of fat, protoid and sugar in certain convenient mixtures of cream and milk and water. Pasteurization and sterilization are mentioned, and the author states that while milk is rendered more indigestible by heating, it is safer for use. Certain children are unable to digest cow's milk in sufficient quantities, so that two measures are left, the **peptonizing of milk** and the **use of cereals**. Pep-

tonizing is without value except in those cases in which completely peptonized milk is introduced into the stomach by gavage, or into the rectum. He does not believe that this process is of special value. As to cereals, he has found them useful in a treatment of barley water, two tablespoonfuls of barley to the pint, 7% of fat, 3 of proteid and 2 of soluble carbohydrates. If we are to feed cows milk to many delicate infants, we must first remove the casein, which is accomplished by the use of rennet or pepsin, and moderate heat. He mentions many difficult points of feeding and the rare condition of milk idiosyncrasy. [T. L. C.]

4.—Howard Lillenthal presents a paper on the clinical aspects of acute intestinal obstruction. The causes which contribute most to the mortality of this affection are: First, the shock incident to the strangulation of a vital organ. Secondly, sepsis from within the distended and congested gut, even without the onset of peritonitis, and third, the embarrassment of the functions of the lungs and heart by the distension itself, with subsequent exhaustion of the vital forces in an already weakened individual. Either of the two first cases may be fatal without the existence of the third. He believes that true ileus is often due to appendicitis. He does not refer to the banus left over from the previous attacks, but to the co-existence of both acute conditions. Tight strangulation in the small intestine occurring suddenly is accompanied by intense colicky pains, with nausea and vomiting, the ejection of the stomach contents often being violent. Collapse comes on early. Hiccough and frequent strangulation without nausea are common in the later stages of ileus and should be regarded as particularly ominous. The medical treatment of intestinal obstruction of the acute kind is safe until the diagnosis is made, but no longer. He reviews some of interesting recoveries following the employment of atropine. Surgery and surgery alone, can promise relief in acute intestinal obstruction. The fear of operation must answer for many an opportunity missed, and many a life lost. When a patient has recovered after internal medication, or massage and electricity, it is certainly illogical to conclude that an operation would have had a less fortunate result. [T. L. C.]

5.—Adolph Rupp presents some remarks on the scientist, the practitioner, and the antitoxin treatment of diphtheria. This author believes that antitoxin and the philosophy of the scientists in its favor as applied to the treatment of diphtheria in human beings is practically a rapidly vanishing possibility. As reason for this statement it has been generally admitted that the diphtheria antitoxin antagonizes only the diphtheria toxin, and that the amount of toxin in a person suffering from diphtheria is an unknown quantity. He also avers that it is now almost generally admitted that the phenomena of diphtheria in the clinical sense are induced by bacteria and their toxins other than the Klebs-Loeffler bacillus, and says also that it is demonstrated that many cases of clinical diphtheria are not specifically Klebs-Loeffler in character, and that a great many Klebs-Loeffler diphtherias are barren of all clinical evidences of diphtheria. Therefore, concludes this writer, antitoxin is practically a remedy of very limited utility. [T. L. C.]

MEDICAL NEWS.

August 31, 1901.

1. Blood Examinations as an Aid to Surgical Diagnosis. JOSEPH C. BLOODGOOD.
2. The Racial Factor in Hysteria. JULIUS ULLMAN.
3. The Drug Habit; Its Cause and Restriction. JOSEPH M. AIKEN.
4. Two Fatal Cases in Infants. Pemphigus and Erysipelas. FRANK S. MEARA.

1.—J. C. Bloodgood in his article on Blood Examination as an Aid to Surgical Diagnosis gives the following interesting facts: Although there are exceptions to the rule, a rising leukocytosis is an indication for an operation. In the majority of instances, if the leukocytes reach 18,000 before forty-eight hours, it has been an indication of an advanced pathological lesion. For example, excessive exudate with a diffuse appendicitis, gangrene, or an appendix distended with pus, abscess, or beginning peritonitis. When the leukocytes have been below 18,000, or, when counted a number of times, have fallen in number, the pa-

tients have recovered without operation. With a fall in the leukocytes there has been associated a rapid cessation of the local symptoms, or, if operated on, the appendix has been the seat of but slight diffuse inflammation. Observed later in the attack, especially after the fourth day, a high leukocytosis has usually been associated with the localized abscess, or beginning peritonitis. It is to be remembered, however, that it is possible to have an abscess with a low leukocyte-count. Out of the fifty-six cases of appendicitis with abscess fourteen have had a leukocyte-count between 6,000 and 12,000; the remainder have been higher, the majority over 20,000; the usual count is between 20,000 and 25,000, one count 30,000, one 60,000. It is also to be remembered that with peritonitis there may be a very low leukocyte-count. This, so far in our observations, has been associated with an extreme septic condition of the patient, and in every case death has followed. These low leukocyte-counts have been observed in patients admitted to the hospital three days or longer after the beginning of the attack, so it is difficult to ascertain the exact duration of the peritonitis. Observations are sufficient to indicate that in the majority of instances beginning peritonitis is associated with the rise in the leukocytes, which, however, falls as the patient becomes more septic. In a general way we may feel that a patient admitted with symptoms of peritonitis, with a high leukocyte-count, has a better chance for recovery. The leukocyte-count simply indicates, however, a short duration of the peritonitis. The positive prognosis depends more upon the bacteriological findings than upon the leukocytosis. The author also emphasizes the following: A rapid rise in the leukocytes, especially above 18,000, should, in his opinion, be a sufficient indication for exploration, even in those cases in which the local symptoms are very slight. In a few exceptions in which the local symptoms are sufficiently distinct to indicate an operation a low leukocytosis should not influence as to delay operation. [T. M. T.]

2.—J. Ullman gives certain etiologic factors, classified by Gilles de la Tourette, which, if allowed to play a role, will overwhelm the individual and will cause definite symptoms of hysteria to appear in any race, be it Caucasian, Mongolian, American, Ethiopian or Malayan (1) Influences of the emotions, including moral passions, such as disappointment, anger; influences of education, a higher civilization being conducive to the disease; religion with its furors and frenzies; (2) Traumatism, physical and mental; the traumatic neuroses of the Germans; (3) General diseases, typhoid, pneumonia, scarlatina, tuberculosis, grip, rheumatism, diabetes, mellitus, malaria, syphilis and chlorosis; (4) Influence of the sexual organs; as the term implies, the uterus was supposed to be the seat, but, as Chareot later showed, the ovaries seem to be a factor also; (5) Influence of intoxications, lead, alcohol, mercury, sulphur, carbon, and tobacco, the effects of chloroform, ether, morphin, and lastly ptomaines. [T. M. T.]

THE NEW YORK MEDICAL JOURNAL.

August 31, 1901.

1. The Diagnosis, Etiology, Prophylaxis, and Treatment of Cystitis, Pyelitis, and Pyelonephritis in Women. THOMAS R. BROWN.
2. A Study of the Temperature, Pulse, and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain. J. T. ESKRIDGE.
3. The Esophagometer, or Intragastric Whistle. A New Device for Measuring the Length of the Esophagus in the Living. C. D. SPIVAK.
4. Dupuytren's Contraction of the Palma Facia. NOBLE SMITH.
5. The Effect of Nasal Stenosis on the Throat, Ear, and Organs at a Distance. W. PEYRE PORCHER.
6. Atrophic Rhinitis in its Purely Clinical Aspect. CARL SEILER.

1.—T. R. Brown concludes as follows: (1) The great majority of cases of pyelitis, pyelonephritis, and cystitis are due to infection with various micro-organisms (of which the colon bacillus is the commonest) which may reach the kidney or bladder either exogenously or endogenously. (2) That in the majority of cases the condition can either be prevented or can be cured if the conditions underlying its development are recognized and un-

derstood, and the correct measures inaugurated. (3) There are various conditions, such as urinary hyperacidity, which may simulate almost exactly true vesical infections, and yet in which misinterpretation and improper treatment may lead to the development of true cystitis and its deplorable consequences. (4) In no condition is prophylaxis more essential than in that of the infections of the urinary tract, while, to be able to prevent such conditions, we must have constantly before us the danger of the development of infection in all cases associated with conditions which tend to lower the general resistance of the patient, and also those which render the bladder susceptible to infection, especially by the trauma of an operation or catheterism. (5) While an absolute diagnosis of renal infection can be made only by ureteral catheterism, in the majority of cases a very probable diagnosis may be arrived at by a consideration of the relation between the grade of albuminuria and pyuria and by careful cystoscopic examination of the bladder, especially that portion about the ureteral orifices, and the character of the urine flowing therefrom. (6) Contrary to the opinion expressed in the majority of text-books, a great majority of the infections, both of the bladder and of the kidney, are associated with acidity of the urine—that is, are due to micro-organisms which do not split up the urea. (7) Probably in the majority, if not in all the cases of renal infection due to a urea-decomposing micro-organism, after the condition has lasted for a certain length of time, a stone is formed by the decomposition of the precipitated salts about the bacteria as a nucleus. (8) And, finally, to be able to thoroughly understand the cases of cystitis, pyelitis, and pyelonephritis brought to our notice, to make the proper diagnosis, to inaugurate and carry out a rational line of treatment, to be conversant with the proper means of prophylaxis, and to give a correct prognosis, a careful chemical, microscopic, and bacteriological study of the urine is absolutely essential. [T. M. T.]

2.—J. T. Eskridge gives in his article on "The Study of the Temperature, Pulse and Respiration in the Diagnosis and Prognosis of Certain Critical Diseases of the Brain" the following facts. (1) In all critical brain cases the temperature should be registered every two or three hours, and in some cases every hour, both day and night. It is best taken by the thermometer in the mouth, but as this can only be done when the patient is conscious, it will often be found necessary to use the rectum or axilla. The author prefers the three to five minute thermometer to the one minute one, on account of the latter's susceptibility of very slight variations of temperature. With either instrument it should be left in place at least one minute after the mercury has ceased to rise. In taking the temperature in the axilla the following should be borne in mind: In all cases in which the axillary temperature is to be taken, the author directs the nurse to dry the axilla with a cloth, cover the patient to the neck, and see that the arm on the side corresponding to the axilla in which the temperature is to be taken is kept lying across the chest for a period of, at least, five minutes before the thermometer is put in place. The thermometer is held by the nurse with the bulb against the upper portion of the axilla, while the upper arm is held firmly against the chest. The thermometer is held in place one minute after the mercury ceases to rise. In cases of hemiplegia, in which bilateral axillary temperatures for some reason are not taken, the nurse should alternate between the right and left axilla in taking the temperature each time. It is very important to register the temperature in each axilla in certain acute unilateral brain diseases. The pulse also bears an important part in diagnosis. In a child whose pulse is 120 and regular in character and a temperature of 101° or 105° would indicate that the disease was not organic trouble of the brain, unless there were some localizing brain symptoms, such as are sometimes found in meningeal hemorrhage. A pulse of 100 to 120 and temperature of 102° would be consistent with a tentative diagnosis of tubercular meningitis being probable. If other symptoms pointed to such a condition. An extremely rapid pulse of 120 to 140, with a temperature of 105° would almost enable one to exclude meningitis and suspect scarlet fever. A pulse of 100 to 120, a temperature of 101° or 105°, and respiration 30 to 40 a minute would indicate pulmonary instead of brain trouble. An uncomplicated acute meningeal inflammation is usually ushered in with a pulse from 90

to 120 and a temperature of from 102° to 103°. In persons with apoplexy, with or without hemiplegia, if the pulse is rapid, the greater the probability that the apoplectic attack is due to a thrombus or embolus, and not to hemorrhage. A slow pulse of 60 to 80 is the rule in the exudative stage of acute meningitis. A pulse of from 40 to 60, especially if irregular and intermittent, as it usually is, denotes great cerebral disturbance and rapid progress of the disease. The slower the pulse in apoplexy, the greater the probability that the stroke is due to hemorrhage. The typical pulse of abscess of the brain is slow until that stage is reached in which the functional activity of the brain is greatly impaired. In traumatism of the brain a slow pulse denotes in the majority of instances either hemorrhage or a depressed fracture, and, if the pulse is irregular or intermittent, that the respiratory and cardiac centres are affected. [T. M. T.]

3.—C. D. Spivak describes his **esophagometer** or **intra-gastric whistle** as follows: It consists of a stomach tube provided at its proximal end with a whistle. The whistle is inserted in such a way that its opening, through which the air is blown in, looks toward the distal end, and the opening through which the air makes its exit is in apposition with the side opening of the tube. The whistle is secured in the tube by tying it externally with a piece of catgut or silk. The tube is introduced into the esophagus, and the air blown in by means of a pump, Davidson syringe, Politzer bag, the mouth, or what not. So long as the whistle traverses the esophagus the instrument is smothered and no sound is heard. The tube can be pushed forward and backward several times so as to ascertain the exact point at which the whistle becomes audible. The distances between the distal border of the side opening of the tube and the point at the incisor teeth where the whistling sound is first heard represents with precision the distance between the incisor teeth and the cardia. The esophagometer is to be used in patients who have swallowed the stomach tube several times, and whose stomach is empty. The advantages of this device are: (1) Precision in measurement not attainable by any of the other methods, except by that of Purjesz. (2) Cheapness. The materials necessary for manufacturing this instrument are (a) a stomach tube, (b) a whistle, and (c) a piece of thread. It does not take more than two minutes to insert and secure the whistle in the tube. (3) No special instrument is needed. It is an esophagometer only when used for the purpose of esophagometry. In the twinkling of an eye the component parts are separated and we have our stomach tube and whistle ready for other uses. [T. M. T.]

5.—W. P. Porcher states in his article that it is well known that a complete nasal occlusion from inflammation or obstruction will often set up an otitis which may have a disastrous effect upon the ear, but it is rarely recognized that a small growth occupying the olfactory rather than the respiratory nostril may result in equally serious consequences, even to partial or complete deafness, severe and prolonged coughs, etc. It is therefore necessary in our surgical procedures in the nose that extreme care be used lest serious and unexpected intercurrent disease be set up in the adjacent organs. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

August 29, 1901.

1. The Treatment of Stricture of the Esophagus. THEODORE DUNHAM.
2. A Discussion of the Indications for Operation in Gastric Ulcer. ARTHUR T. CABOT.
3. Cancer of the Intestine. FRED. H. LUND.
4. New Procedures in the Treatment of Hip Disease; Operative Dislocation and Drainage of the Acetabulum in Acetabular Disease. E. H. BRADFORD.

1.—Dunham describes an instrument which he uses for dilating stricture of the esophagus. A black thread is washed down the esophagus into the stomach and the end fished out through a gastrotomy opening. Wire-and-splide bougies are then attached to the stomach end of the thread and pulled through the stricture. [J. M. S.]

2.—Cabot believes that with gastroenterostomy added to the operative repertoire, the surgeon may feel that if he does not find a gastric ulcer accessible to safe removal, or even if he cannot find it at all, he may still be able to

afford relief to his patient by an easy and comparatively safe method. The conditions most evidently demanding interference are: (1) symptoms of perforation, (2) dangerous or persistent hemorrhage, and (3) the occurrence of symptoms that point to chronic course of the ulcer. In case of **gastric ulcer** in which acuteness of pain and tenderness indicate that the ulcer is approaching the peritoneum, it is well to make preparations that will insure a quick operation if the need arises. The danger of fatal hemorrhage is greater in later life, especially where the symptoms point to the existence of a chronic ulcer. Under such circumstances, a tendency to a slight recurring hemorrhage should act as a warning that the ulcer is progressing in a dangerous direction. Gastroenterostomy is efficacious in arresting hemorrhage in a large proportion of cases. The mortality from gastroenterostomy, according to Mikulicz, is 16.2%, while the mortality from the disease is from 25% to 30%. The following summary of the **indications for surgical interference in gastric ulcer** is made by the author: (1) Acute hemorrhages should rarely be treated by operation. When, however, hemorrhage frequently repeats itself, even if severe in amount, it will demand operative treatment as soon as its recurrent character is plain. (2) Small, frequent hemorrhages, threatening anemia, clearly indicate operation. (3) Perforation of the stomach, either acute, with general peritonitis, or chronic, with surrounding adhesions and perigastritis demands instant operation. (4) When an ulcer runs a chronic course with a strong tendency to recurrence, so that the patient's capacity for work and for the enjoyment of life is diminished, an operation is indicated.

[J. M. S.]

3.—The history of the majority of the patients who are subjects of **carcinoma of the intestine** is most unsatisfactory. The surgeon is asked to give surgical aid to patients suffering from the serious emergencies in which this disease terminates, such as general peritonitis from perforation, paraintestinal abscess or complete occlusion of the bowels. These conditions admit, as a rule, of nothing more than palliative operation. Lund believes that the symptoms of emaciation, increasing constipation, perhaps alternating with diarrhea, with localized gurgling of gas and intestinal discomfort, in a patient past middle age, ought to indicate exploratory celiotomy whether a tumor is felt or not. In the rare cases in which a tumor is so situated that it can be felt early in the disease, there ought to be no question regarding immediate celiotomy. As far as we know, the only possible cure of an intestinal carcinoma consists in its early removal and even palliative measures, such as intestinal anastomosis or colostomy, are much more safely performed in the absence of the grave emergency of obstruction and before the patient has been too greatly weakened by the advance of the disease. Absolute localization to a limited portion of the intestine without extensive glandular involvement in a patient in good condition is requisite for successful treatment of an intestinal carcinoma. These conditions demand not only early diagnosis, but frequently exploratory operation in the absence of an exact diagnosis. The author then discusses the different situations in which carcinoma of the intestine is met with. The differential diagnosis is to be made between sarcoma, tuberculosis, benign tumors, carcinoma or tumors of the other organs, fecal impaction, benign scars and tuberculous stricture. He adopts the classification of Boas. (1) Cases in which the subjective symptoms are so clear that no objective signs are necessary. (2) Cases in which the symptoms are doubtful and in which objective symptoms are necessary for diagnosis. (3) Cases in which local symptoms are entirely wanting until the disease has made extensive progress. (4) Cases in which sudden obstruction occurs without previous notable symptoms. Operation is absolutely indicated in all cases in which a tumor is suspected of being carcinoma of the intestine. Operation is indicated in cases in which the symptoms point to stenosis of the bowels, whether a tumor is palpable or not. Exploratory operation is indicated whenever vague intestinal symptoms, associated with loss of weight, in persons past middle age, lead to the suspicion of intestinal carcinoma. In cases in which metastasis has occurred to the peritoneum, the liver, or other organs, no radical operation can be proposed, but all operative measures must be palliative. Excision of the growth with

immediate union of the ends of the bowel is the ideal operation to be sought. Intestinal anastomosis and enterostomy are merely palliative measures. [J. M. S.]

4.—Bradford reports a case of **hip-joint disease**, in a boy, aged 6 years, in which the disease was confined to the acetabulum. The head of the femur was thrown out of the joint by an operation a free incision was made and the acetabulum which was perforated was drained.

- 2.—Maher reports the case of a baby born without some of its fingers and toes. An examination of the baby 15 hours after birth revealed constricting bands of what appeared to be dry fibrin encircling the fingers and toes. After the constrictions had been removed some of the members in the course of time fell off, having been strangulated to such an extent that they could not recover. He believes the trouble in this case arose from the abnormal presence of fibrin in the liquor amni. He takes issue with the majority of writers who leave us to infer that these **amniotic bands** are all outgrowths of the inner surface of the amnion. [W. A. N. D.]
- 3.—Wathen does not believe it is possible for an **ectopic pregnancy** to develop primarily in the peritoneal cavity, for the ovum cannot be lodged securely in any one place sufficiently long to form chorionic attachments, and the peritoneal secretions will very soon destroy its vitality. Ectopic pregnancy must be primarily tubal, tubo-ovarian, or ovarian, but as it cannot develop to term in any of these structures, it ruptures into the folds of the broad ligament or into the peritoneal cavity; and if the chorionic attachments are not then destroyed there is no reason why the pregnancy may not continue to term. He believes that most cases reported as intraperitoneal pregnancy are extraperitoneal, having developed in the folds of the broad ligament or having separated the peritoneum from its attachment, either extending upward posteriorly or anteriorly between the peritoneum and the abdominal wall. He reports a case of what he believes to be an ovarian pregnancy. [W. A. N. D.]
- 4.—Marcy gives an interesting review of the history of gynecology, which he claims is very naturally in origin a subdivision of obstetrics rather than of surgery. He gives a short review of the different pioneers in this line of surgery, together with an account of the slow growth of ovariectomy up to 15 or 20 years ago. He summarizes the contribution of gynecology to surgery as primarily the entire domain of pelvic, abdominal and intestinal surgery. He says that gynecology which only a quarter of a century ago was looked upon with disfavor by surgeons, who stigmatized it as the "art of puttering," has become the chief corner stone in the new edifice dedicated to surgery.

[W. A. N. D.]

5.—Foster reports a case of leprosy. The patient was 20 years of age and had never resided outside of the state of Minnesota. One of his brothers died of leprosy in May, 1898, from which he had been suffering for eight years. The other members of his family, namely, his father, mother, two sisters, and one brother, are in good health. The patient's brother, who died of this disease, had been nursed by a woman who had two brothers suffering from leprosy. The type of leprosy in the case reported by Foster, was of the anesthetic variety; the eruption was scattered in different parts of the body. There was a distinct node on the right wrist, thickening of both ulna nerves, with a number of anesthetic areas in many parts of the body. The author mentions that this case is of interest as the patient was born in Minnesota, and had never been outside of the State. The author also reports a case of multiple *nævus pigmentosus* which occurred in a male 21 years of age. The patient was born in Sweden. The condition had existed since birth, and from that time has grown considerably larger. The lesion was situated principally upon the back. A microscopical examination of the growth confirms the diagnosis. The author also presented a case of suspected *lupus vulgaris* for diagnosis. The patient, 27 years of age, had been suffering from large ulcers and sores over his body for the past 24 years. The extent of the ulceration varied. When the patient came under observation there was an ulcer on the wrist, and about this area there were three jelly-like nodules which resembled *lupus vulgaris*. Nine years ago, the patient was treated with tuberculin which had a favorable influence. The eruption disappeared entirely for six weeks. The author is inclined to believe that this case is one of *lupus vulgaris* and *lupus erythematosus*, combined. [F. J. K.]

6.—Schmidt gives an account of a case of *epidermolysis bullosa hereditaria*. On April 15, 1899, the patient, Edwin B., aged 9 years, presented himself for examination. There was nothing of importance in the family history which pertained to the patient's present condition. He had measles and whooping-cough some years ago. At birth no eruption of the skin was noticed, at the end of the second week, blisters about the size of a split pea, appeared on the soles of the feet just around the heels. Some time after, when the child was three months old, small irregular blisters, varying in size from a pin-head to the size of a lima bean, appeared on the dorsal surface of the hands and fingers. When the child began to walk bullae showed themselves around the anterior surface of the knee, the ankles and the elbows. Many of the blisters ruptured shortly after their appearance, the remaining contents drying in several days. The fluid from the blisters was usually clear, rarely turbid light yellow in color and slightly tenacious. During the last four years of the illness, the contents of the bullae were occasionally blueish purple in color. Repeated acute attacks of adenitis occurred during the last two years of the disease. This inflammation of the lymphatic glands occurred when the bullae became infected. A hemic murmur was heard occasionally over the base of the heart. The child was peculiar in regard to his diet, refusing to take almost all vegetables and fruits. The treatment consisted in the administration of tonics, especially iron, and more recently the patient had been taking cod-liver oil. If the blisters were very large, they were opened and treated antiseptically, as a rule, however, they were not opened. [F. J. K.]

7.—Walls discusses protracted influenzal pneumonia in infancy, and reports four cases of this condition. We are reminded that influenza in infancy is as protean a disease in all its characteristics as during other periods of life. In regard to the etiology, he states that the four infants were fed exclusively on artificial food at the time they contracted influenza. The onset of the disease in these cases of grippe pneumonia was marked with a gastro-intestinal infection, and in a few days by symptoms relating to the respiratory tract. Disinclination to take food was usually the first symptom observed, and if the food was taken vomiting followed. The infants were cross and fretful, and had a high fever; the respirations were hurried and jerky. The cough which was at first slight increased in severity as the disease progressed. The tongue was dry or coated with a moist whitish fur. The bowels were constipated and there was considerable gaseous distension of the stomach and intestines. The temperature curve appeared irregular and intermittent; hyperpyrexia was observed several times. The respiratory rate varied

from 40 to 80 per minute. Very little sputum was raised by coughing. This sputum was not rusty or even blood tinged, it consisted of tenacious glairy mucus. Influenza bacilli were isolated from the sputum of all of the cases. Clinically, the pneumonia was lobar. Consolidation developed slowly, and the typical signs of pneumonia were noted after several days, a week, or even longer. The rate of the pulse varied from 140 to 180. Few nervous symptoms showed themselves in any of the cases. He then discusses the diagnosis, prognosis, and treatment.

[F. J. K.]

8.—Douglas gives an account of membranous colitis. He states that this disease occurs most frequently between the ages of six months and two years. It is usually a disease of marked severity, and endangers the health and life of the child. Its onset is commonly marked by vomiting, high fever, loss of appetite, pain, and frequent large stools of a mucous character. As the disease progresses, the vomiting ceases and the temperature falls. When this does not occur, marked prostration develops. Abdominal pain and distension are constant symptoms. When the irritation involves the lower portion of the colon tenesmus often occurs. The mucous membrane of the bowel not infrequently protrudes, revealing intense congestion of the mucous surface, and often patches of pseudo-membrane. The latter fact is sufficient to establish a diagnosis. Blood is quite constantly found in the stools, but it should be borne in mind that the appearance of the pseudo-membrane is the only feature which positively establishes a diagnosis. This false membrane does not often appear in large amounts, while mucus and blood are more constantly present and continue to appear for a considerable time. The amount of mucus and the length of time it continues to pass, are of value in determining the severity of the attack. The disease generally runs a course of from ten days to two weeks, and when of longer duration, the prognosis is unfavorable. The author mentions that when the disease occurs in young infants under six months of age, it is generally because they are improperly fed. He gives a report of three cases. [F. J. K.]

9.—Keen's patient was a boy aged 10 years. He suffered his first paroxysm of pain when 2 years old. The skiagraph showed a *ureteral calculus* one half the size of the last joint of the little finger in the left ureter, which was thought to be at the pelvic brim, but which was found a little below this level at operation. An oblique incision was made above and parallel with Poupert's ligament, and the peritoneum pushed back. Considerable difficulty was encountered in isolating the ureter. A hard mass in which the ureter was apparently lost, was found just above the bladder. This was incised and the stone removed. It had evidently ulcerated through the posterior wall of the ureter and lay in a sac partly intra- and partly extra-ureteral. The incision in the ureter was closed by a continuous catgut suture, and a gauze drain was placed against it. Recovery was uneventful, no leakage taking place. [F. T. S.]

10.—McCosh says the reasons for rapid relief in cases of pressure on the cord are as urgent as those of pressure on the brain, though the operation for fractured vertebrae is less satisfactory than trephining for fractured skull. The reverse may be said to be true in regard to tumor. As reasons for delay may be mentioned great shock, and uncertain diagnosis. In the cases where operation is not indicated the symptoms are prone to be irregular. Paralysis are not complete and often muscles of the same group may not be equally affected. The anesthesia is only partial and paresthesia with patches of hyperesthesia is common. Symptoms of irritation are apt to be less pronounced. On the other hand when there is definite pressure on the cord the parts are apt to be decidedly affected. Reflexes are apt to be abolished. If at the end of 12 or 24 hours the condition seems questionable, it is wise to explore, the danger being slight. In a certain class of cases, cord injury is followed by early and persistent improvement up to a certain point, when it ceases and degenerative changes develop. In such patients the symptoms may be due to hemorrhage, inflammatory extravasation or to pressure by fragments of bone. The former disappears gradually but the latter can only be removed by operation. It is often impossible to determine which one of these causes is responsible for the symptoms, but as long as improvement continues it is wise to wait, unless it be positive that a fragment of bone presses on the cord. Ten cases are reported to fortify the assertions made in this paper. In 159

cases collected by Lloyd there were 59 deaths following immediately after operation and 39 at a later period. Of McCosh's laminectomies for fracture, 6 in number, two have recovered and four have died. (To be continued.)

[F. T. S.]

11.—Itob, in speaking of the gynecologist as a consultant, says that the gynecologist, no less than any other specialist must have a thorough broad training and experience in general medicine and surgery before taking up his specialty. Gynecology presents such a wide and important field that it requires the entire attention of the man who intends to obtain the best possible results. In order to appreciate the present condition of affairs one has only to compare the results obtained by any well known surgeon with those of the gynecologist in the first rank in a similar line of work, both as to morbidity and mortality. Taken as a whole the evidence will be found to be strongly in favor of the gynecologist. He claims that the family physician should always summon the aid of a gynecologist whenever the patient presents symptoms that suggest some pelvic inflammatory disease, and no improvement has taken place after a reasonable length of time from the course of treatment that is being pursued. He reports sample cases of conditions in which the diagnosis could only be made by a gynecologic expert. [W. A. N. D.]

12.—Randall writes on "the rationale and technique of pneumatic aural massage." This author states that of all the various measures and appliances of pneumatic massage, Seigle's otoscope is the best. This instrument enables the physician to see exactly what he is doing. He may note the response of the drum-head, whether it be muffled or intense, and determine the response of the malleus-handle. He believes that massage without ocular control should only be performed when the effect of the procedure has been studied well through the otoscope, and has proved itself harmless. The failure to secure good results with massage is often due to the lack of air within the tympanum. Therefore tympanic inflation is often indicated. In order to determine the result of massage, the condition of the patient should be carefully studied during the massage, after it is finished, and at the next examination.

[F. J. K.]

13.—Will be treated editorially.

14.—Galloway says that a surgeon is frequently more concerned about the anesthetizer than he is about his own work, that in more than half of the cases the patient is in greater danger from the anesthetic than he is from the operation; that in the majority of cases of death due to anesthesia the anesthetic has been administered by the unskilled; that the patient should not be brought profoundly under chloroform in less than five minutes, more than ten minutes being never required; that in chloroformization there is seldom a stage of excitement unless the patient be an habitué of alcohol, tobacco or some other drug; that it is unnecessary and dangerous to touch the globe of the eye; that the anesthetizer should be considered a consultant rather than an assistant; and that no man can safely administer an anesthetic and watch the operation at the same time. 1.—This article appears in conjunction with *Münchener medizinische Wochenschrift* and will be abstracted from that journal. [T. L. C.]

3.—Emanuel Senn reports two cases of operative treatment of saddle-nose. The condition is produced by trauma, which frequently causes a depressed fracture of the nasal

bones, or by disease, principally syphilis and tuberculosis. In the former, the supportive bone framework is destroyed, and in the latter, the alae. In case of fracture an immediate elevation of the depressed fragments, and their proper maintenance in their normal position, generally prevents this condition. When there is an old fracture of the nose in which the nasal bones have become deeply depressed there is usually considerable interference with breathing. The author gives his conception of the proper correction of this defect. Physiologic restoration of breathing and cosmetic result are both to be considered. This may be accomplished either by an intranasal or an extranasal operation. In recent fractures, the former method is preferable. Rhinologists are, as a rule, in favor of this plan in cases of old fractures of the nasal bones, but the author believes that an external incision is better in such cases, as it is an operation of precision. The external wound is small, and with careful suturing with a fine suture material, the scar in a few weeks becomes almost imperceptible. He advises a vertical incision, one and a half inches to two inches long made in the middle line of the nose over the depression, the skin and soft structures are to be dissected back carefully from the underlying fragments. With a narrow chisel the nasal bones are fractured at a point where they join the nasal process of the superior maxillary bone, care being taken not to injure the mucous membrane. A Kocher director, covered with gauze, is now passed into each nostril alternately, the fragments are thoroughly mobilized and the nose moulded into desired shape. A straight needle, armed with a medium silver wire, is passed through the nose underneath the fragments. Lead discs are placed at each end; the wire is tightened and fixed on the discs, thus supporting the fragments and also narrowing the width of the nose to the desired degree. The most important step of the operation is the placing of rubber tubes of the desired caliber in the nostrils. These will act as an intranasal splint and facilitate breathing. They are retained by adhesive strips fastened to the cheek. A plastic splint is also applied to conform with the new bridge. [T. L. C.]

4.—Charles Lyman Greene discusses pulmonary tuberculosis as an insurance problem, and lays especial stress on the value and importance of an early diagnosis. He believes that the insurance companies would save millions by paying more attention to direct contagion, and better methods of examination. He gives the early symptoms in the physical signs of the condition, and makes a plea for more thorough and scientific physical diagnosis.

[T. L. C.]

5.—Walter R. Griess discusses the value of antitoxin in diphtheria. He believes that antitoxin ought to be given as soon as the diagnosis is made with certainty; that children require larger doses, as their natural resources for fighting disease, are always less than those of adults. In mild cases of diphtheria 2000 units should be given as an initial dose, and if no improvement takes place within 12 hours, it should be repeated. All laryngeal cases, or cases in which prostration is severe, should have 4000 units as an initial dose, and 2000 units in 8 or 12 hours if there is no marked improvement. Intubation in children should be practiced before the child becomes exhausted, and if not successful, no time should be lost in making a tracheotomy. The value of a stimulant before performing such operations is not to be overlooked. He lays especial stress upon the fact that the results to be expected from antitoxin depend upon two things: (1) When used, in the course of the disease, late or early; and (2) in what type or class of case it is employed. [T. L. C.]

6.—William B. Stewart contributes a paper on the treatment of neurasthenia, in which he emphasizes the necessity of gaining the patient's full confidence, and the value of sympathetic attention and firmness on the part of the physician as well as adhering closely to method. He believes that the patient should be taught to think, move, eat, sleep, exercise and talk by absolute rule, and that these things are necessary as preliminary to successful treatment. It is necessary to relieve, as far as possible, the causative factors of the condition, and then inaugurate the physical methods of treatment, especially rest and exercise, and the writer lays stress upon the fact that the rest should consist of at least 10 hours per day and the exercise should be carefully moderated. As to climate, high elevations above 1000 feet, aggravate most cases. They do best at low elevations, and especially at the seashore. In some

nia and the drug habit must be carefully met. He emphasizes the value of massage and electricity, warm baths, hot foot baths, a cup of warm milk, or a slight walk before retiring, in place of drugs. [T. L. C.]

7.—A Hymanson reports a case of **purpura hemorrhagica**, and he concludes that the case proves the indisputable relationship of purpura, scurvy, peliosis rheumatica and allied affections. The patient, who was a boy of 18 years, presented marked gastrointestinal disturbance, colicky pains and an edematous condition of the joints. Prof. Jacob, who was called in the case, believes that the severe pain in the back was due to mild pancreatic hemorrhage. As to the remedial agents, codeln by the mouth, or morphia hypodermically, alone had some slight soothing effect. Ice bags on the abdomen gave relief, but caused retention of urine. The author advises the administration of vegetable acids in all varieties of purpura. [T. L. C.]

9. Report of Three Cases of Peritonitonal Hernia. JOHN CHADWICK OLIVER.

1.—J. Collins Warren discusses the **surgery of the spleen**. The various diseases of the spleen are reviewed and their surgical treatment outlined. The great frequency of small hypertrophy of the spleen among the Armenian inhabitants of Boston is mentioned and also the fact that in southern Italy this condition is quite prevalent. Operation of splenectomy is said to have been done in the most ancient days. It is said that sometimes the spleen was removed from runners for the purpose of giving them greater speed. Hagen has collected 360 cases of splenectomy with a mortality of 38.3%. Quite a number of large malarial spleens have been removed and in 64 of these cases operated upon after 1890 the mortality was 23.4%. Splenic anemia or splenic pseudoleukemia occurs in young adult life and is to be sharply differentiated from the anemias of infancy. Sippy (*Amer. Jour. Med. Sciences*, October, 1899, Vol. CXVIII, page 428) has collected 25 cases of splenic anemia. Osler (*Amer. Jour. Med. Sciences*, October, 1900) has reported 15. The symptoms of this disease with its insidious onset are next described. As the tumor increases anemia also increases, causing fatigue, edema of the feet and occasional temperature. Bronzing of the skin has sometimes been present. Ascites may develop and petechia and more rarely still hemorrhages from the stomach and intestines. Protracted diarrhea is a late symptom. A careful study of the blood is essential to a positive diagnosis and here a differential count of the white blood corpuscles is as necessary as an estimate of their whole number. At first there is a diminution of the hemoglobin with a lesser degree of the diminution of the red corpuscles. As the disease progresses there is an extreme drop in both hemoglobin and red blood corpuscles. The coagulability of the blood is much diminished. The white corpuscles are actually and relatively diminished and the differential estimate shows an enormous ratio between the young and adult forms. There should be no myelocytes. Atrophy and sclerosis of the Malpighian bodies has been noted by Banti which is in contrast to leukemia, in which disease, according to Cabot, the Malpighian bodies are increased. One of Osler's cases extended over ten years. Sippy regards the disease as fatal unless relieved by surgical interference. In seven of his cases splenectomy was done and five recovered. Osler recommends the operation only in chronic cases with recurrent hemorrhage. The author reports a successful splenectomy for

this condition. The diagnosis of splenic leukemia is made largely on the blood count which shows an increased number of white corpuscles with the appearance of the myelocyte. Splenectomy in this condition is most unfavorable, being almost invariably followed by death. Hagen reports 12 operations with only 4 recoveries. Death in nearly every instance was due to hemorrhage. Richardson reports a successful splenectomy for splenic leukemia. Banti's disease or hypertrophy with cirrhosis of the liver is next described. Banti's cases show an increase in the marrow of the long bone, beyond this there is little definite in the pathology of the disease. Hagen reports 16 splenectomies for Banti's disease with only three deaths. Wandering spleen gives rise to serious disturbance of the stomach and may occasionally produce intestinal obstruction. A peritonitis may also result from a twisting of its pedicle. During the last ten years there have been 13 splenectomies for this condition owing largely to the fact that the organ is usually hypertrophied and more or less diseased. In cases of abscess of the spleen where the organ is surrounded by pus or where it is not too tightly bound down by adhesions splenectomy may be performed. Where extirpation, however, means danger of infecting the peritoneum, opening and drainage constitute the treatment. In cases of rupture of the spleen, unless the rent be a small one and the hemorrhage easily controlled, splenectomy is to be performed. In the last ten years 4 cases of sarcoma of the spleen have been operated upon with operative recoveries and one death. Warren calls attention to the wide field for splenectomy showing that the operation is only contraindicated in such conditions as leukemia, cirrhosis of the liver and amyloid disease. The size of the spleen is much less a contraindication to operation than adhesions which it has formed to surrounding organs. Before removing the spleen Warren suggests that the hand should be passed under it and the organ turned over. In this way the vessels are rendered much more accessible and can be tied before the spleen is removed. The author thinks it has been shown that there is no difference in the resistance to infection from bacteria after splenectomy than before. One of the results of removal of the spleen is a temporary increase in the number of white corpuscles. Enlargement of lymph glands has frequently been noticed after splenectomy (Bolton, Warbasse) and occasionally the thyroid gland has increased in size. A report of 4 cases of splenectomy and one of splenopexy conclude the article. [J. H. G.]

2.—Harvey Cushing discusses the question of **prompt surgical intervention for intestinal perforation in typhoid fever** and reports a case. Attention is called to the fact that more than 2/3 of all the recorded operations for this condition have been done by American surgeons. The author thinks that the mortality of this operation is probably higher than statistics would indicate, because many of the isolated cases operated upon which ended fatally are not reported with the same certainty with which the successful ones are recorded. The results of the surgical treatment of this condition, however, have been so satisfactory as to make the operation one of necessity. In tabulating results it is suggested that a distinction be made between operations for intestinal perforation in typhoid and operations for acute diffuse peritonitis, the result of perforation. The result of perforation and all operations for the relief will greatly depend upon the form of bacterial infection which is set up, and this distinction cannot be made until the abdomen is opened and a culture made. It is thought that prompt intervention in cases of typhoid perforation will very shortly be the means of saving from 50 to 60 per cent. of these cases. Reference is made to the utility and ease of operating under the use of a local anesthetic. Even though no perforation should be found the abdominal section under cocaine will in no way interfere with the recovery of the patient. A case is reported by the author of a boy 20 years of age who from the onset of the fever showed marked abdominal symptoms. Within five days the leukocyte count increased from 5000 to 15,000. The patient passed some blood by the bowel upon several occasions. The baths were taken badly, the patient complaining of abdominal pain during immersion and being cyanosed after the bath. Upon one occasion the patient was considerably collapsed after a bath and at times there was considerable uniform abdominal rigidity and pain in the right iliac fossa. The patient's temperature dropped from 103° to 99°. Operation

was thought of at this time, but there did not seem to be sufficient indication for it. Subsequent to this collapse the patient passed a large amount of blood by the bowel. 45 hours later the patient's condition became serious, he vomited and the leukocyte count was 17,000. The patient was dull, his pulse was feeble and 140. Operation was done at this time under local anesthesia. A large perforation was found in the ileum and several ounces of pus were evacuated from between the coils of the bowel. There was also evidence of recent extravasation in the general cavity. The perforation was closed. A number of other thin spots were found over the ileum; so numerous were these that inversion was out of the question, so the operator wrapped the omentum around this portion of the bowel and fixed it with sutures. The wound was only partially closed and the diseased portion of bowel left directly beneath the opening in the abdominal wall. The patient did well after the operation, the leukocyte count dropping from 17,400 to 3000 in five days. The abdominal rigidity disappeared in two days. Eight days after the operation a fecal fistula developed at the wound. This promptly closed and the patient was discharged about two months after operation. The author thinks that it would have been better to have operated upon this case at the time of the collapse following the bath but excuses himself by a study of the patient's condition previous to this time and the fact that there were no very positive indications for operation. He asserts, however, that in another case, where there is a reasonable doubt, exploration will be made. Attention is called to the frequency of hemorrhage from the bowel in cases of perforation. The author thinks that one reason why better results have been reported from cases operated upon during the period from 8 to 24 hours after evidence of perforation is the fact that patients who survive perforation for this length of time have usually suffered from a mild bacterial infection or else the process has gone on slowly and been well combated by a peritoneal reaction. [J. H. G.]

3.—Bailey reports two cases of **accidental section of the spinal accessory nerve**, followed by serious disturbances of motion in the trapezius and sternomastoid muscles. This is unusual as in most cases the paralysis which results from section of this nerve is not particularly disabling. This is explained by the fact that the cervical nerves commonly participate in the supply of the trapezius and even when the sternomastoid is totally paralyzed freedom of movement of the head and neck is not abolished. When the spinal portion of this nerve is affected the trapezius and sternomastoid show a loss of power without symptoms referable to the larynx and pharynx. Among the producers of such a condition are fracture of the cervical vertebrae, cervical caries, syphilitic pachymeningitis, and such diseases as syringomyelia, locomotor ataxia, progressive muscular atrophy, and traumatic hematomyelia. Within the skull symptoms due to affections of both portions may result from basal lesions generally. An injury outside the skull, to cause symptoms referable to both branches, must be situated directly at the skull base. [F. T. S.]

4.—Bangs reports a case of a man aged 39 years who was born in Germany and admitted to the hospital for **retention of urine**. After a catheterization of the bladder a large tumor in the hypogastrium remained. By rectal examination the left lobe of the prostate is found to be larger than the right and its posterior and lateral margins cannot be defined from a mass in the pelvis with which it seems to be continuous. An incision was made from the umbilicus to near the pubes for exploration. There were a few adhesions to the intestines and the growth was distinctly adherent to the iliac vessels. Some 25 ounces of a clear serous fluid were withdrawn from the tumor by tapping. It contained many collapsed secondary cysts and four or five "pearls." The lining of the sac was rubbed dry and all the secondary cysts cleared away. It was found impossible to remove the sac, so the edges of its opening were stitched to the abdominal wall and drained. Microscopic examination showed the presence of hooklets in the fluid. The author has been able to find three cases which seem to correspond to the one reported. The case is regarded of prostatic origin because of the length of the urethra, viz.: 10 1/2 inches, because the obstruction to the urination was at the base of the bladder in the situation of the left lobe of the prostate, because the beak of the searcher rotated toward the right as it came in con-

tact with the left lobe of the prostate, because of the situation of the tumor, and because of the findings at the time of operation. The patient recovered, and at present a sausage-like mass can be felt extending from the posterior edge of the left side of the prostate backward and upward as far as the finger can reach. [F. T. S.]

5.—Murray emphasizes the very small percentage of cures following the medical treatment of **chronic amebic dysentery**, and recommends forming a complete artificial anus through an inguinal colostomy, preferably on the right side, to put the colon at rest, and in order to carry on a thorough and satisfactory local treatment of the colonic ulceration. If after four months of medical treatment the dysentery is not cured the case should be referred to the surgeon. The artificial anus should be left open for a long time and its subsequent closure should not follow until the ulceration is healed. This fact may be ascertained by the Kelly proctoscope introduced into both the natural and artificial ani, and by examining the irrigating fluid for the presence of the amebae and mucus. If the mesentery of the colon be too short to allow of the formation of a complete artificial anus, or if the ascending colon itself be ulcerated, an ileostomy may be performed. A case is reported which improved very much under the above recommended treatment. [F. T. S.]

6. Coolidge presents some new points in **tendon surgery**. He says it is wrong to turn away cases of infantile paralysis telling them that massage and electricity is all that can be done for them and recommending them to wear braces and shoes for the treatment of their deformities. In every case a special study of the muscles involved must be made, and living tendons transplanted to replace the paralyzed ones if possible. The operation should not be done until it is definitely settled which groups of muscles are affected. Regarding the amount of strength of the muscle to be grafted as compared with the work it will be called upon to do, much may be left to Nature and the gradual strengthening of the muscle to meet the demands made upon it. Grafting should preferably be done above the annular ligament, as this ligament will then hold the tendon in its place. A tendon may be carried by blunt dissection for quite a distance subfascially or subcutaneously. Beck tunneled the interosseous ligament in grafting a posterior muscle into an anterior one. The best method of joining the tendon is to pull the paralyzed tendon through a perforation in the normal tendon and apply sutures; or to cut the paralyzed tendon long, reflect it and suture it to itself, remembering to take a stitch at the bottom of the slit in the normal tendon to prevent its slipping. Chromicized catgut lasting from 1 to 6 weeks may be used. After operation the limb should be kept in a plaster cast for at least four weeks, and some appliance to keep the foot in its proper position worn for several months.

Tenotomy of a spastic muscle causes the spasm to disappear. When spastic paralysis involves the muscles of the pelvis and thigh, tenotomy of the adductors and of the internal and external ham strings may be done. Coolidge reports 2 cases. The first was a five year old male child with spastic paraplegia involving all the muscles of both legs. He was unable to stand alone. The tendo-Achillis on each side, both the adductor groups at the perineum, and both left and right, internal and external ham strings were severed and the right quadriceps extensor tendon lengthened. The immediate result was much less spasm of the right leg and attempts at walking improved. The second case was a male, aged 22, suffering from spastic paralysis as a result of a spinal injury. The adductors, both ham strings, and the tensor vaginae femoris of the right leg were severed and the quadriceps extensor lengthened. The improvement in this leg was so great that the other leg was operated upon in the same manner. The patient is now able to walk 150 feet. [F. T. S.]

7.—Brewer reports 11 cases which were mistaken for **appendicitis**. In two the symptoms were found to be due to renal calculus; in four to diseases of uterine appendages; in one to sarcoma of the ileum; in one to cholecystitis; in one to acute suppurative pancreatitis; and in two to general sepsis. Six were operated upon during a supposed acute attack of appendicitis, four after the attack had subsided, and in one no operation was performed, the condition being determined by autopsy. [F. T. S.]

8.—Meyer reports two cases of thrombosis of the femoral veins and three of intestinal obstruction following appendectomy. The first case was operated on during an

acute attack, the abdomen containing a small amount of turbid serum. On the ninth day after operation the patient complained of excessive pain in the left groin. Two days later edema of the leg and the infiltrated vein were noticed. Three weeks after operation the other extremity was attacked in a similar manner. The patient remained in bed two months. The second case was operated upon during an interval. In the beginning of the second week she also complained of pain in the left groin followed by the signs of thrombosis of the femoral vein. After about ten days the right femoral vein was similarly attacked. He mentions one case occurring in the practice of a friend, in which the trouble was located on the left side. He believes infection to be the causative factor of this complication rather than the mechanical theory of Lennander. The first case of intestinal obstruction occurred four days after an operation for acute perforative appendicitis and was due to kinking of the intestinal coils just below the operative wound. The second case occurred twelve days after an operation for perforative appendicitis. An abscess which at the time of the primary perforation of the appendix had been forming in the left lumbar region, had increased in size and, induced perhaps by an enema given on the twelfth day, perforated into the descending colon, the pus appearing in the stools. One of the coils of small intestine which had been under great tension while the abscess cavity was fully expanded became kinked when the tension was withdrawn. Another kink occurred farther up in the coil where the omentum had become adherent. The third case occurred one year after a perforation of the appendix. The obstruction consisted of a minute band which passed from the cecum over the small intestine to the root of the latter's mesentery. These cases all recovered.

9.—Oliver reports two cases of **properitoneal** and one of **interstitial hernia**. The first patient had been operated on for intestinal obstruction which was thought to be due to strangulation of the bowel through a rent in the mesentery. The patient died two days later. At the post-mortem examination the supposed rent in the mesentery proved to be the mouth of a hernial sac lying wholly within the abdomen. The sac and opening had been dislodged from the left inguinal canal and pushed into the abdominal cavity. The second case presented a strangulated inguinal hernia on the right side which was partially reduced by taxis. At operation the constriction was found at the internal ring which, with the parietal peritoneum, had been pushed away from the transversalis fascia. Case 3 presented an undescended testicle on the left side with a history of having had a hernia on the same side. A large mass was felt over the inguinal canal. Operation revealed a large mass of bowel between the external and internal oblique muscles. The last two patients recovered.

BERLINER KLINISCHE WOCHENSCHRIFT.

July 1, 1901. (No. 26.)

1. The Home Treatment of the Mentally Diseased. C. MOELL.
2. Vegetarian Diet for the Masses and the Proportion of Its Service. (Capacity Balance). BAEIZ.
3. Monolateral Innervation of the Occipito-Frontalis Muscle in Bilateral Total Oculomotor Paralysis. A New Spectacle for Ptoxis. SALOMONSOHN.
4. Rhinological Reports with Demonstration.

B. LEWY.

5. The Treatment of the Night Sweats of Phthisis with Tannoform. A. NOLDA.

1. C. Moell believes that the treatment of the **mentally diseased** in the family is possible independently and without connection with any institution. The households of the patients can be grouped together in one locality in the vicinity of an institution for exceptional cases. The patients will not have to run the gauntlet of prejudice concerning those mentally deranged, and in suitable cases this form of treatment may bring about recovery. In extreme cases the home treatment may be combined with that of the institution. [M. R. D.]

2. The vegetarian diet in Japan where the lower classes almost entirely subsist on vegetable food has formed the basis of Baeiz's observations. The main article of food in Japan is not rice, as is generally believed, because it is very expensive, but on the other hand consists of barley, buckwheat and the goya bean, the latter containing twice as much albumin as beef. As an illustration of individual

accommodation to new nourishment, Baeiz quotes the case of a sailor 18 years of age who had been confined to hard labor in a prison for 49 days. The physician offered to pay the man a certain amount of money if he would eat only certain varieties of vegetables. The sailor agreed, and for 49 days was fed on millet-pap, receiving it three times daily. After 49 days he had gained $1\frac{1}{2}$ pounds in weight, and was fully able to perform his work. This is, of course, an extreme example, but it shows what some human digestive apparatuses are capable of. The prevailing systems of investigations concerning metabolism, which, after all, consist in the mathematical calculation of ingestion and excretion are unreliable, as a variety of conditions may give similar results in figures. [M. R. D.]

3.—Salomonsohn states that **bilateral total oculomotor paralysis**, although not a rare affection, nevertheless is not so very frequently observed. They are, nevertheless, highly interesting because of the difficulty of locating the lesion. After a perusal of the literature on the subject he calls attention to a symptom which occurred in his case, namely, the **monolateral innervation of the occipito-frontalis muscle**. The patient had bilateral ptosis. Nevertheless he could lift the right upper eyelid far enough to be able to see with the right eye. This did not occur through the innervation of the levator palpebrae superioris, but by reason of the fact that the right eyebrow was drawn up together with the occipito-frontalis muscle, and when the finger was pressed upon the latter the innervation did not occur. The author appends an illustration of a pair of spectacles he has devised for enabling the patient to lift his right eyelid without calling upon the innervation of the occipito-frontalis muscle. [M. R. D.]

WIENER KLINISCHE WOCHENSCHRIFT.

July 3, 1901. (XIV Jahrgang, No. 27).

1. A Diaphoretic Cure for Osteomalacia. RUDOLF SCHMIDT.
2. The Etiology of Tubal Otitis Media. G. ALEXANDER.
3. A Calcareous Hematoma with Amyloid Degeneration of the Spleen. KARL STERNBERG.

1.—**Osteomalacia** has been treated by a number of drugs, by diet, oophorin, baths, and oophorectomy, according to the various theories. Lack of exposure to cold, and warm, moist applications have caused the greatest improvement, by influencing the vasomotor and secretory functions of the skin. Some hyperemia occurs in the intra-osteal and peri-osteal circulation. This may be due either to a weakness of the walls of the arteries and veins, or to obstruction to the course of these vessels through the compact Haversian canals. Therapeutics have been of no avail against this. Hypothetically, a superficial hyperemia should deplete that found in the deeper parts. Therefore Schmidt used **hot air baths**. He reports in detail two cases of puerperal osteomalacia, thus treated for six months, with complete recovery following. Insomnia, which is common in osteomalacia, was also cured by this treatment. Other means of producing diaphoresis should be followed by the same results, hot baths, hot drinks, pilocarpin, etc. [M. O.]

2.—Alexander reports two cases in full in whom **following resection of the upper jaw, deafness developed**. A catarrh of the Eustachian tubes followed the operation, on the side of the operation, causing an otitis media. Both membrana tympani were drawn in. The results of all treatment were negative. Alexander suggests that, in the future, care should be taken to leave the back part of the hard palate, some bone at least, that the dilator muscle of the Eustachian tube be left intact. Otherwise all such operations will induce one-sided deafness. [M. O.]

3. In the autopsy which he performed upon the body of a man of 70, who died of cholera following occlusion of the ductus hepaticus and ductus choledochus by gall-stones, Sternberg found a **calcareous hematoma and beginning amyloid degeneration in the spleen only**. This condition was probably due to the cholangitis, which had not existed long enough to have caused wide spread amyloid disease. [M. O.]

British Congress On Tuberculosis

(Continued from Page 356.)

A Query as to Whether Any Special Types of Pulmonary Tuberculosis and Its Complications are Unsuitable for Treatment in the Climate of the British Isles. By P. S. Hitchens, M. B., M. R. C. P. (Lond.). The author remarks that we have heard very much hitherto about the successes of the Sanatorium Treatment, but very little about its failures. According to some writers, one would imagine that there were no failures, but yet, even excluding the most advanced cases, and cases in which acute millary generalization and violent hemorrhages intervened, there were undoubtedly cases whose rate of progress was at any rate a considerable disappointment to one. Were these disappointing cases of any special type of the disease or its complications?

So far as his own small experience had gone, he had had two types of disease whose rate of progress had been a disappointment to him. In one type the disease had assumed a *bronchitic form*, in the other the disease of the lungs, in whatever form, was associated with persistent troublesome diarrhea with very irregular pyrexia. Two cases illustrating these types of disease were described. These cases had improved but very slowly, and not nearly so rapidly as other forms of disease, which might at first sight have appeared much more serious. With the exception of acute pneumonic cases, and cases associated with pleuritic effusion, he had had most of the ordinary forms of tubercular disease of the lungs and its complications under his care. The ordinary rapidly spreading broncho-pneumonic forms, chronic forms with excavation, and associated with severe tubercular laryngitis and tubercular peritonitis, had all done extremely well. He thought it would be of great interest to know whether others had had the same experience in other types of disease in whose progress they had been disappointed. Would these types do better in a more perfect climate, or would their progress be disappointing under any circumstances?

The excellent results obtained by the sanatorium treatment of consumption in the British Isles were now known to all, and he thought our knowledge would now be better advanced by discussing our failures than by boasting about our success.

Tuberculosis in the Maltese Islands. By Dr. Them. Zammit, Malta. The mortality from tubercle in Malta is exceptionally low. As the general death-rate is not very low, and as overcrowding, and the other debilitating agencies are by no means rare, the comparative freedom from tubercle must be due to the sum total of the telluric and atmospheric conditions which constitute climate. It is a well-known fact in the Island that tubercular diseases in the cattle and among the domestic animals are of rare occurrence. The percentage of deaths from tubercle in relation to the general death-rate is as follows:

During 1890 . . . 9.2	During 1895 . . . 6.8
" 1891 . . . 9.3	" 1896 . . . 8.1
" 1892 . . . 8.9	" 1897 . . . 8.1
" 1893 . . . 9.2	" 1898 . . . 10.7
" 1894 . . . 6.3	" 1899 . . . 9.4

The average being 8.65 for ten years.

Comparing this with the proportion of deaths from tubercle to the general mortality of other countries, we find that Malta stands at the bottom of the list. Detailed tables gathered from the official reports of the Public Health Department of Malta are given to demonstrate the fact.

Statistics and Results of the High-Altitude Treatment in Pulmonary Tuberculosis. Dr. Th. Stephani, Beauregard, Montana, Valais. From observation of 150 tuberculous patients treated at Montana from 1897 to 1900 the following statistics are obtained:

1. Form of the disease: Dry infiltrations, 34 per cent.; Bronchial types, 30 per cent.; Cases with cavitation, 17 per cent.; Congestive forms, 13 per cent.; Pleuritic cases, 3 per cent.; Abdominal forms, 2 per cent.; Tuberculous

adenitis, 1 per cent. The pulmonary lesions are more frequently bilateral (53 per cent.), and are more frequently situated on the right (27 per cent.) than on the left (20 per cent.). Laryngeal complications rank in the proportion of 15 per cent. Heredity is present less frequent (44 per cent.) than it is absent (56 per cent.). The bacillus of Koch was present in three-quarters of the cases, or in almost all those in which it was possible to collect the expectoration. The transmission of tuberculosis from man to man was obvious in 80 per cent. of the cases, a fact which proves the significance of contagion. The inquiry we have made on this matter shows how many barracks, convents, and business offices are common *foci* for the propagation of tuberculosis.

The part played by the pleura as a starting-point of the disease is sufficiently striking, for in 14 per cent. of the cases pulmonary tuberculosis commences with a pleurisy, and in 18 per cent. one finds injuries to the pleura described as having taken place several years previous to the development of the phthisis. 2. As regards appetite, there is a decided improvement in 97 per cent. of the cases, which showed itself in 67 per cent. by a progressive rise in weight. 3. Extension of thoracic capacity, due above all to rarefaction of the air, is frequently noted. 4. The cardiac troubles ascribed to high altitudes have only been noticed in one out of the 150 cases; it was a case of congestive tuberculosis, with malformation of the heart, that had already been diagnosed when in the plain. 5. Nervous affections have not been observed. 6. Hemoptyses do not appear to be any more frequent at high altitudes than on the level, since 35 per cent. had manifested them when at home, and not at the sanatorium; while only 1½ per cent. of the patients had hemoptysis for the first time at the sanatorium. 7. Fever is often combated most effectually by the Alpine climate—it has yielded, in fact, in 60 per cent. of our cases. 8. As to the results from the point of view of actual recovery, high-altitude treatment gives the following: 12 per cent. completely cured, 50 per cent. improved and half cured, 20 per cent. condition stationary, 18 per cent. condition worse, or died. The 12 per cent. of cures may be subdivided thus: Febrile cases with cavities and laryngitis, 0.7 per cent., or 4 per cent. of cavities. Congestive cases without fever, 0.7 per cent., or 5 per cent. of congestive cases. Bronchitic cases with fever, 0.7 per cent., Bronchitic cases without fever, 1.3 per cent., 2 per cent., or 7 per cent. of bronchitic cases. Cases of dry infiltration: Febrile with laryngitis, 0.7 per cent., afebrile with laryngitis, 0.7 per cent.; afebrile without laryngitis, 7 per cent.; 8.4 per cent., or 24 per cent. cases of dry infiltration. Pleuritic afebrile cases, 0.7 per cent., or 25 per cent. of pleuritic subjects. Cases of abdominal tuberculosis, 0.7 per cent., or 33 per cent. of cases of abdominal tuberculosis. It is, therefore, the cases of dry infiltration (a group which embraces ¾ of incipient cases of tuberculosis) that furnish the most hopeful percentage of recovery. Afebrile forms are more favorable than the febrile. Laryngeal complications, although troublesome, do not render cure impossible. Two-thirds of the cured cases were free from hereditary taint, which goes to prove that the non-hereditary cases have a better chance of recovery.

Conclusions:—1. The high-altitude treatment is indicated in all forms of tuberculosis. 2. The treatment yields on an average: 12 per cent. of complete cures, 50 per cent. of improvements, 20 per cent. of cases in which the tuberculous process is arrested, 18 per cent. of failures. 3. The more a case conforms to the type of an incipient tuberculosis of the pleuritic or dry form, free from pyrexia or other complication, and devoid of hereditary taint, the greater is the chance of recovery. 4. The treatment is only contra-indicated in cases of the asthmatic or congestive type accompanied by cardiac disease.

The Treatment of Consumption by Climate. By C. Theodore Williams, M. A., M. D., F. R. C. P., Brompton. Climate has in all ages been considered to exercise an important influence in the treatment of pulmonary tuberculosis, though opinions have differed as to the kind of climate which is most beneficial. In South America, since early times, arrest of tuberculosis has been produced by prolonged residence in the Andes (Archibald Smith, Guilbert, and Weber) without the aid of sanatorium and other treatment, and these successes must be attributed to climate and to climate alone. Numerous authenticated instances of arrest can also be shown as the results of sea

voyages, of warm and of cool marine climates, or of dry warm climates respectively; in fact, it has been proved that the arrest of tuberculosis has occurred in a variety of climates and under very different conditions. The main object is to determine under what climatic conditions arrest of the disease most frequently takes place, and what are the real causes of such improvement.

In all climatic treatment, care must be taken to bring the patient fully under the influence of the atmosphere, and to ensure a strictly open air life, with complete hygienic measures, whether in a sanatorium or elsewhere. The climate which best fulfils these conditions need not necessarily be a warm or a cold one, but should be dry, with abundant sunshine, admitting of much exercise, and producing appetite and muscular vigor. Tropical climates are excluded on account of their relaxing influence, and their favoring bacillar increase. The principal climates utilized for the treatment of pulmonary tuberculosis may be grouped as follows: I. Marine. II. Dry warm climates. III. Mountain climates. Of *marine climates* the temperate ones of the British Islands have been shown to be suitable for a large number of cases of chronic pulmonary tuberculosis, especially in its strumous form, even when accompanied by pyrexia, and for our countrymen and countrywomen the avoidance of long journeys and the certainty of abundant good food and of home comforts is a great recommendation. The warm climates of Madeira, the Canaries, and the West Indies are beneficial in catarrhal tuberculosis, but not as a rule in phthisis generally. Sea voyages are probably the most successful form of marine climates, and provided (1) the patient's cabin be well ventilated, so that he is sure of abundant fresh air by night and in stormy weather as well as by day, and (2) that the food be good and unvarying, and (3) that the voyage be in temperate and not in tropical seas; a sea voyage is often productive of large gain in weight and color and leads to arrest of tubercular disease. Sea voyages are most beneficial in (1) hemorrhagic phthisis, (2) in strumous or serofulous phthisis accompanied by affections of the glands or joints, and (3) in cases of chronic tubercular cavity where the disease is limited and unilateral.

Dry warm climates include that of the Desert (especially the Egyptian) and those of the Mediterranean Basin. The Desert climate is remarkable for its dryness, sunshine, and its purity and asepticity, and is especially adapted to open-air treatment. Owing to the radiation the extremes of temperature are often great. General improvement in consumptives is perhaps more striking than local, but diminution in the amount of lung secretion and reduction of cough usually takes place. The Desert climate appears to act more decidedly in preventing the spread of tubercular disease than in arresting that already present. It seems to most benefit cases of chronic cavity, especially in elderly persons and patients who are incapable of much exercise. The climate of the Riviera and of the Mediterranean Basin, as a whole, is cooler and more stimulating, but liable to greater vicissitudes of weather, though not of temperature, than the Desert climate. It is milder than the latter, and, compared to the British climate, it is clearer and brighter with a good deal of wind, but free from fog or mist, with a winter mean temperature from 8° to 10° Fahr. higher, with half the number of rainy days and four or five times the number of sunny ones. It can be recommended in chronic phthisis, especially when complicated with inflammatory attacks, in strumous and laryngeal phthisis, and to patients with rather extensive tubercularization of the lungs, who from feeble circulation, short-windedness, or advancing age are unable to bear the effects of a high altitude.

Mountain or high altitude climates vary according to latitude, but are all characterized by (1) diathermacy, or the increased facility with which the sun's rays are transmitted through the attenuated air, which causes a difference between sun and shade temperatures of 1° Fahr. for every rise of 225 feet (Denison); (2) by their asepticity, as shown by the preservation of meat for long periods; (3) by their physiological effects on the human body, as shown by the tanning of the skin, increase of both pulse and respiration rate, followed after a certain period of residence by a slowing and a deepening of the latter, and an extension of the thorax, also by an increase in the amount of urea and water excreted by the kidneys; more oxygen is absorbed and more carbonic acid expired by the

lungs. The effect on cases of early tubercular consolidation is remarkable, local pulmonary emphysema is produced around the tubercular nodules, and the healthy portions of the lung become hypertrophied, necessitating enlargement of the thorax which can be proved in several ways. Expansion of the chest takes place unless opposed by extensive lung fibrosis or pleuritic adhesions. It is suggested that the arrest of the tubercular disease is greatly owing to the pressure on the tubercular masses by the increasing bulk of lung tissue, which by emptying vessels promotes caseation and cretification of the tubercle. Accompanying these changes are the disappearance of cough and expectoration, improvement in digestion and assimilation, gain of weight, of color and of muscular, respiratory, and circulatory power. The high altitudes have produced the best climatic results of all climates in the treatment of phthisis, but they are most successful in cases of early tubercular consolidation, where they produce complete arrest in by far the larger proportion of patients, and in hemorrhagic phthisis, but they are not equally successful in cases of excavation, which require a longer sojourn to produce arrest. The high altitudes are much more beneficial to the young than to the middle aged of both sexes, males over thirty and females under twenty benefit least. The special effects above named have been noted in the Alps, the Andes, the Rocky Mountains, and are common to all mountain ranges. The period of sojourn for patients in any climate must depend on the conditions of the climate and of the individual to be treated, and in many instances a change of climate after a prolonged stay has many advantages. Contra-indications to the various groups of climates are enumerated. All climatic treatment should be carried out under as strict medical supervision as sanatorium treatment.

On the Comparative Influence of Climate and Individual Resistance in Experimental Tuberculosis. By Messieurs Lannelongue, Archard and Gaillard. The experiments which we have made in studying the influence of climate in the evolution of tuberculosis inoculated in the pleura of the guinea-pig have taught us that this influence is inconsiderable, and has not the importance which clinical experience has been wont to attach to it. They have enabled us, in addition, to observe remarkable differences in the progress of the disease and in the nature of the lesions in various animals of the same species, which have been similarly inoculated and submitted to the same conditions of climate and food. Certain of these animals offered such a remarkable resistance that it would seem that in their cases the infection had not matured, or had been spontaneously cured; some even increased in weight, and the records show that some died quite fat, whilst at the same time exhibiting lesions of generalized tuberculosis. In nearly half the number of cases the lesions remained localized in the thorax. Affections of the serous membranes, the pleura, pericardium, and peritoneum were extremely frequent, and exhibited the whole series of tuberculous lesions of such membranes met with in man—dry, sero-fibrinous, purulent and hemorrhagic forms.

A very special feature of tuberculosis in guinea-pigs, of which we have met with six examples, is rupture of the spleen, with profuse hemorrhage into the peritoneum. The spleen was often affected to such an extent that we have seen it weigh more than one-tenth of the animal. Most of the lesions met with have their counterpart in human pathology, one can compare these experimental results with what one finds in tuberculous human beings. It is therefore internal causes which together constitute the "soil," far more than external causes and climatic influences, which determine the nature of the lesions and general progress of the disease.

The chances of tuberculous infection are almost the same for a large number of human subjects; the onset is also very similar, but the progress of the disease is very different in individuals. If the number of men who resist it is relatively considerable, and larger than was the case with our guinea-pigs, it is because man is less liable to tuberculosis than the guinea-pig, and he is slowly infected and in small doses, and not in wholesale doses, as in our experimental inoculations.

Original Articles.

ON STREPTOTHRICAL INFECTIONS.*

By JOHN H. MUSSER, M. D.,
of Philadelphia,

Professor of Clinical Medicine, University of Pennsylvania

We have for some time been familiar with two streptothrical infections, actinomycosis, and the affection designated Madura foot. There have been accumulating, however, in the last few years, interesting accounts of various conditions due to other members of this group, and we must now recognize the fact that we are liable at any time to meet with pathogenic streptothricæ, other than those mentioned, causing very definite lesions.

Our knowledge of these streptothricæ dates from Rosenbach's communication in 1887, in which he describes as a cause of an erysipeloid condition an organism, growing as branching threads, but which from the branching being only apparent, not real, he calls a cladothrix. Rosenbach was able to produce the infection on himself and to obtain a pure culture of the organism.

In the following year Naunyn observed a branching thread-like organism in a red-brown stained area of the cerebral pia mater and in the endocardial excrescence in the heart of a girl dying of chorea. Baumgarten confirmed the observation. No cultures were, however, obtained.

Almqvist in 1890 obtained in culture from pus of cerebrospinal meningitis a streptothrix which he considered, however, a contamination. Growth on various media was readily obtained.

Eppinger's careful paper (1890) gives the most complete information of the nature of these infections up to that time. His case, one of abscess of the brain, was a glass polisher who two weeks previously had suffered from arthritis, and showed paralysis of the left side of the face and body, with distinct tenderness over the right half of the skull. From a large abscess of the brain, and of the spinal cord, cultures, pure, of a branching thread-like organism were easily obtained. In the semi-calcified bronchial and supraclavicular glands organisms of similar structure could be demonstrated. Eppinger's illustrations do not, however, seem to justify his naming his organism "cladothrix asteroides," as the branching seems more real than apparent. The experiments with animals gave rise to typical pseudotuberculosis.

No further demonstration of pathogenic streptothricæ occurred till Buchholtz's report of his findings in a patient taken suddenly ill with acute pleural pains, fever, bloody expectoration, and running for several weeks thereafter the course of an acute tuberculous pneumonia followed by empyema and death. Necrotic peribronchitis, cavity formation and an advanced tubercular-like condition showing caseous and ulcerating areas were present in the lungs. Some slight differences, however, between the condition found and true tuberculosis were the fact of the apices remaining unaffected, the irregular fatty-looking cavity wall, and the resemblance of the

infiltration to a fibrinous pneumonic state. In the sections a branching streptothrix could be demonstrated. Cultures were not obtained.

Sabrazes and Rivi re describe a streptothrix, cultivated from an abscess of the brain; also present in small abscesses of the kidney, and bronchopneumonic areas in both lungs. The subject gave the history of epileptiform attacks, and showed dulness, aphasia, vomiting, headache, paralysis and anesthesia of right arm and leg, some pain in neck and contracted pupil. The authors were able to obtain culture growths, though extremely scanty. This streptothrix, an ana robic organism resembled streptothrix actinomycosis in many ways, but did not show any of the clubbed forms. Some filaments could be seen within the leukocytes.

The same authors isolated an a robic streptothrix from the sputum and from a subcutaneous abscess, in a second case, the second streptothrix being pathogenic for small animals.

Ferri and Faguet report a case very similar to the first of those described by Sabrazes and Rivi re, isolating from an abscess in the brain of a patient taken suddenly with epileptiform attacks, pure cultures of a branching streptothrix which, however, was not pathogenic for animals.

Under the title pseudotuberculosis streptothricæ-hominum, Flexner reports a streptothrical infection resembling clinically pulmonary tuberculosis, with extensive consolidation. Some ascites existed. There was but little fever, and no expectoration. Autopsy showed a condition resembling closely tuberculosis: caseous pneumonia, small cavities, many areas of softening and small tubercle-like nodules throughout. In the omentum, liver and spleen were many similar nodules. The resemblance to tuberculosis was everywhere very decided, in the lesions and exudates, in the tubercles (?) the streptothrix was readily demonstrated. Flexner considers this streptothrix and that of Buchholtz morphologically most similar to each other. Cultures were not obtained in spite of all endeavors. Animal experiments were negative, but showed that the organism was apparently not tubercle.

A pathogenic streptothrix was shown by Scheel and Petruschky in 1897 at the Congress f r innere Medicin. The organism was from a woman with tuberculous history who had suffered from an influenza-like illness, with cough and left-sided pain and irregular remittent fever. To these conditions were added later cystitis and a pustular exanthem. A pleuropneumonic condition in the left upper lobe, an enlarged heart and spleen were the chief clinical signs. A penicillium-like organism was obtained from the sputum and the skin pustules during life, and, after death, from the lungs. Petruschky's description shows fine branched threads without fructification forms, belonging to the genus streptothrix. He considers the streptothrix in this case as being secondary to the primary influenzal infection.

An infection clinically identical with actinomycosis, but due to a different streptothrix is described by Fullerton in 1897. Pulmonary and cutaneous lesions, the latter an extension from the former, were present. Sputum and pus from the skin showed

*Read in part before the Cleveland Medical Society, Cleveland, 1901, and in part before the Chicago Medical Society, June, 1901.

The cuts illustrative of this paper will appear when it is published in the Transactions of the Association of American Physicians.

the sulphur-like grains supposedly characteristic of actinomycosis, but the cultural qualities differed distinctly. Fullerton designates his case one of streptothirical infection. Berestnew, and later Bruns, have described various similar organisms giving rise to infections which were considered clinical instances of actinomycosis. Berestnew's application of the term pseudoactinomycosis is objected to by Bruns on the ground that the streptothrix found is a species distinctly different from actinomyces.

From the sputum in a case of abscess or bronchiectasis of the right lung Rullman and Ziemssen isolated a streptothirical-like organism appearing very differently under different conditions, cladothrical at first, without branching on some media, with distinct branching on others. In the sputum small yellow-green masses of the mycelium, resembling somewhat the granules of actinomycosis, were readily distinguished. In animal experiments, supuration of lymph glands was produced, no evidence of tuberculosis being shown.

In a very complete paper Aoyama and Miyamoto describe the finding of a streptothrix in the sputum and in the contents of a lung abscess in a case rendered very obscure by the simultaneous existence of an aneurysm in the brain, which added to the very slight symptoms of a lung affection (slight fever and cough), convulsive seizures and signs of cerebral irritation. After intensification of pulmonary abscess streptothirical structures could be demonstrated in the mucopurulent sputum previously negative.

In the lungs, at autopsy, was a cavity toward the right base, with ragged, fatty-looking wall, surrounded by an area of gray hepatization and gelatinous pneumonia, with numerous bronchopneumonic areas in both lungs. Histologically, the absence of true tubercles and giant cells, numerous areas of necrosis, infiltration of the alveolar with small round cells or with fibrin and alveolar epithelium, infiltration of the septa with small round cells were the chief features. Aoyama considers the picture similar to that of Buchholtz, particularly as regards the gross appearance of the cavity. Pure cultures of a streptothrix producing in experiments pseudotuberculosis of the serous membranes, and organs were readily obtained. This organism resembles most closely that of Eppinger, but is quite different from that of Rullman, and that of Scheele and Petruschky in its cultural qualities. It is quite distinct from actinomyces. Like many of the streptothrices at present known, it is very resistant to acids, staining well with the differentiating stains used for tubercle bacilli.

In a second somewhat similar case, diagnosed tuberculous hemorrhage, pleurisy and kakke, Aoyama was able to find both tubercle bacilli and a streptothrix which, though not growing readily at first, could be cultivated from the pseudotubercles produced in animal injections.

A most instructive article, showing the pathogenicity, the morphological and cultural peculiarities of this group of organisms is that of Larkin and Norris. Of their two cases the first, a carpenter, gave the clinical appearance and history of gangrene

of the lung, following acute pneumonia. Extensive consolidation, fever, cough, very offensive sputa were present. The whole duration of this case was but a little over three weeks. The second gave a history of having had Pott's disease of the spine, a chronic cough for thirteen years, mucopurulent expectoration and night-sweats for several years. During the last year, aggravation of symptoms. Consolidation of both lungs could be made out and signs suggestive of cavities. The lesions of the two cases at autopsy can be summarized as acute exudative and necrotic bronchitis with bronchiectasis, bronchopneumonia composed of alveoli filled with cellular or fibrous exudate, more or less organized, productive inflammation and thickening of framework of the lung.

The most striking feature at autopsy, however, was the finding of large numbers of whitish opaque masses 3 to 5 mm. in size, attached to the necrosed areas of the bronchi, and throughout the necrotic and consolidated parts of the lung, and consisting of a network of filamentous organisms whose ends were often bulbous. Although not definitely branching at first, the organism in later cultures showed this peculiarity markedly. Most noteworthy in their experiments is the fact that intravenous injections of cultures or material containing organisms could produce pulmonary abscess and empyema. Intrathoracic and intratracheal injections produced readily similar lesions.

As showing the comparative frequency of myelitis suppurativa as a metastatic occurrence in bronchiectasis, Chiari describes an instance of such a condition due to a mixed infection with the diplococcus pneumoniae and a streptothrix. The subject entered the hospital with a history of a sudden onset of pain in neck and head; pain and impairment of muscular power in the whole right side of body, marked stupor and weakness, preventing examination and further history.

Autopsy, after brief illness of seven days, revealed large cerebellar abscess; multiple abscesses of spinal cord; spinal meningitis; complete obliteration of pleural cavities; pulmonary congestion; old scars at apices, with caseous masses; numerous bronchiectatic cavities in lower lobes; cylindrical enlargement of the whole bronchial tree, with large purulent collection therein, and marked reddening of the mucous membrane. Aural cavities negative. Culturally only diplococcus pneumoniae could be found.

In section of the affected tissue, and in the abscess walls could be demonstrated in addition to these organisms bundles of thread-like branching structures which frequently could be seen to be completely within the capillaries. Thrombosis of some of the larger vessels and marked inflammatory reaction about the "bundles" were also demonstrable. No actinomycotic granules or rosettes were to be seen. The structure of the mycelium was such however, that Chiari considers the streptothrix to stand in close relation to or to be identical with actinomyces. He also sees a close resemblance in some of the lesions of his case to the histological changes described by Eppinger. Reference is also made by this author to a case in von Jaksch's clinic

diagnosed as meningitis suppurativa in which a bronchiectatic cavity was suspected of being the focus of infection from which the suppurative meningitis might have arisen. Section confirmed the diagnosis, but disclosed in addition a large abscess in frontal lobe. The pus of the bronchiectatic cavity and of the abscess, the abscess wall, and the inflamed bronchial walls showed structures closely resembling those of Chiari's case. No cultures were obtained.

Ucke (*St. Petersb. Med. Wochens.*, 1901) has met with streptothrice in various conditions; in two cases, one of pulmonary abscess, with purulent pleurisy; the other, one of pulmonary gangrene, organisms were abundantly present in the sputum; it could be demonstrated also in the purulent exudate of the first case, and in the gangrenous and inflamed tissue of the second. Ucke also relates the finding of streptothrical organisms in two later cases of gangrene of the lung, in the expectorated matter and in the contents of a subphrenic abscess following duodenal perforation, and breaking through into the lungs, and in the tissues from a case of noma; only in the last mentioned instance were cultures obtained. Perthes (*Archiv für Klin. Chir.*, 1899) is quoted by this author as having also obtained cultures of streptothrice from cases of noma.

The pathogenicity of all these varieties of streptothrices and their relation to infections and lesions described is very evident, though cultural and animal experiments are lacking in some of the earlier observations, and it is clear that actinomycosis and madura foot can no longer occupy their isolated positions as examples of streptothrical infections. The pre-ilection of these organisms for certain regions or systems of the body is very apparent, the *lungs*, the *brain*, and the *skin* being most frequently affected; the *brain*, however, more often as a metastasis in cases of primary pulmonary or bronchial gland infections. In Rosenbach's case, "erysipeloid," the skin alone was involved. Scheele and Petruschky's patient showed pulmonary and cutaneous lesions, the latter a pustular exanthem. The actinomycotic-looking skin infection described by Fullerton, was probably due to an extension from the pulmonary lesions through the chest wall. Ferri and Faguet's case showed in addition to pulmonary lesions a subcutaneous abscess.

The *pulmonary lesions* in which the streptothrices have been found either alone or with other organisms show considerable variety; broncho-pneumonia, extensive consolidation, abscess, bronchiectasis, empyema, and necrotic bronchitis. The histological characteristics of some of these have been already considered, and the resemblance to and difference from tubercular infections pointed out.

Fullerton's case, clinically so like pulmonary actinomycosis, did not come to autopsy.

The lesions in the *nervous system*, practically always metastatic infections from pulmonary or bronchial gland disease, have been abscess, meningitis, or large areas of softening from thrombosis. No special peculiarity in the formation of the lesions is described. They have been most often met with in the cerebral region. In one instance both cerebellum and spinal cord were extensively affected, spinal meningitis occurring as well. Almquist's or-

ganisma was isolated from the exudate of a cerebro-spinal meningitis. The formation of "tubercles" is not described in the lesions of the nervous system, though in Eppinger's case the cerebral lesion resembled a broken-down tubercular focus.

But few other lesions are described. General "tubercle-like formations" throughout the peritoneum and abdominal organs have occurred, and in experiments pseudotuberculosis has been frequently reproduced. An abscess of the kidney was noted in one instance. Naumyn found an *endocardial excrescence* containing a streptothrix in his case.

From a clinical stand-point but little distinctly new is presented in streptothrical infections. The cutaneous lesions of madura foot, the cases of Rosenbach, Ferri and Faguet, Scheele and Petruschky, the cutaneous expression of actinomycosis, the actinomycotic-like skin infection of Fullerton, show some distinct differences. The pulmonary infections with their secondary accidents are all more or less hidden under the mask of a tubercular process, acutely termed pseudotuberculosis, or resemble some one or other of the number of pulmonary lesions, such as abscess, gangrene, or bronchiectasis, but the detection of the streptothrix and its mycelial masses is as diagnostic as the demonstrations of tubercle bacilli. Not all instances reported have been primary infections. In many the streptothrix may have been a very late invader. Many instances of streptothrical infections have probably passed unrecognized, owing to its peculiar tinctorial and cultural reactions. Rullman, Ferri and Faguet, Aoyama, Scheele and Petruschky were able to determine the nature of the disease in their cases by the findings in the sputum, as was Gwyn in the case we herein report.

The position occupied by the streptothrice in bacteriological classification is one between the moulds (hyphomycetes) and the bacteria, to both of which organisms they show some resemblance; to the former, in that they develop from spores into cylindrical dichotomously branching threads which alternately grow into colonies of masses of radiating filaments (the sulphur granules of actinomycosis.) Some of the threads, however, became "fruit hyphae," breaking up into chains of round spore-like bodies. To the latter (bacteria), in appearing as homogeneous threads resembling the filiform bacteria, which in old cultures may break up into shorter bacillary and coccus-like forms; in lacking a doubly contoured membrane and in not being composed of hyphae filled with fluid and granular contents separated from each other by partition walls. Unfortunately for this classification other organisms, bacillus proteus, diphtheria, and tuberculosis may occasionally show branching threads, and the latter has been described as showing figures almost indistinguishable from those of actinomycosis.

Of the genus streptothrix there are probably many species showing more or less marked morphological and cultural differences, as is well instanced in the now numerous streptothrices found in the lesions of actinomycosis and in the description of the various streptothrices in the above-mentioned cases. Some are readily cultivated; others can only with difficulty be grown on special media. Of most im-

portance to the clinician is the appearance of the mycelial tufts or granules in the discharges from the lesions, and the ready demonstration of the organisms therein. Many of the organisms are very resistant to acids and stain well by the stains used for detection of tubercle bacilli. Others are less resistant and are better revealed by Gram's stain. It is possible and probable that many instances of streptothirical pulmonary infection have been passed unrecognized, the organisms either having been considered tubercle or not having been revealed at all.

To these reported instances we wish to add the notes of two cases, one of which, though incomplete from lack of post-mortem observation, is yet of interest as demonstrating the possibility of recognizing the more or less obscure conditions met with in a pulmonary streptothirical infection; the other as showing the doubtful symptoms and rapid course of a localized cerebral infection by these organisms. The cases described so far in this country have only been recognized at autopsy. One may, however, as in the first case and in those of several of the foreign authors, detect the organism in the sputum and at least presuppose the nature of the infection.

CASE I.—J. T., aged thirty-seven years, male, married; very active in business; under the care of Dr. Dercum for mental disorder of several months' duration. I was asked to see him September 25th because of slightly increased respiration, pulse-rate, and temperature without apparent cause. Physical signs of bronchitis of very moderate amount were found. A slight morning cough was observed. The temperature until October 30th was about 99.4-5° to 100.1-5° in the evening; the pulse 100 to 125. The mental symptoms, confusion, and some excitement continued. He gradually became more dusky and the respirations more frequent. He had sweats during this time, and lost weight. The physical signs of bronchitis became more marked and the heart became dilated. On the evening of September 30th the temperature began to rise, reaching 101° October 3d. Physical signs of broncho-pneumonia developed, and death took place October 6th from exhaustion, due to dilated heart, which also caused edema of the lungs. The blood, the urine, and the sputum were examined as frequently as the state of the case permitted. Of the first two, nothing could be obtained to throw light on the case. The urine was always of normal specific gravity; contained a trace of albumin, no sugar and a few hyaline casts. The blood did not show leukocytosis. The one count reported is typical of all. The hemoglobin was 80 per cent.; red blood-corpuscles, 4,572,000; white blood-corpuscles, 3200. Of the whites there were, polymorphonuclear, 79 per cent.; small mononuclears, 17 per cent.; large, 3 per cent.; transitional, 1 per cent.

The sputum was studied most carefully by my associate, Dr. Norman Gwyn, and to him I am indebted for the suggestion of the nature of the infection. His report is as follows:

The sputum first obtained was small in amount, yellowish, homogenous looking; not foul, and contained no blood. No granular masses were present. Unfortunately, after the second day the stuporous condition of the patient seemed to prevent the collecting of pulmonary discharges, the later specimens being only nasal and buccal secretion. The first examination showed apparently a few thin tubercle bacilli retaining faintly the red stain of carbol-fuchsin after counter-staining with Gabbett's methylene-blue. Owing to the illform appearance of one of these, further examination was made and revealed, in addition to small rod-like forms, some definite branching structures resembling those pictured by several of the before-mentioned authors. No rosettes or club-like bodies were present. Many presented bevelled ends and were present as short filaments. By Gram's stain, principally, rod-like forms, containing the round coccus-like bodies (polychromatosis), were to be found. Some showed true branching. The organisms were extremely few. The rod-

like forms, by themselves, could readily be mistaken for tubercle bacilli. Only in the specimens stained by Ziehl-Nielsen and Gram's method were definite streptothirical filaments found. Great numbers of streptococci and pneumococci (?) were present, which caused the death of the guinea-pig in ten days without any signs of streptothirical or tubercular lesions. As I have mentioned, after the first two days no true sputum was obtained. After the second day the nasal and oral secretion showed no organisms like those found in the specimens of the first days. Cultural experiments had no results. The definitely branching structures and the appearances presented by Gram's and Ziehl-Nielsen stain, together with the resemblance to previously described streptothirica, induced us to suppose that we had to do either with a primary streptothirical infection or one secondary to a streptococcus infection of the bronchial tract. The possibility of these organisms being branched forms of the tubercle bacillus must also be considered.

CASE II is of extreme interest, and is the first of its kind to be reported in this country. It is, however, a very accurate picture of that described by Sabrazes and Riviére, and is very similar to those of Eppinger, Ferri and Fagnet, Aoyama and Chiari. Clinically it is of importance as showing how large an area of the brain can be affected without giving rise to localizing symptoms, and how different the diagnosis of such conditions may be. Further, it may explain the nature of some of those instances of cerebral infection, particularly abscess, in which neither by culture nor by animal inoculation can an infective agent be discovered. It is unfortunate no complete autopsy could be obtained to disclose if possible primary infection in the lungs or bronchial glands, were a possible condition.

The history of the case is as follows:

CASE II, single, aged twenty-four years. Complaining of an attack of loss of consciousness, with later, nausea and vomiting. His father had died of pulmonary tuberculosis. He had always been fairly well; habits good; had gonorrhea some years ago; no lues; no history of lung trouble; no ear disease. Had some small operation on nose recently.

Was quite well up to Wednesday, February 6th, when he had severe headache. The following day while at work he felt uncomfortable, retired to an adjoining room, and in a few moments lost consciousness, falling to the floor and biting his tongue. He was quite alone, so that nothing further could be ascertained. The patient felt dazed and stupid and noticed numbness of the right arm and leg, with some twitching of these members. On Friday he felt better; on Saturday and Sunday he was much the same. On Monday, the 19th, another attack distinctly convulsive and resembling epilepsy, occurred. The numbness of right arm and leg was a little more pronounced, and the occasional twitching was evident. There was slight headache, no chills, no cough, no pain or discharge from the ears, no eye symptoms.

Seen by Dr. Dercum at this time, no definite localizing symptoms could be made out. Previous condition persisted. There was no fever. The patient remained fairly well and was conscious. Pupils were equal; tongue heavily furred. The pulse was fair and the patient seemed to be improving. There was, however, slight hyperesthesia of the right side.

On Wednesday morning about 9 o'clock, after a fair night, there was, according to the nurse, a sudden collapse. The pulse could not be felt at the wrist. When seen half an hour later the pulse was very slow (30 to 50), very irregular, but of fair volume. The patient was semi-conscious, answering only when shouted at. The patellar reflexes seemed exaggerated, especially on the right side. There was marked hyper-extension of both feet. The

Babinski reflex was marked in the left leg; Kernig's sign well marked; very decided ankle clonus. Heart, lungs, and abdomen negative. Feces and urine were being passed involuntarily; some cyanosis of the nose and ears beginning. There was no rigidity of the neck, nor any tenderness over the skull. The examination of the eyes by Dr. de Schweinitz showed deviation of the left eye; pupils negative; very marked edema of the disks, probably due to meningitis. The patient was unconscious by evening, pulse was irregular and variable; distinct Cheyne-Stokes respiration. Prof. Hare joined in the consultation.

Lumbar puncture was performed. Two ounces of turbid fluid contained a few leukocytes, but no bacteria were obtained. There was immediate improvement, the patient regaining consciousness and remaining so until 6.30 next morning, Thursday. Lumbar puncture was repeated, with no improvement. The patient lapsed again into a semi-conscious state; rigidity of the right side became quite marked. Occasional convulsive movements were, however, sometimes, seen on the left, and a general convulsion, apparently of pontine origin, occurred. The hyper-extension of the feet was extreme, the dorsæ of the feet being level with the tibiae. No rigidity of the neck; reflexes still exaggerated; Babinski's reflex still present. The patient gradually failed, dying at 6.30 P. M. on Thursday, one week from the onset of the first convulsion.

The temperature, though subnormal at first, began to rise in the last three days, and for twenty-four hours before death was between 103° and 105°. The pulse increased in frequency meanwhile, but lost very much in volume. Apart from the slight deviation of the left eye, slight impairment of sensation on right side, no paralyses or localizing symptoms were observed.

The autopsy and the histological, cultural, and experimental examinations were made by Dr. R. M. Pearce, to whom we are indebted for much care and great skill in prosecuting the inquiries.

Head only Examined. Scalp and calvarium not noteworthy. Dura mater normal; pia normal; posterior and upper hemisphere prominent. At a point just posterior to upper portion of the fissure of Rolando is an area 3 cm. in diameter, which is fluctuant, grayish-yellow in color. On section there is found at this point, principally in the white matter of the hemisphere, but also involving the cortex, a cavity $3\frac{1}{2}$ cm. in diameter, containing a thick fluid, the first portion of which to escape is chocolate colored, the remaining portion is grayish-yellow and of the consistency of oil. No granules resembling those of actinomyces were present. The cavity is lined by a thin greenish-gray necrotic membrane, beneath which the brain tissue is much infected. The odor of this pus is exceedingly foul. Brain-tissue surrounding abscess for the distance of 2 to 3 cm. is softened and yellow in color, though there is apparently no direct extension of the inflammation.

Microscopically there is no inflammation of the pia over abscess. The rest of the brain on section is normal. There is no evidence in the vessels of the brain of arterial disease, thrombosis, or embolism. Bony ears are normal, and nowhere in the skull is there evidence of necrosis or bone-disease.

Smears from the abscess contents showed no tubercle, and only after prolonged search and staining by carbol-fuchsin, followed by Gram's solution and decolorized by aniline oil, could anything be made out. In one of these specimens was found a large ball-like and tangled mass, made up of long, thin filaments, staining irregularly. There is some suggestion of branching at the periphery of this mass. Only the one clump of these organisms was found. Cultures, aerobic and anaerobic, were quite negative.

Inoculations of two guinea-pigs were made, subcutaneous and intra-peritoneal. The first of these died in nine days, nothing suggestive being found; the other being killed after thirty-two days, and showing nothing but a few milary nodules at point of inoculation in the peritoneum. No evidence of tuberculosis in either animal. Cultures from both were negative.

A histological examination of the abscess wall showed the inner edge to be composed of necrotic pus cells. Indicating its chronicity, the deeper layer of fairly well preserved pus cells, lymphoid cells, and occasional endothelial cells. In the adjoining brain tissue lymphoid and plasma cells were quite numerous. About the blood vessels at periphery of abscess are many lymphoid and pus cells.

The surrounding brain tissue shows degeneration with polymorphonuclear leucocytes. No evidence of tubercle, or tubercle bacilli.

Sections stained with carbol-fuchsin, potassium iodide, and iodine and aniline oil show in one spot a large mass of threads radiating from a common centre. At the periphery, where the arrangement of individual elements are loose, they appear as long, thin threads, with small irregular staining. The general appearance is that of the centre of a colony of actinomyces. No clubs or rosettes are, however, present. Along the edge of the abscess wall a few single threads, similar to those in the original smears, were found.

In the study of the previously reported cases, and those of the writer, two interesting questions arise. First, is it possible that the cases hitherto reported as sterile abscess, in which it was thought the micro-organisms had died out, were cases of streptothirical infection. The experience of Dr. Pearce tends to this view, and that in previous examinations these organisms were not found. In his investigations Dr. Pearce made one hundred sections of the abscess wall before finding a colony, and nearly one hundred more before finding another. Smear after smear was stained to the number before colonies were detected. Moreover, the most recent writer, Ucke, has found the streptothrix in liver abscess, brain abscess and in noma infections, the pus of which has so frequently been found sterile.

Second, in Case 2, the cerebral abscess, the course was afebrile. This is a well known clinical fact of this affection, and is it therefore not possible that in abscess of the brain, in which the course is afebrile, the infection is streptothirical in origin? Moreover, may not abscesses in other locations, as the liver and lungs, and gangrene as that of the lungs in diabetes, be not of similar infectious origin? It seems in the cases reported thus far in the literature of the infection when fever was present there was a mixed infection, as those of streptococcus, pneumococcus or the like.

III. That, in the pulmonary cases especially, death is due to a mixed infection.

IV. That, so-called sterile abscesses may be instances of streptothirical infections.

V. That afebrile processes may be due to this infection, or, conversely, this affection may be unattended by fever.

VI. That, the morphological relations to tubercle bacilli and allied organisms must be remembered.

VII. That clinical observation and laboratory studies have yet to determine the clinical course of the streptothirical infections and their relationship to other streptothiricæ on the one hand, and to tuberculosis on the other.

They are not unlike other streptothirical infections, if these clinical facts are true, in that in actinomyces, for instance, we find frequently a chronic afebrile course.

These questions are as yet sub judice and require for their settlement laboratory investigations and further clinical observation, particularly in the light of the more recent studies. As a suggestion of the nature of the infection the question of leucocytosis should be looked into, therefore, although our cases present no facts.

It seems, therefore, worthy to conclude:

I. That the streptothrix in some varieties is path-

ogenic to man and gives rise to inflammatory, suppurative and necrotic lesions in (a) the lungs, and (b) the skin, and (c) by metastasis, probably, in the brain and spinal cord and rarely, other organs (the kidneys).

II. That, while this pathogenicity is more than likely and is primary, yet it must be remembered, it may be a secondary growth in the course of other infections.

POST-TYPHOIDAL ULCERATION, AND ABDUCTOR PARESIS OF THE LARYNX.—TRACHEOTOMY—RECOVERY.*

By D. J. GIBB WISHART, M. D.,

of Toronto, Canada.

Professor of Laryngology and Rhinology, Trinity Medical College.

Examination of the larynx during the course of an attack of typhoid fever is seldom made, partly because of the slight character of the laryngeal symptoms but chiefly because of the difficulty of making a laryngoscopic examination, while the patient is compelled to lie recumbent.

The record of a case of ulceration of the vocal cord, attended by paresis of the abductors, is therefore worthy of mention, especially as the lesion itself is rare among the recorded typhoidal lesions of the larynx.

I am indebted to Dr. McKibbin, for the following notes:

F. S. Aet. 41. Glass-blower, married. Father died at eighty, of bladder trouble; mother at seventy-eight, of pneumonia, a brother at seventeen, of a tumor in the left side of the throat, occurring during convalescence from typhoid; the remainder of the brothers and sisters are all living and in good health. Has been always a healthy man, and has followed his occupation for twenty years. Height 6 ft. 3 in., weight 170 lbs. No history of syphilis. Consulted me on March 23rd, on account of run down condition. Quit work on April 6th, with symptoms resembling la grippe. On the 15th, took to his bed with symptoms of typhoid, and temperature of 103°, followed by a characteristic course for four weeks. On the 6th of May symptoms of laryngeal irritation developed, lasting three or four hours, and consisting of hoarseness, and a tendency to clear the throat. These attacks occurred twice a week, at night time generally.

About this time also pneumonic symptoms developed in the upper lobes of both lungs. It was thought that this might have been tubercular, but examination of the sputum was negative, while the blood gave the typhoid reaction. The temperature remained high throughout, becoming normal on the 20th of June. For the next two weeks convalescence proceeded steadily. Every few days a spell of distressed breathing would occur, requiring medicated steam inhalations to give relief. Throughout the whole attack, the patient exhibited a neurotic temperament, and the attacks of dyspnea were markedly periodic. The temperature remained normal till the 9th of June, and immediately subsequent to the operation, registered 100.45.

I was called by Dr. McKibbin, to see patient on Sunday, June 2nd. Found him lying prone, respirations increased slightly, expression anxious, voice hoarse. On palpation the neck revealed nothing, neither tenderness, swelling, nor flidity. The patient was able to sit up without increase of the dyspnea, but the tracheal tugging was marked. There was nothing noticeable in the mouth or oro-pharynx, except the anemia, which was decided, and extended to the parts bounding the laryngeal vestibule. The vocal cords were almost in contact and the patient seemed unable to abduct them except very partially. The cords themselves were congested, and appeared swollen and somewhat nodulated, the swelling being entirely confined to the inferior surface of the cords, the infra-cordal por-

tion of the larynx, appearing to be bounded on either side by a rigid wall, extending diagonally outwards from the free edge of each cord. The left cord was notched towards its posterior extremity, the notch being filled by a pure white slough, and measuring about 6 m.m. in each direction. The edges of the notch were congested, uneven, and undermined. The examination produced an expulsive cough, which cocaine allayed, and apart from this, there was no difficulty in making the examination. (The false vocal cords appeared unaffected except by the anemia. The right arytenoid was swollen on the external surface). The patient was nervous and weak, and the examination brought on some nervous excitement, which was followed by an attack of dyspnea. The patient was able to lie down, however. Directions were given to continue the steam inhalations. A menthol and cocaine oily spray internally, and cold packing externally were prescribed. Did not see patient again till the following Sunday, June 9th. The breathing had been much relieved for four or five days, since then gradually more embarrassed. The previous evening there had been a very bad attack of dyspnea, and the patient was much exhausted. The examination which was made again without any difficulty, presented a similar picture to that recorded above, with one exception, that a distinct crevice had appeared between the slough, and the cord. Abduction was more deficient than formerly, and the rim-glottidis was simply a narrow slit. Tracheotomy was advised, should the breathing continue embarrassed. At 3 P. M. the same day, the condition became so much worse, that unconsciousness set in, and when the patient arrived at the hospital three hours later, he was insensible, and practically moribund. The trachea was opened in the high position, without an anesthetic, and artificial respiration practised. After breathing was restored, the tube was removed, and an attempt was made to obtain a view of the vocal cords from below. This was not entirely satisfactory. There was no evidence, however, of either ulceration or tumor formation below the cords, the walls of the infra-larynx being smooth, and sharply leaning toward each other. The patient was kept in a tent bed, filled with steam, and vaporized lime-water, and made a steady improvement, being discharged on the 21st day. Repeated examinations of the secretions from the tube were made with a negative result, nor was any adequate explanation forthcoming, for the rise of temperature between the 12th and 14th days. The noisy respirations prevented any satisfactory examination of the lungs.

On the 10th of July the patient was examined in my office, and the following notes were taken.

Weight, 150 lbs, steadily increasing. When the tube is closed, the voice is almost completely restored, no difficulty in swallowing, no sensation of smothering, voice not easily fatigued. The nose is freely patent in both chambers, there is no anemia, or lesion on the septum; the naso-pharynx is roomy, the lining membrane thin, and very closely adherent, with some congestion in the middle line close to the choanae. The mucous membrane on either side of the septum, is markedly puffed about the middle. In the mouth and pharynx, the soft palate is anemic. The isthmus faucium is capacious, the membrane of the posterior wall is thin and pale, and streaked with a mucopurulent secretion from the naso-pharynx.

Larynx.—Epiglottis pale at the edge, the right half is folded back upon itself so that it appears as a line projected directly backwards from the central point of the apex, and thus partially conceals the cavity of the larynx. The right arytenoid is normal in outline, but somewhat anemic, while the left is so placed as to lie in front of the right, and its contour is somewhat blurred by swelling of the internal surface, the capitulum of Santorini, however, being plainly seen. There is no abrasion of the surface, and the color is normal, or nearly so. The vocal cords: both are slightly thickened, of a reddish pink color; the vocal process is plain in the right, but cannot be seen in the left, being probably hidden by the swollen, and misplaced arytenoids. The edges are even, and without abrasion or nodule. In phonation, the cords meet evenly, and exactly, but the right arytenoid appears to have the greater excursion, while the left has almost none.

The parts of the larynx below the vocal cords, the sinus pyriformis, and the ventricular bands, etc., present no abnormality.

*Read at the annual meeting of the Canadian Medical Association at Winnipeg. Published by special agreement with the Editor of the *Canada Lancet*.

On July 17th. Weight 160 lbs. Swelling of the left arytenoid lessened. Removed tracheotomy tube.

July 29th. Condition of throat as above. Improvement continued in every direction, voice still a little foggy, tracheotomy wound healed, patient dismissed to the country.

In examining the literature of this interesting subject, the most satisfactory remarks are those of Friederich, (1), who "divides the laryngeal phenomena occurring in typhoid fever into three main groups—catarrhal conditions, ulcerations, and palsies; edema and perichondritis being regarded as accompaniments or complications of one of the three main divisions, and quotes Luning, as to the percentage of frequency of the occurrence of these phenomena—from clinical statistics 3%, and from post-mortem examination, 17%."

He further states that "clinically speaking, simple catarrh, and superficial ulceration, are the complications most frequently observed, while deep ulcerations which lead to edema, and perichondritis, or which, when extensive, present the so-called diphtheritic form (laryngotyphus), are much rarer."

"The pharyngeal and laryngeal mucous membrane, is often attacked by catarrh in the beginning of the disease—characterized by intense redness, while the swelling of the mucous membrane is comparatively slight." Superficial ulcerations occur from necrosis of circumscribed portions of the swollen mucous membrane, and manifest a preference for certain regions—the faucial pillars—the free border or laryngeal surface of the epiglottis—the aryepiglottic folds,—and occasionally below the glottis; they are rarely seen on the vocal cords." "At first there is diffuse catarrh, the membrane is darker in color, and slightly swollen in the areas mentioned; the epithelium breaks down and exposes a small shallow ulcer, with a yellowish floor resembling herpes, these coalesce to form larger quite superficial ulcers, with clearly defined edges, without redness, or swelling of the adjacent parts."

Friedreich denies that these are the effect of decubitus, as there is no reason why, if we accept such an etiology, simple ulcers should not occur in any other disease attended with the same degree of prostration; or from contact and direct infection with typhoid bacillus, since the latter has only rarely been found in them; but believes that they are the result of a nutritive disturbance in the membrane, connected with the general typhoid infection. They are benign, and heal without leaving a scar."

Friedreich also describes a class of cases where the ulcer extends to the deeper structure, as the result of a mixed infection; these Eppinger styles "mycotic ulcers," they invade the deeper structures, and eventually destroy the perichondrium and cartilages," and are to be distinguished from a diffuse typhoid infiltration in every way analogous to the typhoid lesion in the intestinal follicles, and originate in circumscribed areas containing adenoid tissue. These infiltrations lead to ulceration, the ulcers being distinguished from the former group by the hardness and swelling of their undermined edges." "The healing of those ulcers leaves defects and adhesions."

"Paralyses of laryngeal muscles occur chiefly in the stage of convalescence and present no character-

istic type, the abductors must be regarded as most frequently affected." It is a peripheral paralysis—and prognosis as to recovery is favorable."

Lockart divides the lesions into two classes—specific and non-specific, according as they are the direct effect of the typhoid poison, or due to secondary bacteria, decubitus or diphtheria." In the specific lesions the adenoid areas are alone involved, in the sinus pyriformis, base of the arytenoids, ventricle of Morgagni, the anterior commissure, the inter-arytenoid space, the false vocal cords, and the lower part of the epiglottis. The process in these structures is identical with that in Peyer's patches." In the non-specific form, the lesions are catarrh, erosions, and perichondritis—the resultant scar persists.

Kobler (3) calls attention to the existence of a characteristic affection of the epiglottis in typhoid." So long as the infiltration of the epiglottis exists the typhoid process is active."

McBride (4) considers that the most "characteristic condition is infiltration leading to ulceration, and the parts most liable are the under-surface of the arytenoids, and marked destructive changes may occur without corresponding subjective sensations." He also quotes Bergengruen, "that the typhoid bacillus, cannot produce suppuration, as proved by the experiments of Klemm, but that it paves the way for attacks of the staphylococcus pyogenes aureus."

Lennox Brown, (5) expresses the view that, "laryngitis occurs at a late—probably also as a secondary—manifestation of typhoid fever. In many cases the lesions depend upon the influence of decubitus. There is a strong tendency to active ulcerations, these principally occurring upon the ventricular bands,—the lymphoid elements of the larynx are not only especially prone to be attacked, but they share the same morbid changes which occur in Peyer's patches."

Shurly (6) considers "paresis of the abductor muscles the usual form. The cause is either a neuritis, temporary lesion affecting the nutrition of the ninth nerve, or pressure from some adenopathy."

J. H. Hutchison (7) concludes that "catarrhal or diphtheritic inflammation, and sometimes ulceration are most commonly found in the posterior wall of the larynx, and may involve the vocal cords."

Watson Williams (8) records one case of "acute laryngeal symptoms with dyspnea, and extensive ulceration;" and records a second case with "the posterior third of both cords, and the anterior surface of each arytenoid ulcerated." He also quotes the opinion of Lucatello, that "the laryngeal lesions of typhoid are catarrh, infiltrations, ulcerations, diphtheritis, perichondritis, and paralysis—exclusively attributable to the specific microbe of typhoid." Williams suggests that this may be an explanation of a possibility of typhoid being infectious.

The case which I have recorded, does not correspond exactly with any of the above descriptions, for the vocal cord bore the brunt of the affection. It is to be especially noticed that there was no pain, no hemorrhage, no bright congestion of the pharyngeal and laryngeal membranes, no perichondritis, and no scar remaining.

The mal-positions noted in the detailed examinations, were present prior to the onset of the fever, at least there were no lesions present at any time, which would account for them, nor were they paralytic in appearance.

If the immobility of the cords was due to paralysis, the paresis was confined to the abductors, but the appearance may have been due simply to the swelling, and rigidity of the cords and sub-cordal structures. It has entirely disappeared, and the voice although gruff, is described by the wife to be quite as good as at any time prior to the attack.

The location of the ulceration on the true vocal cord is evidently one of the rarest forms of typhoid involvement.

There are several cases in which tracheotomy was performed, but in most of these it would appear that marked perichondritis was present.

LIGHT AND RADIANCE IN THE TREATMENT OF DISEASE.

By GEORGE G. HOPKINS, A. M., M. D.,

of Brooklyn, N. Y.

ARTICLE I.

THE TREATMENT OF CARCINOMATOUS GROWTHS BY ROENTGEN RAYS.

The development of the X-Ray, since its first introduction to the profession, by its distinguished discoverer, has only been in matters of minor importance. The discovery was practically complete when given to the world. But the therapeutic effects of this fluorescence have remained to be developed. Soon after the use of the tube became general, reports began to circulate, and cases were reported in which injury had been done to the patients on whom the radiography had been practiced. I began early to study these injuries, and my observations were recorded in a paper published in the *Journal* in the issue of January 6th, 1900.

Further experience during the subsequent twenty months, both in the laboratories of some of the best radiographers in England, and on the Continent, and in my own, have gone to confirm the statements made in that paper.

Having bestowed so much time in looking up the injurious effects of their powerful examination, I early began to consider how we could turn these destructive effects to therapeutic uses.

With this end in view I determined to make my first experiments in the treatment of cancer. But it is not right to advise an untried remedy in a disease where life is in jeopardy and its course so rapid as is often the case in carcinomatous infections.

This is emphasized by the fact that the most satisfactory cases for treatment by the fluorescence are those in which the glands in the neighborhood of the diseased area are not yet infected. These are the

very cases in which the knife has its best record. Hence my advice in the cases that came to me was the knife, as a cure by my treatment by the ray was then only a theory, *not a fact* as now.

It was only on refusal to have the knife used that I resorted at first to the use of the Röntgen ray in cases of carcinoma. From my experience with this method of treatment, I can now advise the use of the ray in these earlier cases, with a clear conscience. In advanced cases, I have never hesitated to use this method as it holds out the only hope we have of cure.

My first efforts were with a tube energized by electricity from the alternating current, but the results were not as satisfactory as I could have wished. My tubes were made by different makers, with special reference to this work, and were mostly soft tubes, and this is the kind I have come to use entirely for this purpose.

A change in the energizing force from the alternating current to the static machine worked by an electric motor has certainly increased the effect of the ray on the diseased tissue.

The time of exposure is a very important consideration in the treatment of this disease. At Hamburg, through the courtesy of Dr. Albers-Schönburg, I saw some skin cases under treatment. The time of exposure varied from ten to fifteen minutes; this is the general practice in Germany in treating skin diseases, particularly psoriasis, eczema and lupus. I have reduced my exposures from thirty down to fifteen and five minutes, more often the latter period.

My assistant and the parts of the patient which were not to be treated, I have found were well protected by several layers of lead foil, glued to paste-board or more flexible material, making an opening in this screen where the rays are desired to act. I have yet to see in my own hands, or those of my assistants, a case where any of the healthy tissues have been injured by treatment with an X-Ray tube.

In England I found that Prince of Radiographers, Dr. McKensie Davidson, using as a protective a mixture of red lead and plaster of paris. This makes a very cumbersome and unwieldy protective, but as he only used it to protect while making radiographs, it was not of so much consequence. Most of the metals offer resistance to the passage of the rays, hence many have been tried as screens. Aluminum was used by some in the early days of the science, as it offered many advantages on account of its lightness and pliability, but as it offers less resistance to the passage of the radiance than the glass of which the tube is made, it was abandoned because absolutely worthless as a protector.

The distance of the diseased portion of the body from the tube is also an important consideration.

In my exposures I vary the distance from twelve to thirty inches; this is altogether governed by the effect desired, and is difficult to lay down by rule. Where daily exposures are to be made, the tube should be at a greater distance from the patient, than where exposures are to be made at longer intervals. "The errors to be avoided are too long exposures, too short a distance between the tube and the patient, and improper apparatus."

The theory on which we advocate the use of a soft X-Ray tube in the treatment of carcinoma is, that their power to produce changes in tissue must be in proportion to the resistance which the cells of the tissue to be acted on offers to any destroying agent. Theoretically, the longer wave of the soft tube, as compared with the harder tube, has more destroying and disintegrating effect. It is well for us to bear in mind that but for the active cell resistance to disease germs, none of us would live many days. The phagocytes of the system when active and healthy protect us from infection and from destructive action of poisons that enter into the system, unless they enter in such vast numbers and quantities as to overwhelm these scavengers.

Carcinomatous tissue is composed largely of embryonic cells, whose molecules are unstable and can easily be destroyed, or made to take on a new arrangement. This new grouping either destroys completely these diseased cells or makes them take on healthy action, thus stamping out the disease.

Therefore, a current that is prolonged to too great a time limit, and is brought too near the patient, and is generated from an improper apparatus, may carry the effect of the X-Ray current beyond what is desired. This effect we often want where tissue is broken down, and necrosis of the parts has passed beyond the possibility of repair. If patients will come to us in the earlier stages of the disease we can in most cases work a cure.

When this method by the X-Ray is accepted as a general and safe treatment by the profession at large, fewer women will conceal the existence of a growth in the mammary gland than is now the case, as there is such an inborn dread in all of us of the use of the knife. The laity should be made to understand that there is another method of procedure in the treatment of malignant disease than by the use of the much dreaded knife. I am personally as fond of the use of the knife as any surgeon, where it is best for the patient, so I can lay down the above rule with more propriety than men who are opposed to, or, not skilled in surgery.

The following case illustrates the benefit of the X-Ray treatment in cases where there is no breaking down of tissue, and the mammary gland alone is involved, the axillary glands presenting no evidence of infection.

No. 8. Mrs. Aurille M., aged 68 years. Native of Vermont, married, has had no children, always healthy. Her grandfather died of cancer. Several months ago slight pains called attention to her right breast, which on examination proved to be somewhat enlarged. It continued to increase in size until it was twice as large as the left. She consulted me on the 22nd of January, 1901, as she heard I was using "electricity" in the treatment of cancer, and wanted my opinion. I was frank with her, and told her that the knife was the proven treatment, but that I was experimenting with the X-ray in such cases, not with electricity. She said she had come to me because she was not willing to subject herself to the knife, and wanted to try treatment by the ray even though it was in an experimental stage. The next day she took her first treatment. This was January 23d, and the exposure was 5 minutes, 24th 8 minutes, 25th 7 minutes, 26th 10 minutes, 28th 8 minutes, 29th 8 minutes, 30th 8 minutes, 31st 8 minutes. We could detect a change in the density and size of the gland by this time, and the breast felt more comfortable. February 1st, exposure 8 minutes, 2d 15 minutes, 4th 10

minutes, 5th 8 minutes, 6th 7 minutes, 7th 7 minutes, 8th 7 minutes. She was improving so rapidly, and the breast was so much reduced in size that I suggested an intermission of treatment for a week or ten days. February 16th she presented herself again and the condition of the tumor continued satisfactory. Treatment was 12 minutes, 18th 12 minutes, 19th 12 minutes, 21st 10 minutes, 22nd 10 minutes, and as she was going away for ten days on the 23d I exposed for 18 minutes. March 2nd 12 minutes, 13th 18 minutes, 28th, not having had treatment for two weeks I gave a 20 minute exposure. All the time the tumor had continued to decrease, and was nearly as small as the normal breast. As she was going to her country home for the summer on May 1st, I deemed it wise to give her a few more treatments and try to bring the right breast absolutely down to the size of the left. With this end in view I gave her the following treatments. March 30th 8 minutes, April 1st 10 minutes, 5th 10 minutes, 8 10 minutes, 10th 8 minutes, 12th 8 minutes, 16th 8 minutes, 18th 8 minutes. As the breast was practically reduced to the size of the healthy one and all disagreeable sensations had ceased I saw no further occasion for treatment, but cautioned her to report to me on the least increase of size, or return of pain in the breast. This she said she would do if there was any change during her country residence, as her city house was always open and she could come in very easily. This case I consider cured, and as it is typical, I report it very fully.

In all these cases the first effect observed is a decrease in the density of the tumor. This change in consistency governs very largely the time of exposure, for should we carry this process too far, necrosis of tissue would occur. This is a condition which we must studiously try to avoid.

When I started out with this method of treating carcinomatous growths with radiance, I had in mind the utter destruction of the diseased tissue producing a "white gangrene", and of the danger of this effect I warned my patients. Experience however has demonstrated that it is not necessary to carry the treatment to this extent even in advanced cases, as they will heal under less exposure than is necessary to produce complete destruction of the diseased area. This goes to confirm the theory that the "ray" produces a change in the molecules of the embryonic cells of the tumor. In cases that have broken down and ulcerated, the effect of the ray treatment shows itself very promptly. In these cases the exposure is not of necessity more prolonged than in milder cases, as one would naturally expect.

I have had a very interesting case where I have used a combination of the X-Ray and Finsen light. This case was a patient who had had the left breast amputated and the entire axillary plexus of glands removed, as they were involved in the disease. The extensive wound healed promptly but the cicatrix subsequently broke down and began to ulcerate. The necrosis was an inch deep. Yet under the combined influence of the ray and violet and ultra-violet rays of the Finsen apparatus, the cicatrix has completely healed.

A fungating cancer of the breast was recently brought to me for treatment, the hardened right breast was at least 7½ inches in diameter. The discharge was offensive; but after a few treatments with the X-Ray the character of the discharge changed and the odor disappeared; the fungating mass has retracted; the whole breast is softening

and the patient is relieved of all the pain and discomfort she was suffering. She says "if the treatment does nothing more than make me as comfortable as I am now, it is quite worth while."

On this class of cases I am not prepared to come to definite conclusions, but feel greatly encouraged by the results of treatment thus far.

This is a large subject, and only in its developmental stage. But I am sure we can be perfectly justified in advising our patients to use the treatment where the carcinoma is only local in its manifestations, with more expectation of success than with any treatment heretofore devised, unless it be the knife.

ON THE USE OF THE ROENTGEN RAYS IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.

By HUGH WALSHAM, M. A., M. D.,

(Cantab.), F. R. C. P. (Lond.),
of London, England.

Assistant Physician to the City of London Hospital for Diseases of the Chest
Victoria Park, E.; and Assistant Medical Officer in the Electrical
Department of St. Bartholomew's Hospital.

Since Professor Röntgen made known his brilliant discovery, now some five years ago, I have been at work on the use of the X rays in the diagnosis of pulmonary tuberculosis. I propose bringing before you this morning very shortly some of the results attained. The questions I proposed to answer, if possible were the following viz:

1. Can the Röntgen rays show tubercle in the lung?
2. If so, at what stage of their development?
3. Can the rays detect tubercle in the lung before the physical diagnosis already at our disposal?

Now obviously the first step to be taken in the attempt to answer the first question was to obtain a skiagram of a normal chest, to study its shadows, and endeavor to differentiate between the shadows cast by structures outside the thorax from those caused by its contained organs. The next was to take a skiagram of an undoubted case of pulmonary tuberculosis and compare the one with the other.

I will now, first of all, throw on the screen a picture of a normal chest. We see at once that the pulmonary image in health is quite transparent from apex to base, with the exception of a few ill-defined shadowy lines to the right of the heart shadow. These cardiac lines are seen more or less pronounced by all skiagrams of the healthy chest, and must, therefore, be considered normal. Now, on what do they depend? Are they caused by the lower division of the longer bronchi? I think not. If we look at a skiagram of a normal lung outside the chest, we see that only the primary division of the bronchi are seen, and, in addition to this, these cardiac lines are too low in position to be caused by the bronchi. I have endeavored to clear up this point in the following way: I took a skiagram of a dead body on the *post mortem* table; I then removed the sternum, opened the pericardium, removed the heart, replaced sternum and integuments, and took another radiograph. The lines still remained. I then opened the chest, removed the lungs, replaced the sternum, and

the integuments, and again radiographed the body. The final stage I show you on the screen. You see these cardiac lines still remain, and are caused, no doubt, by the junction of the pericardium with the pleura. They are much more distinct in the dead body, of course, as they are not in constant movement by the systole and diastole of the heart as they are in a living person.

The next point you will observe is the shadow of the scapulae is absent. Their shadow only complicates matters, and is better removed. This can be done in the following way: The patient lies in the prone position on the plate, the arms being extended and hanging over the end of the couch. In this position the scapulae are turned edgewise, so to speak, and their shadow removed from the skiagram.

The next shadow I should like to call to your attention is one shown well in this skiagram, and usually seen in the more muscular subjects. It is, as you see, somewhat triangular in shape, and extends upwards and outwards towards the axilla. By the stereoscopic method these shadows are seen to be outside the chest, and are caused, no doubt, by the anterior axillary folds. They are only seen, I think, when the patient is skiagraphed in the prone position with extended arms, this position naturally rendering the axillary folds thicker. Of course, the shadow of the pericardium with contained heart in the anterior position is well seen. I need only just mention it. The shadow of the diaphragm is also well seen. And here, in passing, I will make a short digression. It is not so much the shadow of the diaphragm that is important in pulmonary tuberculosis as its movements with respiration as seen with the screen. Now, if the diaphragm be watched with the screen, we see that it does not, as physiologists tell us, become flatter with inspiration. Its curve is always maintained unaltered; it plunges up and down piston-wise, and I now come to a point of great importance in the diagnosis of pulmonary tubercle. The movement of the diaphragm on the affected side is much less than on the non-affected or less affected side, and this when the disease is limited to one apex. Why this should be so, is hard to explain, but the fact remains.

I will now throw on the screen a picture of a case of pneumothorax, showing the depression of the diaphragm by the increased pressure in the pleural cavity. If you will look again for a minute at the picture now on the screen, you will see that the healthy chest in the living person is as clear as that of the dead body with thoracic viscera removed, showing that any abnormal shadow seen in the skiagram is due to some pulmonary change—in other words, the muscles and integuments of the thorax are transparent to the rays. Not so, however, with the dead lung outside the body, which casts a very distinct shadow, although transparent, in the living condition. At present I cannot offer any explanation of this curious fact.

There is one other shadow I will mention, and that is, we occasionally see an ill-defined curve shadow in women with large mammary glands. Here again the stereoscopic method shows the shadow to be outside the thorax, and therefore cannot be confounded with shadows produced by pathological changes in the lungs.

* From advance sheets furnished by our representative at the Congress on Tuberculosis, London.

I will now throw on the screen a well-developed case of pulmonary tuberculosis. You see at once there is a marked difference. The clear pulmonary image is obscured by flocculent shadow, punctate in parts. Now on what do these shadows depend? Are they due to tubercular consolidation or to patches of congestion of caseation or pleural adhesions or what? I have endeavored to answer these questions in the following way. On the screen before you is the skiagram of a tuberculous lung; nearly the whole of the upper lobe was caseous and breaking down. So we see that caseation throws a very dense shadow. The shadow, lower down, caused by grey and yellow tubercle, is nothing like so dense; still, as might be said that some of this shadow is due to blood congestion round the tubercular consolidation, I performed the following experiment. The lungs from a case of pulmonary tuberculosis were taken; one was soaked in water for some hours to break up the blood corpuscles, the vessels washed out until the water came away colorless. Both lungs were then skiagraphed, and I think you will agree with me that there is little or no difference between them. Again, it has been asserted that the blood next to the bones is the most opaque tissue of the body. With this assertion I cannot agree. Look, for instance, at the picture now on the screen. It represents a portion of a rib, a piece of muscle the same size, and a blood clot. My eye can detect no difference between the muscle and the blood clot—that is to say, clotted blood, which, by the bye, is more opaque than fluid blood—is more opaque to the rays than muscle. Again I took the lung and kidney which contained tubercle from the same case, and radiographed them together. The tubercle in the kidneys is distinctly seen, down to the minutest miliary tubercle which could be detected by the naked eye. Again, look at these lungs from a case of acute miliary tuberculosis. They show the tubercle scattered through their substance clearly enough.

(Fibroid, 2 Exhibits.)

Putting the above facts together, we may, I think, answer our first question by saying that the Röntgen rays can show definitely tubercle in the lung.

I will now throw rapidly on the screen some cases of undoubted pulmonary tuberculosis more or less advanced. I now come to the question of the detection of cavities in the lung. That the X rays can detect with certainty a cavity in the lung is now a fact beyond question. With reference to the size of a cavity, I would say that the rays can diagnose a cavity much smaller than can be detected by auscultation. The smallest I have yet met with is now on the screen before you. It is less than a small marble. The Röntgen rays are also of great use in judging the size of a cavity. Occasionally auscultation gives evidence of a cavity of large size, and we are surprised, on examining with X rays, to find that the cavity is a small one. This must mean that the consolidation round a cavity must conduct the sounds produced in the cavity far beyond its limits. Furthermore, it not infrequently happens that auscultation diagnoses a cavity which the rays show has no existence.

I will now pass on to the second question, viz., At what stage of development can the X rays detect tubercle; and here I am afraid we must admit that the very earliest stage in the development of the tuberculous process cannot be detected by the X rays, but this also applies to all our other methods of physical diagnosis. The first beginning of tubercle in the lung cannot be detected by this or by any other means at our disposal. There can be no doubt that the X rays are able to pick out in in shadow a very small tuberculous focus in the lung. I will give a few examples. The skiagram on the screen is from the chest of a man aged 28; he came to the out-patient room complaining of his digestion. On examining the chest there was nothing to be made out except perhaps a little weakening of the breath sounds at the right apex. I examined this patient radiographically, and had no difficulty, as you see, in diagnosing a tuberculous process at the right apex. The next case is that of a woman aged 34. In this instance there was a little prolongation of expiration, with some slight difference in the percussion note at the right apex. I was somewhat surprised, therefore, to find that there was extensive disease in the right upper lobe. The shrinking of this side of the chest is well shown, which was not detected on physical examination. The next two pictures are both from patients in whom pulmonary trouble was suspected, but which gave no evidence of its presence on stethoscope examination. The shadows, however, in each case are distinct, and later in their history the physical signs with the stethoscope became undoubted. I think, therefore, we are justified in saying that the X rays are able to diagnose really early tuberculous change in the lung. I think, also, that the Röntgen rays can detect tubercle certainly as early as the stethoscope, or even earlier, as the last two cases show. Now it may be asked how can you tell a tuberculous shadow from that of a new growth. This can be done only by the distribution of the shadow and by the history of the case. As with the stethoscope, we have to consider the history of the individual case before us, so with the X rays. Pray do not think for one minute that the X rays can diagnose tubercle off-hand; such, I am sure, is not the case. But I think that this means of detecting an early tuberculous shadow brings a little nearer the day when internal tubercle may perhaps be treated with chemical rays, as external tubercle—viz., lupus—is being treated to-day with such conspicuous success. In the future we may perhaps be able to say of pulmonary tubercle: "It comes as a shadow, so departs."

I will only detain you a few minutes longer; I have avisedly said nothing about methods of examination; I thought in an audience such as this it would be superfluous. I may say, however, that all the skiagrams I have had the honor to show you were taken with a coil giving a 14-inch spark between the terminals of the secondary coil. One word more and I have finished. I think in all cases of suspected pulmonary tubercle a skiagram should be taken. From an experience of over five years I am sure that a shadow can be detected on the photographic plate that would be quite missed on the screen.

SLOW PULSE. By Robert T. Edes, M.D., of Boston, Mass.—Concluded.

TABLE III [continued].

Cases of slow pulse, with or without paroxysms, resulting fatally, but in which no autopsies were made.

The President's Wounds.—After the first shock caused by the inhuman crime perpetrated upon President McKinley has passed, the question of paramount interest to every citizen is, what hope have we that this valuable life will be spared to the nation? In the light of surgical knowledge and experience with similar injuries, what are the chief dangers and on what ground can we place our hopes for the President's recovery?

The details received at the time of writing are not quite so full as we should like. From the information received, however, it seems that the crime was committed about 4 P. M., and about three hours after the ingestion of food. The wounds were caused by two bullets from a short-barreled revolver, fired from directly in front and at a range of about one foot.

The first shot struck the sternum at about the nipple line and was deflected, traveling just under the skin to a point immediately below the left nipple. The second bullet entered the abdomen at a point two and a half inches to the left of the median line, and at a level of about half an inch above the umbilicus. The would-be assassin and the President were standing directly in front of each other, and the weapon was held in the right hand. Arguing from the course of the first bullet, the course of the second, it seems almost certain, was from before directly backwards and from above slightly downwards. This would lead us to think that unless deflected after entering the body, which, however, is not very likely, its course would carry it through the lower anterior wall of the stomach a little to the cardiac side of the middle, through the stomach, making a wound of exit in the posterior wall a little lower than the wound of entrance. Then it would reach the posterior abdominal wall at a point near or at the left crus of the diaphragm, a little above the kidney.

The chest wound is probably not dangerous, for it seems to be merely a non-penetrating wound of the chest of a kind which, although painful and sometimes difficult to heal, is practically without mortality. One important fact which this wound shows is that the muzzle velocity of the bullet was not

very great, as evinced by the fact of its not penetrating the sternum, although fired from directly in front. This is not a favorable circumstance, for bullets of lesser velocity produce the larger and more ragged wounds.

The immediate dangers from such an abdominal wound are hemorrhage from an injury of the great vessels situated to the left of the spinal column, wound of the pancreas, which is usually immediately fatal, and injury to the spinal cord by penetration of the spinal canal by the bullet. Time has shown that all these dangers have been mercifully escaped, and now there remain only the secondary effects to be feared.

By far the greatest of these secondary dangers is peritonitis, yet there are two factors that give us hope that the President will escape this complication. These are an empty stomach at the time of injury and prompt operation by skillful hands.

The first of these is most important, as the empty stomach would, of course, cause less soiling of the general peritoneal cavity. Nevertheless there are many cases in which the contents of the stomach have extremely soiled the peritoneal cavity, in which recovery has followed operation. In fact, the stomach is less apt to contain virulent micro-organisms than any other part of the intestinal canal. The statistics of early operation for perforation of the different parts of the alimentary canal are very gratifying, and even in the perforations of typhoid fever, where there are present many factors which would lead us to fear a lethal termination, which are not present in President McKinley's case, the results have been brilliant.

The immediate operation by the skillful surgeons by whom it was done, and the time that has already elapsed, make it almost certain that there is no danger of peritonitis from the primary soiling of the peritoneum. Peritonitis might possibly arise later from leakage at the site of the repaired wounds in the stomach, either by the wounds being opened by the peristaltic movements of the stomach or by sloughing of the sutures, but this is extremely unlikely, for the same reason that prevented the primary peritonitis.

Perhaps next to peritonitis uremia is most to be

feared, together with the other dangers inseparable from an extensive operation upon a man of the President's age. These dangers are, however, minimized because of the skillful hands in which the President is placed and because of his temperate habits.

An injury to the spine can be ruled out, as it would surely have shown itself before this.

Injury to the kidney would have been shown by blood in the urine, and a retro-peritoneal or free peritoneal hemorrhage. The greatest danger here, aside from a free hemorrhage, is a secondary retro-peritoneal abscess, which would be a serious but not necessarily fatal complication.

Should the bullet be lodged in the muscles of the back it will probably give no trouble; should it do so, however, it can readily be located by the aid of the X-rays and removed.

As long ago as 1822, long before the days of aseptic surgery, there was reported the famous case of Alexis St. Martin, who was shot in the abdomen with a musket ball and received far more extensive lesions than appear to have been inflicted upon President McKinley, and yet under the care of Dr. William Beaumont the patient recovered and lived for many years, although with a gastric fistula.

There are other remote effects of the injury that may possibly interfere with the President's subsequent health, such as contraction of the cicatrices of the wounds in the stomach or adhesions between the stomach and other organs. It is, however, too soon for the discussion of these points.

In summary, the three chief dangers by which the President is threatened are peritonitis, retro-peritoneal abscess, and uremia. The first seems most important, but prompt aseptic surgery has done very much to minimize this. The second, retro-peritoneal abscess, depends on an infection of the final resting place of the bullet and, although very serious, is not necessarily fatal. The third, uremia, depends largely upon the previous state of the patient's kidneys, which is unknown to us.

So, though we cannot deny that the crime of Czolgosz has greatly imperiled the life of the Chief Executive, yet we have strong grounds for the hope that this valued life will be spared to us for many long years to come.

Medical and Sanitary Progress in the Philippine Islands.—It is a pleasure to note the progress being made by the United States Government in the Philippine Islands. As far as medical and sanitary science is concerned the Government seems to be pursuing a most enlightened policy. The same thing can be said of the Philippines that has often been said of Cuba—the advent of the American Government has been an unqualified blessing to both these regions. We do not presume to discuss politics or

policies in these columns, but we do pretend to keep an eye open for all items of medical interest. We are reminded of this subject especially by reading some acts recently passed by the United States Philippine Commission, "by authority of the President of the United States," who now lies sorely stricken by the hand of an anarchist. One of these acts is for the establishment of Government laboratories—chemical, biological, etc.—and the other is for the establishment of a board of health for the islands. Both these acts are on the most liberal and enlightened plan, and contain some features that could well be copied in some of our home cities. Thus the board of health for the Philippine Islands is by law composed almost entirely of duly qualified physicians who have taken doctors' or licentiate's degrees in medicine from reputable medical schools. These members consist of a commissioner of public health, a sanitary engineer, a chief health inspector, and a secretary, all except the engineer being qualified physicians. In addition to these are the superintendent of government laboratories, *ex officio*, and the chief surgeon of the United States Army, and the chief surgeon of the Marine Hospital Service in the Philippines, as well as the president and vice-president of the Association of Physicians in the Philippines, as honorary members. The acts are too voluminous for us to quote in full, but we may say that they are very explicit, and their intent is evidently to keep the administration of these distant islands fully in accord with advanced sanitary science. Our various pessimistic friends and moral statisticians, who are bewailing the cost of "militarism" and "imperialism," might obtain some comfort for themselves if they would keep better track of the real work which their Government is doing for civilization. Of course, it costs money—but perhaps in the end it will pay. Certainly medical science will not suffer from it.

The American Association for the Advancement of Science.—We are pleased to note that at the recent meeting of this Association at Denver a section on Experimental Medicine and Physiology was instituted. It is proper in every sense that medical science should be represented in this representative association of all the sciences. Medicine is more or less closely associated with many of the physical sciences, and it is not difficult to appreciate how mutual advantage may arise from such association in an annual national gathering. We have pointed out before in these columns that for many years the meetings of the British Association, of similar name and objects, have been the occasions of many important contributions to medical science. Moreover, the presidency of the British Association has more than once been conferred upon eminent mem-

bers of the medical profession, notably in recent years upon Sir William Turner and Sir Michael Foster. In the American Association, if we mistake not, medical science has not been quite so conspicuously represented. In this country there are so many purely medical associations that the tendency is, perhaps, for medical scientists to become somewhat too clannish. But we insist that medicine, surgery and hygiene, as among the most important of the physical sciences, should take their places along with the other sciences, in any association which aims to be truly national and representative. We trust that in the future the claims of the profession, to be among the foremost of all the scientists, will be ably maintained in the American Association for the Advancement of Science.

Relative Death Rates of Large Cities.—A bulletin of mortality statistics, issued lately by a Government bureau has attracted some attention, especially in Philadelphia, on account of a somewhat unfavorable showing for this city. The study of such statistics is useful to the sanitarian, but mere annual totals may be misleading. The details should be collected and compared. Unfortunately each city has a more or less special system of classification and arrangement, and it is not possible to pick out of the different reports data of exactly the same class. Some of the salient features may, however, be indicated. For the three cities, New York, Chicago, and Philadelphia, the only cities on the continent having more than one million inhabitants, the latest coincident reports are those for 1898, and that for Philadelphia is below the usual standard. The following figures are compiled as carefully as the official forms permit, and may be regarded as fairly accurate. The deaths in each class are reduced to the basis of one million living persons:

DEATHS PER MILLION.

	New York.	Chicago.	Philadelphia
All Cases,	18,900	15,000	19,000
Phthisis,	2,207	1,610	2,065
Pneumonia,	2,312	1,611	2,000
Suicide,	199	230	132
Cancer,	573	600	536
Old Age,	331	248	770
Measles,	186	37	187
Scarlet Fever,	201	45	90
Diphtheria,	417	415	800
Whooping Cough,	204	137	130
Typhoid Fever,	193	425	450
Bronchitis,	550	666	348
Homicide,	34	51	17
Deaths under 5 years.			
(All Cases.)	7,300	5,400	6,400

It will be seen that Philadelphia has the highest total rate, and high rate in diphtheria, typhoid fever,

and old age. Compared with Chicago the rates for phthisis and pneumonia are also high. The bad water supplies of Chicago and Philadelphia are well indicated in the typhoid rates. On the other hand, the quieter life of Philadelphia, "its slowness" perhaps some might say, is shown in the low figures for homicide and suicide. The Chicago and New York reports give figures for accidents and negligence, but it is not possible to get comparable data from the Philadelphia report.

Dercum's Disease.—We have been much interested in the thesis of Dr. Louis Vitaut on the "*Maladie de Dercum*," a copy of which has recently come to hand. Vitaut's thesis was presented to the Faculty of Medicine of Lyons for the doctorate in medicine, and has just been published in that city. This affection, it may be recalled, was first differentiated by Dr. F. X. Dercum, of Philadelphia, in a patient whom he observed in the nervous wards in the Philadelphia Hospital. Since the appearance of Dercum's original report the disease has slowly gained recognition, until now, as we learn from Vitaut's thesis, it has been described by other observers, not only in America, but also in England, France, Italy, and Germany. Altogether there have been sixteen cases reported, among the first of which was that of Dr. Frederick P. Henry, of this city.

Dercum's disease, or adiposis dolorosa, is characterized by a lipomatosis, either diffused or in tumors; by pain, especially over the nerve trunks; by anesthesia in contiguous territory, and by psychic disturbances. Of accessory symptoms; motor and sympathetic disorders are especially noteworthy. Several types are distinguishable, according as the lipomatosis is nodular or diffused. The causes are found in heredity, alcoholism, and trauma. A nervous mechanism is assigned for the pathogenesis. At autopsy the nerve trunks, the adipose tissue, and the thyroid gland have been found to be the seats of pathological changes. Vitaut asserts that the most reliable treatment has been by the use of thyroid extract. We have ourselves always inclined to regard the affection as allied with the toxemias, which exert their influence especially upon the nerve trunks, and have thought that alcohol would be found an important factor, associated with a gouty diathesis. The success achieved with the thyroid treatment, however, opens up new avenues for speculation on the subject of etiology. We congratulate Dr. Dercum, not on having invented, but on having demonstrated a new affection, which is not inappropriately christened with his name.

Hysteria from an Unusual Cause.—We think that Dr. L. E. Holmes' brief paper, which we publish this week, on some unusual effects of a snake's bite, is worth a special comment. We strongly suspect that the anesthesia and temporary paresis were hysterical in character, just as Dr. Holmes suggests. The cause was peculiarly fitted to excite hysterical symptoms; it had all the elements to induce shock and excessive fright. Of course the victim in such a case does not know at first (and may never, in fact, know except from the ultimate result) whether the offending snake is venomous or not. This great uncertainty, this period of doubt and anxiety, is an admirable preparation for hysterical manifestations. The French have noted the same thing following the bite of a dog. In fact, any cause involving shock or horror is quite capable of exciting some of the hysterical stigmata. A stroke of lightning, or a shock of electricity, has been known to do the same thing. The problem presented by such cases is to distinguish the organic from the purely functional; the material from the psychic. Dr. Holmes' case is a thoroughly illustrative one. It emphasizes in an interesting way how a patient may seem to be most alarmingly injured, from a most alarming cause, when in fact she is simply, unknown to herself, presenting some of the tableaux of the grand neurosis.

Compression in the Treatment of Heart Disease.—The justification for the employment of an apparatus to support the heart from without may be found in the various subjective symptoms which are caused by lesions producing dilatation and hypertrophy of that portion of the organ which is most intimately in contact with the thorax. And it is only in such lesions that such therapy is indicated and will do good. It is a well known fact that an hypertrophied heart causes a distension and strain upon the structures that support it, which in turn not only give rise to the various subjective difficulties, but may also objectively give rise to perceptible alterations in the large vessels. The instinctive impulse of patients with heart disease to press their hand over the precordium for relief has suggested to many investigators an artificial support. As Benedict has shown, the lung during inspiration not only presents itself on the left between the surface of the heart and the throat above, but also is, present on the left side between the apex of the heart and the diaphragm below. It follows, therefore, that an hypertrophied heart will be benefited by support the more it can be prevented from exerting injurious pressure upon its neighboring structures. Various devices have been constructed under the

direction of Abéc Hellendahl and Mendelsohn. The latest device is reported by Professor Martin Mendelsohn, of Berlin, the description of which will be found in the *Berliner klinische Wochenschrift*, August 26, 1901. It appears that such treatment, based upon well authenticated physical conditions, may well supplant in many cases the administration of drugs.

The Scribbling Paranoiac.—In his chapter on monomania, Spitzka, in his inimitable style, relates the case of a delusional lunatic who wrote a treatise in defense of polygamy, sustaining his position with voluminous quotations from ecclesiastical authors. The case is a type of its kind, although the patient, as may be judged from the subject of his treatise, was evidently a sexual pervert—an obsession which cannot be charged against all the insane. Some epochs are especially afflicted with these scribbling paranoiacs. Political and religious excitement breeds them. Pseudo-scientific zeal often possesses them. Ethical problems appeal to them. Where the facilities for getting into print are great, the literary lunatic is quick to avail himself of the chance. Unfortunately in some countries the opportunities are too easily afforded him; consequently he bursts upon the public at most unexpected times and in most inappropriate places. Such a person uses the pen or the hatchet with equal readiness. Mrs. Carrie Nation, who is also a living representative of this class, uses the hatchet.

The characteristics of the scribbling paranoiac are intense egotism and unceasing activity, associated with a passion for reform. The man to whom Spitzka refers, wished to reform the church and bored the ecclesiastical authorities with his mad schemes. Such a man has no sense of humor. The ridiculousness and impracticability of his plans, especially as emanating from such an individual as himself, never occur to his own mind in the remotest way. His writings are usually without consistency; without co-ordination; without knowledge or judgment. He is incapable of sustained effort. Real science wearies him. Philosophy and literature are closed books to him. He is immersed in the lucubrations of his own disordered intelligence.

This is one of the most extraordinary chapters in the history of psychiatry. The author of *Pilgrim's Progress* (a disordered fantasy) was the victim of insane hallucinations. The *Crusades* (a pandemic frenzy) were started by a preaching monomaniac named Peter the Hermit. We have personal knowledge of an incarcerated lunatic who is a frequent contributor to the poet's corner in one of Philadelphia's largest daily newspapers. In the asylums it is not uncommon for the attendants to collect whole

reams of manuscript, which perish for the want merely of an editor to publish them. But the most genial example of his class (although he was a reformer rather than a scribbler) was Don Quixote, who charged upon a windmill or a flock of sheep with the valor of a paladin. Finally, we all recall the Hindoo reformer, Ram Das, of whom Carlyle tells us that he had fire enough in his belly to burn up all the sins of mankind.

Mortality from Gunshot Wounds of the Abdomen.—Apropos of the President's case we submit the following:

Gunshot wounds of the stomach are usually classed with intestinal bullet wounds.

Alcock (quoted by Henry Morris in the *Internat. Ency. Surgery*, Vol. V, p. 512) gives one case of recovery out of 3,000 gunshot wounds of the stomach. This was before the days of modern surgery.

Of 110 sections for gunshot wounds of the abdomen, 62 per cent. died.—T. S. Morton (*Jour. Am. Med. Ass'n*, Jan. 4, 1900).

Of 253 cases of gunshot wounds of the abdomen operated upon, 52 per cent. died.—H. H. Grant, *Philadelphia Medical Journal*, July 22, 1899.

Of 3,475 penetrating abdominal wounds during the Civil War, 3,031, or 87.2 per cent., died. During 1898 and 1899, 81, or 70 per cent., of 116 cases died. Of 10 operated upon 9 were fatal.

Report of Surgeon General, June 30, 1900.

Correspondence.

THE CIGARETTE.

By ALEXANDER R. BECKER, M. D., of Seattle, Wash.
To the Editor of the *Philadelphia Medical Journal*:

There are few subjects upon which so much ignorant abuse has been expended during the recent centuries as Tobacco, while its lovers have gone on enjoying it in calm comfort and content and with only a mild contempt for its detractors. Most of this has died out during the recent decades, excepting on the sub-subject of Cigarettes, which have been made the butt for every sort of ridicule and vilification that prejudice and ignorance could devise, and to which but very few sensible men have taken the trouble to reply. This latter course may be well enough for a busy people so long as the sinners are to be found only in the daily press—whose penny-a-liners are pardoned much in view of their efforts to gain their daily bread, and in the State Legislatures—whose aberrations are far too patiently borne by our long-suffering people. But when physicians write to first-class medical journals with the same combined ignorance and superciliousness, and attempt to instruct others from the basis of one utterly inconclusive case it does seem time to say a few words from a scientific standpoint.

First, then, as to Tobacco—of which it is particularly true to say, in the words of the old proverb: "What is one man's meat is another man's poison"—while it is positively true that there is no article of general consumption that has brought so much of soothing comfort to the ordinary healthy and normal man, the world over, and with so little of harm, it is also true that it is harmful to an infinitesimal minority—who should leave it alone, and positively poisonous to boys and youths—to whom it should be utterly prohibited, both by parental authority and by law (although the former should be ashamed to require the assistance of the latter). But neither one of these limitations

constitutes a point against tobacco, but only against those classes who cannot use it.

All these adverse writers lay dreadful stress upon nicotine and nicotism—apparently in ignorance of the fact that the chemists have isolated more than twenty "products of combustion" and are far from unanimous in estimating their respective values and powers. But there is one practical result of very real importance from their investigations—that these "products" become more and more concentrated and powerful by being drawn through more tobacco confined in tubes—such as cigars and pipes, while the object should be to secure the free and rapid combustion of comparatively small quantities at a time. The Japanese accomplish this with their tiny pipes, which are about the size of half a small lady's thimble and flaring at that. The Turks do so less perfectly by their shallow and flaring bowls—of both narghileh and chibouque. While the German concentrates everything (in his generally wretched tobacco) in his deep pipebowl of heathholding porcelain. On the other hand, the most fastidious cigar-smokers use the smaller sizes only and then smoke but half of each. And now we come to the consideration of cigarettes—the daintiest and least harmful of all, provided the components be of the best, because they contain the minimum of tobacco to be soaked with the products of combustion before being itself consumed; for the average cigarette is less than three inches long, which leaves only two inches to be smoked—less than gr. x in even a fat, gold-tipped "Milo."

Who have been the cigarette-smokers? From the Latin colonies of this Western hemisphere the habit went to Spain and Portugal; from Asia Minor it extended through all northern Africa and Turkey and to Russia; it was carried to France by the troops returning from the Algerian conquest, and to England by those returning from the Crimea; and yet in not one of those countries has there ever been any hue and cry against it, nor have any cranks—still less physicians—arisen to call it cursed. But perhaps there has been ground for that difference—for in those "effete" countries the efforts of manufacturers, and of the governments—so far as they concerned themselves, lay in providing good and pure tobaccos and improved and unirritating wrappers; while some of the rascally manufacturers of this country vied with each other in efforts to produce the cheapest cigarettes, on which they could make enormous profits, and then dosed them with narcotic solutions—of opium, cannabis indica, cocaine—so that the smokers, once habituated, should find no comfort in other brands. The individual doses were undoubtedly very small, but quite sufficient, when frequently repeated, to form and confirm the pernicious habit, as shown by the "ashy complexion," the hebetude, and progressive mental and physical decay; conditions *never* resulting from tobacco smoke; but the unthinking public and unthinking physicians lay all the blame upon "the Cigarette," without ever suspecting the Mephisto in the little roll.

It is not strange that many people should suppose that the inhalation of smoke must be irritating to the mucous membranes of the air-passages. In fact, it is apt to be so at first, and is persistently so in some people—who should therefore avoid it; but we are emphatically creatures of habit and our mucous membranes are possessed of a very wide adaptability; and the fact that it is not injurious in that way is amply proved by the results—for cigarette smokers are not only *not* more liable to throat and lung diseases than others, but often find their air passages *less* sensitive to atmospheric changes than before.

Conclusions:—Tobacco in *all* forms ought to be absolutely prohibited to boys of less than 18 or 20; (2) Adulterations of tobacco ought to be rigidly ferreted out and punished under laws of Congress; (3) There is a small minority of men to whom tobacco is more or less harmful, and they should refrain from it—but without attempting to stretch or squeeze all the rest of mankind into their Procrustean limit. There are those who have idiosyncrasies—who cannot take opium or quinine or belladonna without harm, in whom shellfish cause urticaria, or a plate of strawberries will produce as sharp an attack of gout as a bottle of Burgundy. But shall any of these small minorities rule the great normal majority? Not in this free country—although it is here, so far more than elsewhere, that they attempt it in so many directions.

And to those physicians who speak and write unadvisedly I would only say: "Brethren, study and still study, so that you may teach out of knowledge and not prejudice."

"CUBAN ITCH" AND IMMUNITY.

By HORACE S. JONES, M. D., of Kansas City, Mo.,

That we inherit physical and mental characteristics, is an undeniable fact, though the mechanism is not understood. We also know that the tissue cells can inherit a tendency to disease, a retrograde metamorphosis; then by the same law it is not unreasonable to suppose that immunity to disease can likewise be transmitted.

Certain contagious diseases, because they effect some unknown permanent change in the entire body, render it afterward immune to the same disease; now by the introduction into the economy of germs of any of these diseases we accomplish the same result as the disease *per se*; witness the result of vaccination. The immunity resulting, will, by its effect on succeeding generations, tend, by inheritance alone, to produce immunity. "Cuban Itch" I believe to be the effect of the above mentioned causes, it being nothing more than mild smallpox. Thus vaccination and inherited immunity have so modified one contagious disease as to almost render it unrecognizable. When vaccination becomes a universal practice, smallpox will be no more.

CAUSES OF INTESTINAL OBSTRUCTION.

By A. L. BENEDICT, M. D., of Buffalo,

The writer contemplates publishing an article dealing with intestinal obstruction from the standpoint of internal medicine. In order to make the study as complete as possible, the accompanying table of causes is printed in advance, to elicit criticism. The writer will be greatly obliged for suggestions of additional causes, of subdivisions under general causes and for case-reports illustrating rare forms of obstruction. Due credit will be given for any such information and material.

1. Causes inside the bowel.
 - Fecal accumulation.
 - A. Complete obstruction.
 - B. Bowel pervious to liquids.
 - Gall stones.
 - Enteroliths.
 - Foreign bodies.
 - A. From food.
 - B. Hair balls.
 - C. Parasites.
 - D. Foreign bodies proper.
2. Causes outside the bowel.
 - Peritoneal bands.
 - Aperture in omentum, mesentery, etc.
 - Entanglement with long appendix, diverticulum, persistent vitelline duct, etc.
 - Strangulated hernia, external or internal.
 - Pressure of tumors.
 - Rotary dilatation following pressure of uterus, pelvic lymph-nodes, vaginal tumors, etc., on rectum.
3. Causes affecting bowel itself.
 - Volvulus.
 - Stricture, cancerous, syphilitic, tubercular, or following typhoid, traumatic and other ulcers.
 - Contractures due to matting together of intestinal coils.
 - Intussusception.
 - Nervous contraction.
 - A. Tonic.
 - B. Spasmodic (N. O. Werder.)
 - Tumors of bowel, including polypus and hemorrhoids of rectum.

A Rare Congenital Affection of the Hip-Joint.—In the *Centralblatt fuer Chirurgie*, (June 8, 1901, No. 23), K. Trantzscher describes an anomaly seen in a dead-born infant, breech presentation, the mother being a primipara, aged 31. Extension of the legs upon both sides was impossible, the rigidity being most marked, however, on the right. There was slight lordosis of the lumbar vertebrae, but no changes of the bones. The condition resembled coxa vara. Dissection showed a shortening of the anterior wall of the capsule of the hip-joint, the iliofemoral ligament. Trantzscher believes that the cause of the condition is atrophy from inactivity, due to the cramped breech position. [M. O.]

American News and Notes.**PHILADELPHIA, PENNSYLVANIA, ETC.**

The Craig Colony for Epileptics, which now has 620 patients, will be able to accommodate 120 more when the four buildings, now being built, are completed.

Immigrants Inspected at the Port of Philadelphia.—Total number of immigrants inspected 1,175; number passed, 1,144; number certified for deportation on account of dangerous contagious or loathsome diseases, or for other physical causes, 31.

Philadelphia County Medical Society.—The North Branch of the Philadelphia County Medical Society will hold its first meeting at S. E. corner of Broad street and Columbia avenue, on Thursday evening, September 19th, at 9 o'clock. Addresses will be made by Drs. John B. Roberts, Judson Daland, Henry Beates, A. B. Hirsh, Albert M. Eaton and others. All physicians eligible for membership to the County Society are welcomed to attend the meetings.

The Reading Railway Company has opened an emergency hospital at Tamaqua, Pa.

Disease in Philadelphia.—Following is the report of the Health Officer for typhoid fever and smallpox in Philadelphia during the month of August, showing 1102 cases. Typhoid fever heads the list with 558 cases, the large number being attributed in part to the pollution of the Schuylkill from its watershed up the State by surface washings from the heavy rains. During the month 52 cases of smallpox were reported in the city. The disease is pronounced to be of a mild type. Scarlet fever caused the illness of 172 persons, 162 cases of diphtheria and 158 of consumption were reported.

For a Psycho-Physical Laboratory.—We are requested to announce that the County Medical Societies, as well as the State Medical Association of Pennsylvania have been asked to consider the resolution for a Psycho-Physical Laboratory at Washington for medico-scientific and sociological purposes. The resolution reads as follows: That we are in favor of the establishment of a Psycho-Physical Laboratory in the Department of the Interior at Washington for the practical and abnormal or pathological data, especially as found in institutions for the criminal pauper and defective classes and in hospitals and also as may be observed in schools and other institutions.

The Will of John D. Lankenau.—The principal beneficiaries are the German Hospital and the Mary J. Drexel Home, each of which it is stated would receive as residuary legatees the sum of \$600,000. The Pennsylvania Society for the Relief of Distressed Germans is bequeathed \$5000, and a like amount is given to the Lutheran Orphan Asylum. With the exception of a number of family pictures, the bulk of Mr. Lankenau's splendid collection of paintings will go to Drexel Institute. This collection is valued at \$150,000. The will provides that the Mary J. Drexel Home and the German Hospital, the principal beneficiaries, shall be limited as far as possible to the interest on the sums which are bequeathed to them. Authority to make expenditures in excess of the income is invested in the executors and an advisory committee, consisting of Edward T. Stotesbury, George C. Thomas and Thomas W. Paul, Jr.

Wills' Hospital Ophthalmic Society.—Meeting held in Philadelphia, April 22, 1901.—Dr. William Thomson in the Chair. **Suppurative Chorioiditis.** Dr. Charles A. Oliver exhibited a case of suppurative chorioiditis, the result of an infective traumatism in a three year old boy. The conditions were typical, the brunt of the uveal disturbance having been exerted upon the posterior half of the tract. It was his intention to remove the eyeball, which was blind, in order to make a series of bacteriological and histological studies as to the character of the infection and the pathological conditions of the inflamed parts.

Dr. P. N. K. Schwenk gave the details of a similar case in which the eye had been struck with a piece of wood when the patient was two years of age.

Vascular Keratitis.—Dr. McCluney Radcliffe showed an example of vascular keratitis in a nineteen year old man who had been under treatment for a long period of time. There was not any history of syphilis nor were there any

evidences of granular disease. In spite of the most careful hygiene and the best therapy, the conditions had increased until at the time of the meeting there was a large deeply saturated ulcer of several days standing situated at the site of the initial lesion.

Dr. Frank Fisher gave a most excellent example of a chronically recurrent case in a forty-five year old Negro. The corneal ulcer was crescentic and probably infectious in type.

Drs. Thomson and Oliver laid emphasis on the general treatment of such cases and spoke of the absolute necessity of determining the etiological factor in every instance. Dr. William L. Zull stated that his experience had taught him that calomel applied locally was an extremely efficient remedy. He had seen the condition shown in the present case appear as the result of excessive ingestion of sugar. Dr. Schwenk made some remarks upon the value of harmless anodynes in producing many hours of continuous sleep, thus permitting the parts to obtain undisturbed rest for long periods of time.

Gumma of the Iris.—Dr. Thomson presented a case of gumma of the iris in which in spite of negative history the symptoms rapidly subsided under specific medication, giving as it were a therapeutic proof of the diagnosis. On admission there was a moderate hypopyon and a small-sized vascular growth at the root of the iris over which the iris-tissue seemed destroyed and the adjacent sclera quite prominent. At the time of the presentation of the case, both the swelling and the hypopyon had disappeared, the eye being comfortable and quiet in spite of quite a number of posterior synechia. Vision had improved from one two-hundredths to one-tenth of normal. Dr. Thomson showed a second case which was practically similar to the other. In this one there was a distinct history of syphilis. Both occurred in Negro subjects. Dr. Oliver stated that in his experience most iris gummata appeared either at the minor or the major vascular circle. With the latter there was almost always an associated ciliary involvement, followed in marked cases by more deeply seated uveal trouble. In this type of cases vision, while not greatly affected at first, often temporarily failed to a marked degree owing to a discharge of translucent gummy material into the intraocular spaces. He considered this symptom as a good sign for rapid convalescence. In a few cases he had had the good fortune to secure such a restitution of the transparency of the media as to distinctly see the eyeground and to permanently obtain practically normal vision. In these cases there were the characteristic pictures of neuro-retinitis consecutive to uveitis. Leukocytic hypopyon he had found most frequently marked in cases in which inflammatory reaction had been extreme and in young subjects. His experience showed that the disease was extremely prevalent among the Negroes. In every case in which he had been enabled to make after-studies he had found the involved portion of the iris to be friable, discolored and thinned. His best therapeutic results had been obtained by the free use of mercury by inunctions, taking care to prevent any toxic effects. Dr. Thomson had found the plan of having the patient rub the mercury on the skin of the dorsal surface of the foot, with the wearing of a covering stocking, to be the most rapid and the most efficacious method of employment of the drug.

Dinner in Honor of Dr. John S. Miller.—Professional friends of Dr. John S. Miller, of Denver, Col., who was formerly one of the demonstrators of anatomy in the Jefferson Medical College and surgeon to St. Joseph's Hospital, in this city, tendered him a dinner. Professor Francis X. Dercum, M. D., of Jefferson Medical College, presided and acted as toastmaster, and among the toasts was a very hearty one—"To the Recovery of President McKinley." John S. Miller, A. M., M. D., was born in Philadelphia, Pa., in 1856. He was educated at the public schools, and was a law student from 1875 to 1879. He was graduated from the Jefferson Medical College in 1882 with high honors. He was elected interne to the German Hospital, and received an honorary degree of Master of Arts from La Salle College in 1886. He was assistant in the Surgical Clinic at the Jefferson Medical College, and one of the demonstrators of anatomy for ten years. In 1888 he was made surgeon to St. Joseph's Hospital, which position he held until 1899. Dr. Miller was the first Philadelphia surgeon to reach Johnstown after the great catastrophe. He opened a hospital tent for the treatment of sick and injured workmen engaged in recovering bodies and the removal of

wreckage. In 1900 Dr. Miller removed to Denver, Colorado.

Vital Statistics for Philadelphia for the week ending September 7, 1901:

Total mortality	399	Cases.	Deaths.
Inflammation of the bladder 1.			
braia 4, bronchi 2, heart 1, kidneys 19, liver 2, lungs 14, peritoneum 2, pleura 2, stomach and bowels 34, appendix 2, spine 2.			88
Marasmus 32, inanition 17, debility 2			51
Tuberculosis of the lungs			42
Apoplexy 13, paralysis 3			15
Heart-disease of 22, dropsy of 1.			
neuralgia of 1			21
Uremia 13, Bright's disease 4, diabetes 2			19
Carcinoma of the liver 3, breast 2, stomach 4, uterus 5, rectum 1.			15
Convulsions, puerperal			3
Diphtheria	42		4
Brain-disease of 1, softening of 2.			3
Typhoid fever	96		12
Old age			7
Asthma 1, burns and scalds 3, casualties 13, child birth 1, cholera infantum 16, cholera morbus 1, cirrhosis of the liver 1, cyanosis 1, diarrhea 2, drowned 17, dysentery 1, epilepsy 2, erysipelas 1, fever, malarial 1, fracture of femur 1, hemorrhage from stomach 1, hernia 1, homicide 1, measles 2, obstruction of the bowels 4, rheumatism 2, septicemia 1, smallpox 4, suffocation 2, suicide 9, sunstroke 1, tumor, uterus 1, unknown coroner case 1, whooping cough 12, wounds, gunshot 2			196

NEW JERSEY.

A Well of Sulphuric Acid.—A flowing well of sulphuric acid has been discovered in Vineland, N. J. The phenomenon was first noted after a severe electric storm during which four houses in Vineland were struck within fifteen minutes. After the storm the contents of a well were found to be acid, and a chemical analysis of the water showed the presence of sulphuric acid. The apparently accepted theory is that the lightning struck a sulphur deposit in the earth, which, upon being ignited, liberated sulphur dioxide; this in turn uniting with the moisture in the earth, formed sulphurous acid, which, upon oxidation gave rise to the sulphuric acid. It is not believed that sufficient sulphuric acid will be obtained from the well to be of commercial value.

Medical Diploma Mill Exterminated.—About a month ago Governor Voorhees was informed that the Central University of Medicine and Science, managed by John W. Norton Smith at Jersey City, was offering to sell medical diplomas for \$10 each. Now the counsel for Smith submitted to Mr. Vickers a proposition that Smith would consent to forfeit his charter on condition that no further action should be taken. This was agreed to, and Smith then surrendered himself. He was taken before Justice McCormick and gave bail in \$200, nominally to await the action of the Grand Jury on a charge of obtaining money on false pretences, but really as security that he will abide by his agreement.

NEW YORK.

Monument to Dr. Alexander J. C. Skene.—A monument will be erected in Brooklyn, N. Y., to the memory of the renowned gynecologist, Dr. Alexander J. C. Skene, at a cost of \$25,000.

Tenement Houses in Brooklyn.—In Brooklyn all houses occupied by three or more families must be registered as tenement houses. Failure to register is punishable by a fine of \$50. This regulation goes into effect on September 6.

Omega Upsilon Phi Fraternity (Medical).—The Fifth Annual Convention of the Omega Upsilon Phi Fraternity

(Medical) was held August 29 and 30, at Buffalo, N. Y. Dr. Edward M. Thompson, of New York City, was elected President; Dr. Dean O. Thompson, of Hornellsville, New York, Secretary, and Dr. George H. Minard, of Lockport, N. Y., Treasurer. A banquet was held at the Hotel Genevieve, Buffalo, on the evening of the 29th, and was a great success. The next convention will be held in New York City during September of next year.

Major William Kendall and Captain Edward L. Munson, of the Medical Department of the Army, have been ordered to represent that department at the annual meeting of the American Public Health Association, to be held at Buffalo, N. Y., from the 16th to the 20th instant.

NEW ENGLAND.

Dr. Gates B. Bullard, a physician of high standing, died September 4, 1901, at St. Johnsbury, Vt., aged 72 years. He was surgeon of the Fifteenth Vermont Regiment in the Civil War, and later Surgeon General of Vermont.

Dr. John J. Wagner, Greenwich, Conn., was injured in a runaway accident August 25, breaking his leg.

A New Building for Newport Hospital.—Mrs. Cornelius Vanderbilt will give to the Newport Hospital a new building as a memorial of Cornelius Vanderbilt. The building will enable the hospital to provide at a moderate cost private rooms for the poorer class of patients who may require such accommodation. One story will be used for this purpose and one for the out-patient department, which has been very successfully operated, as far as accommodations would permit, for some time. The building will be constructed of the same materials and on the same general plan as the buildings already in existence, except that it will be a two instead of a one-story structure.

WESTERN STATES.

The Rocky Mountain Inter-State Medical Association met in Denver September 3 and 4. This was its third annual scientific meeting. It has a membership of 170, of whom 50 were in attendance, beside a number of physicians who were not members. Papers were read upon: The Retinal Lesions of Chronic Interstitial Nephritis and Their Significance, by Edward Jackson; Carcinoma of the Breast, by D. A. Richardson; The Medico-Legal Aspect of Amnesia, with Report of Cases, by S. D. Hopkins; Resection of the Middle and Superior Ganglia of the Cervical Sympathetic for Acute Glaucoma, by Melville Black; Reports of Cases of Acute Hemorrhagic Pancreatitis, by Leonard Freeman and O. J. Pfeiffer; Acute Pancreatitis, by Carrol E. Edson; Methods and Results in Operations for Cancer of the Breast, by Chas. A. Powers; Economic Medicine, by G. P. Johnston; Diagnostic Value and Examination of Feces, by C. D. Spivak; A Report of Seventy Cases of Lobar Pneumonia, by J. N. Hall; The Chemical Treatment of Wounds, by R. Harvey Reed; How to do Clean Surgery at Small Cost, by J. S. Perkins; The Function of the Appendix, by E. P. Hershey; Report of Case of Rapid Respiration (143 per minute) in Fatal Organic Disease of the Brain, by J. T. Eskridge; Report of Case of Removal of the Stomach for Cancerous Growth, by E. S. Wright; An Operation for Spina Bifida with Report of a Case, by Leonard Freeman; So-called Mountain-Fever, by W. W. Wooding; Report of Two Unusual Cases of Multiple Neuritis in Children, E. Delehanty; Conservative Surgery of the Ovaries and Tubes, by W. W. Grant; Report of Surgical Cases, by I. B. Perkins. A number of papers were read by title, and the retiring president, C. K. Fleming, of Denver, read his address. For the ensuing year R. Harvey Reed, of Rock Springs, Wyoming, was chosen president, and Donald Campbell, of Butte, Montana, and W. R. Pike, of Provo, Utah, vice-presidents. The next annual meeting will be held at Cheyenne, Wyoming.

The American Pharmaceutical Association will open its forty-ninth annual meeting at the Southern Hotel, St. Louis, September 16 to 21, and continue its sessions daily throughout the week. H. M. Whelpley, of St. Louis, is secretary.

Embalmers Must Be Examined.—By an order of the State Board of Health embalmers in Michigan will be required to pass an examination and receive a license before they are permitted to practice their profession.

A Monument to Dr. William Beaumont.—A monument is being erected on the grounds of the old Government fort on

Mackinac Island to Dr. William Beaumont. Dr. Beaumont was born in Connecticut, and was known as one of the greatest investigators in the profession. He was appointed surgeon's mate, Sixteenth Connecticut Infantry, December 2, 1812, and later to the Eighth.

Dr. William L. Carls, of Hebron, Nebraska, has been appointed assistant physician of the Hospital for the Chronic Insane at Hastings, Nebraska, vice Dr. Woodward, resigned, and Dr. Alma J. Chapman, of Hastings, succeeds Dr. Ewing, resigned.

Prof. Paul C. Freer of the general chemical laboratory of the University of Michigan has gone to the Philippines to take charge of a branch of the Department of Health there. He has received a year's leave of absence from the university.

SOUTHERN STATES.

Dr. L. Ashton, formerly of Fredericksburg, but for some years a resident of Dallas, Texas, has been elected to the chair of theory and practice of medicine at Trinity University, of that State.

The Cocaine Habit in Roanoke, Va.—The cocaine habit is growing to such proportions in Roanoke that legislation against the sale of the drug is contemplated, although there are doubts as to the legality of such action. It is said that there are fully 500 confirmed cocaine fiends in the city.

Disease in Virginia Diminishing.—The efforts of the State Board of Health to eradicate small-pox from Virginia have been rewarded. Recent reports show that only a few cases now exist and they are restricted to five counties. Reports show that there is very little sickness in the State, the most prevailing disease being enteric fever.

MISCELLANY.

PRESIDENT McKINLEY'S CONDITION.
AT THE TIME OF GOING TO PRESS WE ARE DELIGHTED TO BE ABLE TO STATE THAT THE CONDITION OF THE PRESIDENT IS INDICATIVE OF HIS RECOVERY. THE SURGICAL ASPECT OF THE CASE CALLS FOR THE GREATEST PRAISE FOR THE PROMPTNESS AND EFFICIENCY WITH WHICH MODERN SURGICAL ART WAS PUT INTO PRACTICE. PROMINENT SURGEONS ARE ALMOST UNANIMOUS IN DECLARING THAT THE PROMPTNESS WITH WHICH THE ABDOMEN WAS OPENED, AND THE RIGID ASEPSIS WHICH WAS OBSERVED ARE RESPONSIBLE FOR THE PRESIDENT'S CONVALESCENCE.

Dental Surgeons for the Army.—Since the commencement of the great Boer War demands of a persistent character have come from the army in the field for dental men to look after the men's teeth. Toothache, we all know, is persistent, and if any pain takes all work out of a man it is that of an aching tooth. From this cause an immense number have been made absolutely useless in South Africa, and the officers of the Royal Army Medical Corps have not been able to cope with the trouble. And how could they, for they get no dental education beyond possibly teeth extraction, and every aching tooth does not demand removal. So pertinaciously has this demand been made that it seems likely to receive attention in the near future. The same complaint reached the Government of the United States from the army in Cuba and the Philippines, and, as our American cousins lead the world in dentistry, they have already acted in the matter. Sixteen dental surgeons have been named for the United States Army, and more will follow. They have not been commissioned as officers, though we see no reason why they should not be, but have entered into a three years' contract with the Surgeon General, which may be renewed.

During their service they wear the uniform of a First Lieutenant—save that the braid on the shoulder-straps is silver instead of gold.—*Ex.*

Obituary.—Dr. George W. Wells, at Richmond Hills, Long Island, September 2, aged 58 years—Dr. Gustavus Schiff, at San Francisco, Cal., September 2, 1901, aged 78 years—Dr. Gates B. Bullard, at St. Johnsbury, Vt., September 4, 1901, aged 72 years—Dr. Sydney R. Burnap, at Windsor Locks, Conn., September 3, 1901, aged 68 years—Dr. Hudson J. Pulver, at Torrington, Conn., September 3, 1901, aged 42 years—Dr. Dursulla G. Barlow-Cook, at Wilmington, Del., September 9, 1901, aged 30 years—Dr. E. P. Duval, at Annapolis, Md., September 5, 1901, aged 70 years—Dr. Jerry Burwell, at New Hartford, Conn., September 4, 1901, aged 81 years—Dr. George Lewis Staley, Jr., at Baltimore, Md., September 9, 1901, aged 44 years—Dr. Louis C. Berkemeyer, at Allentown, Pa., September 8, aged 61 years.

China is Plague-Stricken.—The Marine Hospital Service continues the publication of letters from missionaries and others in China describing the progress of the plague. Rev. Jacob Spelcher, Baptist missionary, writing from Kit Yang, says: "The plague made its first appearance at Swatow about seven years ago, and has since then spread in all directions along the coast and inland. Three years ago, in the large city of Chan Yang, 10 miles south of Swatow, it is said that over 20,000 persons died. Many villages between Canton and Lio, 70 miles inland from Swatow, have lost one-third to one-half of their inhabitants. In this benighted country nothing is done and the plague will have its run for years. I have received word that the district city of Hui Lal, about 35 miles south of Kit Yang, has had an awful visitation this year. Only one-fourth of the people are still in the city, the others having died or fled. This city was in the line of the 'trail.' Thus far the plague has gotten only 70 miles inland, so far as I can learn."

Invulnerable.—A peculiar case of head-injury is reported to *Texas Medical Gazette*, by Dr. Frank M. Ross. The patient was insane and had made several attempts on his life. In the last desperate effort to end his existence he tried to force a shoemaker's awl into his head, but it was stopped by the bone. He then held the awl in his hand and ran against a brick wall, driving it into his brain up to the handle, which broke off and fell to the floor. The instrument went straight into the frontal lobe. He was unconscious for a few hours and then consciousness returned. About a week later he began to have fever, which kept him in bed for six weeks. After this time he greatly improved and was able to go about his business. His mental trouble returned, and he insisted on having the awl taken out. An operation was performed.

Official List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the U. S. Marine Hospital Service for the 7 days ended September 5, 1901.

- J. O. CORB, passed assistant surgeon, granted 10 days extension of leave of absence—August 30, 1901.
RUPERT BLUE, passed assistant surgeon, granted leave of absence for 10 days from September 2, 1901—September 3, 1901.
J. H. OAKLEY, passed assistant surgeon, granted leave of absence for two months from September 17, 1901—August 30, 1901.
H. C. RUSSELL, assistant surgeon, to proceed to Cleveland, Ohio, and assume temporary command of service during absence of Surgeon W. J. Pettus—August 30, 1901.
H. B. PARKER, assistant surgeon, to proceed to Amite City and Abite Springs, Louisiana, for special temporary duty—August 31, 1901.
M. K. GWYN, assistant surgeon, granted leave of absence for 1 day—August 30, 1901.
B. S. WARREN, assistant surgeon, granted leave of absence for 14 days from September 14, 1901—September 5, 1901.
P. N. BARNESBY, acting assistant surgeon, granted leave of absence for 1 month from September 1, 1901—August 30, 1901.
R. E. EBERSOLE, acting assistant surgeon, granted leave of absence for 7 days from September 3, 1901—Paragraph 181, Regulations, M. H. S.

Changes in the Medical Corps of the Navy. For week ending September 7th, 1901.

- ASSISTANT SURGEON E. THOMPSON, detached from the Solace and ordered home to wait orders—Aug. 31.
MEDICAL DIRECTOR E. S. BOGERT, retired, detached from the Boston Navy Yard, September 5, and ordered home—Sept. 4.
SURGEON I. W. KITE, detached from the Monterey, upon reporting of relief, and ordered home and to wait orders—Sept. 4.

- SURGEON V. C. B. MEANS, detached from the marine recruiting rendezvous, September 2, and ordered to the Monterey as relief of Surgeon I. W. Kite, sailing from San Francisco, Cal., by army transport about October 1—Sept. 4.
SURGEON G. T. SMITH, ordered to the Amphitrite as relief of Surgeon J. M. Edgar—Sept. 4.
SURGEON J. M. EDGAR, detached from the Amphitrite, upon reporting for relief, and ordered home and to wait orders—Sept. 4.
ASSISTANT SURGEON E. O. HUNTINGTON, ordered to the Naval Hospital, New York—Sept. 4.
ASSISTANT SURGEON J. F. MURPHY, detached from the Naval Academy, upon reporting of relief, and ordered to the Indiana—Sept. 4.
ASSISTANT SURGEON T. M. GARTON, detached from the Indiana, and ordered to the Naval Academy as relief of Assistant Surgeon J. F. Murphy—Sept. 4.
MEDICAL DIRECTOR C. F. WINSLOW, ordered to the naval recruiting rendezvous, Boston, Mass., October 1—Sept. 5.
SURGEON C. J. DECKER, ordered to the marine recruiting rendezvous, San Francisco, Cal., Sept. 25, as relief of Surgeon V. C. B. Means—Sept. 5.
ASSISTANT SURGEON P. E. McDONNOLD, detached from the Naval Museum of Hygiene, Washington, D. C., Sept. 9, and ordered to the Constellation as relief of Assistant Surgeon C. A. Crawford—Sept. 5.
ASSISTANT SURGEON C. A. CRAWFORD, detached from the Constellation, upon reporting of relief, and ordered to the Naval Hospital, Chelsea, Mass., as relief of Assistant Surgeon R. R. Richardson—Sept. 5.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended September 7, 1901.

SMALLPOX—United States.

			Cases.	Deaths.
CALIFORNIA:	Los Angeles	Aug. 17-24	1	
	San Francisco	Aug. 13-24	2	
KANSAS:	Wichita	Aug. 24-31	1	
LOUISIANA:	New Orleans	Aug. 24-31	1	
MASSACHUSETTS:	Boston	Aug. 24-31	6	
MINNESOTA:	Minneapolis	Aug. 17-24	5	
NEBRASKA:	Omaha	Aug. 24-31	2	
	South Omaha	Aug. 23-30	3	
NEW JERSEY:	Newark	Aug. 24-31	5	3
NEW YORK:	New York	Aug. 17-31	37	12
PENNSYLVANIA:	Philadelphia	Aug. 24-31	31	2
UTAH:	Salt Lake City	Aug. 19-24	2	
WEST VIRGINIA:	Wheeling	Aug. 18-31	1	

SMALLPOX—Foreign.

AUSTRIA:	Prague	Aug. 10-17	1	
BELGIUM:	Antwerp	Aug. 3-10	1	
BRAZIL:	Rio de Janeiro	July 28-Aug. 4	42

	Calcutta	July 27-Aug. 3	11	

GREAT BRITAIN.

Surgeon-General W. Taylor, M. D., C. B., who has recently been appointed to the Headquarters Staff, in London, has now been appointed an honorary physician to the King.

To Investigate Dr. Koch's Theory.—King Edward has appointed a commission to investigate Prof. Koch's theory regarding the reciprocal non-transmissibility of bovine and human tuberculosis. The commission, which has been granted fullest authority and facilities and which has been urged to make a prompt report, consists of Sir Michael Foster, secretary of the Royal Society; Dr. Sims Woolhead, professor of pathology, Cambridge University; Dr. Harris Cox Martin, Prof. J. McFadyean and Prof. R. W. Boyce.

Enteric Fever in Wales.—A serious outbreak of enteric fever has occurred in Wales at Ebbwale. Several deaths have resulted. There is no isolation hospital, and medical men are experiencing much difficulty in treating the patients.

CONTINENTAL EUROPE.

Lead Poisoning in France.—French painters at Regnoble have gone on strikes on account of the great prevalence of lead poisoning. They demand the employment of zinc oxide instead of lead.

Professor Czerny of the University of Heidelberg, will shortly make an extensive tour of the United States, which will extend at least as far west as St. Louis.

German Orthopedic Society.—At the recent "Naturforscher Versammlung" in Hamburg a number of prominent German orthopedists decided to establish a German Orthopedic Association which is now in progress of organization.

General Hospital in Samara, Russia.—According to Dr. N. Senn, in the *Chicago Tribune* of September 1, as quoted in the *Journal of the American Medical Association* of September 7, the General Hospital at Samara is located in a handsome park near the western limits of the city, and consists of a number of wooden buildings, in barracks style. Each building does service for seventeen years, when it is removed and replaced by a new one. At present the hospital contains 400 patients. These patients are admitted from all parts of the Samara province and pay 20 kopeks a day. If the applicant is destitute, as is often the case, the district from which he comes pays this small charge for him. We spent half a day in the surgical section, in charge of Dr. Johannes Dsirne, a surgeon of more than a local reputation. We had the pleasure of witnessing two operations for stone in the bladder. Stone in the bladder is quite common in this section of the country, as this surgeon performs annually on an average 100 operations. Although the operating-room lacks many of the modern conveniences, the results obtained would compare well with those in our best equipped institutions, something we must attribute to the pedantic cleanliness of the operator and his assistants. The anesthetic, chloroform, was administered by a female *feldscheer* or barber surgeon, and two other women of the same grade of medical education rendered assistance. The chief assistant was a recent graduate in medicine. These barber surgeons, male and female, are expected to assist licensed physicians, but are not permitted to operate or prescribe except in cases in which the services of a regular graduate in medicine can not be secured. These barber surgeons must study their profession for four years, and the women are required to take an additional course in gynecology and obstetrics. Both patients were puny boys from the steppes of western Russia. In one case the high operation was performed; in the other the stone was removed by median perineal section after crushing. It is a fact worthy of note that according to the experience of Dr. Dsirne the peasants are almost immune against shock, ho in his large experience having only observed one case. Dr. Dsirne invariably sutures the vesical wound in performing the high operation, using two rows of fine silk sutures, excluding carefully the mucous membrane. In most cases uncomplicated by cystitis he has seen the wound heal by primary intention. If cystitis is present he drains. Dr. Dsirne is a careful, conscientious, and dexterous operator. I am glad to know that he will visit the medical institutions of Chicago some time next summer.

Appointments in Heidelberg.—Dr. Ludwig Braun and Dr. Siegfried Bettmann, both Privatdozenten have been appointed Professors at the University at Heidelberg.

2.—Kirker suggests that an operating room be included in the internal arrangements of every modern battleship and cruiser. It should be fitted up to meet the requirements of aseptic surgery. It should be well protected and easily accessible. He says it is not practicable to remove the wounded during action. They must shift for themselves until the battle is over or a lull occurs in the fighting. The conditions which have brought about this revolution in the treatment of the wounded are connected with the construction of modern ships and the nature of modern fighting. The duration of a modern naval action is short. The wounds are rarely attended with dangerous bleeding, as in the days of solid projectiles. There are few suitable places on board a ship where the wounded would be safer than where the bulk of the men are fighting, and during an action, as the Japanese found, surgeons are not able to do work of any value. The author mentions an "ambulance-sleigh" which he has devised for transportation of the wounded. [F. T. S.]

3.—Clayton says dressing stations for giving first aid during action should be accessible, protected, and in a position not to interfere with the fighting qualities of the ship; and the operating room and sick quarters should be so situated as to command cleanliness, roominess, ventilation, light and water. The position of the dressing station is decided by the peculiarities of the ship in question. In the dressing stations should be placed only the instruments and dressings necessary for carrying out first aid or emergency operations, with mattresses upon which the wounded may lie. It is doubtful whether sufficient space could be spared for an ideal operating room. Before an action three or more alternative spaces may be chosen for an operating room, such as the captain's cabin, ward room, and sick bay. After the battle one of them would probably be available, and into this the previously prepared operative accoutrements could be moved ready for immediate use. To prevent sepsis caused by the entrance of clothing into shell wounds, the author suggests that the crew shift before action into sterilized, or at least clean, clothing. For transportation of wounded stretchers are of little value during action except in the largest battleships, on account of the many obstructions, as ammunition-hoists, etc., and also from the scarcity of bearers. It is suggested that every officer and man be carefully trained in the ambulance drill, especial attention being paid to first aid dressings. [F. T. S.]

4.—The retention of the sick and wounded on board a modern fighting ship in war time is undesirable, unsanitary and depressing. It has been suggested that each fleet or squadron should be accompanied by one or more floating hospitals. Ninnis believes that these ships should be used for the care of the sick and the wounded only; that their

arrangements should embody all the essentials of a perfectly equipped land hospital, suitable for both medical and surgical cases, with the exception of the infectious fevers; and that the propelling power should leave ample space for the wards. Such a ship should have its decks provided with ports that may be easily opened and closed. The ship should be built of metal eased on the outside with wood, thus combining the cleanliness of metal with the non-conductibility of wood, and there should be no possibility of communication between the bilge and the wards. The wards should be absolutely without communication with each other, and each should have direct and independent air communication with the upper deck. The portion of the decks appropriated to water closets should extend across the ship, so that a through current of air could be secured. The water closets, when in use, should be absolutely shut off from this space. Platforms of such size as to accommodate a stretcher or lounge should be fitted outside the main and middle decks and the parts leading onto them should be of such size as to give easy passage to a stretcher or carrying chair. These ships should be lighted by electricity. [J. M. S.]

5.—The statistics of the Royal Navy show that iron ships are more healthy than wooden ones. This is probably due to the fact that in the former there is more space between decks, that they are dryer and that they are better lighted and ventilated. Home gives the following points that are necessary for the health of a ship: (1) Have certainly not less than 120 cubic feet of space for each man, and more than this in the tropics. (2) Have uptake ventilators from every compartment, opening as near the top as possible. These should be so constructed as to be capable of being cleaned by a brush pulled through them. (3) Cows and air-shafts are needed to be supplemented in all favorable weather by a wind sail for each hatchway and wind scoops for each port or scuttle in the side. Artificial ventilation is required for every space in which men live. (4) The ship should be warmed and kept dry by steam radiators. (5) Whenever decks are washed, the last washing should be done with a 1 to 1000 solution of perchloride of mercury or other antiseptic. The mess tables and stools should be washed in like manner. This reduces the liability of casual wounds to inflame. If the beams overhead could be sprayed with formalin solution once a week the occurrence of sore throats and other septic diseases would be diminished. The best general antiseptic on board ship, however, is plenty of fresh dry air. (6) There should be a drying room for the wet clothes and bedding of the ship's company.

[J. M. S.]

6.—The wars which compare with that in South Africa in regard to length, number of wounded, and strain upon the medical department, are the Peninsular and Crimean wars, the American Rebellion and the Franco-German war. Chloroform was first tested on a large scale during the Crimean campaign. During the Franco-German war the mortality after operation was tremendous from the various forms of infection, and a large proportion of those who died on the battlefield perished from hemorrhage. The large bullets then used inflicted most extensive damage. In the war between Russia and Turkey the first attempt was made to treat gunshot wounds of the knee antiseptically with astonishing success. The Lee-Metford and Mauser bullet inflict a small circular external wound, which soon becomes sealed with a black scab of dry blood. The exit wound is quite similar and closes in the same way. The intervening parts are but little damaged, and recovery generally takes place rapidly and without complication. The bullet seems to be aseptic, clothing is very seldom carried in with it, the track behaves more like an incised wound than a contused one, and the rapid manner in which the small external wound heals transforms the injury into a subcutaneous one. The manner in which the bullet may traverse the abdomen, thorax, cranium, the great joints and the important viscera, with but little constitutional or other disturbance, must be witnessed to be realized. Fatal primary hemorrhage is rare and traumatic aneurysms frequent. Large vessels may be wounded with but a limited amount of hemorrhage. The treatment is usually expectant, especially of those wounds involving the abdominal cavity. Formerly a gunshot fracture of the femur was a serious menace to life. Almost half the fractures of the femur in the Civil War were treated by primary amputation, and the mortality following the injury

was 50%. In the Spanish-American War, of 82 cases of gunshot of the femur, 6 were amputated, while 72 were treated conservatively. In the Civil War 1 man was killed for every $1\frac{1}{2}$ wounded, while with the Mauser bullet the proportion is 1 to $7\frac{1}{2}$. Six to eight per cent of the wounded now die, while during the Civil War the percentage was $14\frac{1}{2}$, the difference being due not only to the altered character of the injury, but to the improvements in treatment. [F. T. S.]

7.—After a study of the outbreaks of typhoid fever at the military stations in India, South Africa and Egypt, Canney concludes: (1) That the evidence of airborne typhoid recorded in Indian military experience is not established. (2) That in South Africa and Egypt the evidence is opposed to this theory. (3) That in India, South Africa and Egypt the immense weight of evidence and probability is in favor of a waterborne origin and spread. (4) That the evidence from Egypt proves that if the avenues to man by means of water be protected, all other avenues are powerless to originate and spread typhoid in large bodies of men. There is strong evidence to suppose that the same methods would bring about the same results in India, South Africa and other countries. (5) That the origin and spread of typhoid fever by means of flies and dust being theory only, it can only be discussed as such in relation to certain laboratory experiments, and that in practice it is unjustifiable to hold this theory, if it should deter, delay or hinder the adoption in armies of the most vigorous and comprehensive measures against waterborne typhoid fever. [J. M. S.]

10.—Hall Edwards speaks of his experiences in South Africa with the Röntgen rays, and gives a list of cases radiographed. [F. T. S.]

11.—An undeformed small-bore bullet entering at right angles to the surface makes a round hole slightly smaller than the bullet itself. Around this is a narrow zone about $1/6$ of an inch in breadth, from which the cuticle has been removed. These soon become covered with a scab. When the axis of a flight of a bullet is inclined at less than a right angle the skin wound is oval, and when the angle is very oblique the bullet traverses a certain tract of skin. In a ricochet bullet wound the bullet is often distorted and the wound becomes irregular and jagged, and even if not distorted it may strike the body with its side. A bullet extracted shortly after the receipt of the wound is lodged in a blood-containing cavity; later a fibrous capsule forms, and still later the fibrous capsule contracts and closely surrounds the bullet. Explosive wounds are practically always met with in connection with fractures of bones. The bullets emerge at an acute angle, thus accounting for the character of these wounds. Another form of wound is that in which the skin is blown away to a great extent. This may occur if the bullet emerges from a subcutaneous bone like the tibia, causing a crater-like wound. Sometimes the muscles and tendons are torn and extruded through the skin wound. [F. T. S.]

1.—Crichton-Browne delivered an address on the treatment of tuberculosis in sanatoria before the State and

Municipal Section of the British Congress on Tuberculosis. This author states that we should use the term "cure" as meaning an arrest of the tuberculous process. Like other severe diseases, by which the human body is visited, it leaves some scars on the constitution. We are informed that the presence of a calcareous nodule or a fibrotic patch in a lung does not warrant us in assuming that virulent tubercle bacilli are lurking in such foci. A renewed outbreak of the disease may be due to a fresh infection. A fact to be remembered is, that tuberculosis frequently exists in the lungs without in the least impairing the health of the individual, who may succumb to some other malady. A large number of cases of consumption, particularly those in the more advanced stages, arrive at a stage when the condition may be correctly described as arrested. In some of these cases, the disease is not extinct, while in others a favorable termination of the disease is reached, the patient enjoying good health and attaining a ripe old age without the slightest return of the phthisical state. The author strongly emphasizes that there is pathological and clinical evidence of the curability of consumption, and that this disease at times undergoes spontaneous cure notwithstanding the varied kinds of treatment to which it has been subjected. The present system of treatment by sanatoria is founded on a scientific basis. The results which have been obtained justify its employment. The measures which may be included in this plan of treatment are, fresh air, feeding, rest, and medical regulation. These, when skillfully handled, are sufficient in a large proportion of cases to effect a cure. Sanatorial treatment has already extended the curability of consumption and, at the present time, the medical profession has accepted this method as the best within the reach of those who are suffering from consumption. The author groups consumptives into three classes. (1) The affluent, comprising those who are under the individual guidance of a skilled medical adviser, and who can provide for themselves. The sanatorial treatment is not the kind to be recommended always for the affluent. (2) The competent. The people belonging to this class of consumptives have sufficient means to care for themselves during a brief illness, but when suffering from a protracted disease, which makes great demands upon their resources, such as phthisis, they are unable to provide for themselves and must depend upon public charity. Sanatoria should be provided for this class. (3) The indigent. To this class of consumptives is included a great mass of cases occurring amongst workmen, laborers, sailors, domestic servants, and shop girls, who support themselves while in good health. When ill they become indigent in the sense that they are more or less in need of help. The author suggests that sanatoria for this class of consumptives should be directed, and governed by the county councils and they should be designated as "county sanatoria." Friendly societies and sick clubs should be also organized which should have for their object the right to demand admission of consumptives into these institutions. The author recommends certain plans for the maintenance of sanatoria. [F. J. K.]

2.—Delépine considers the question of how the tuberculin test may be utilized for the stamping out of bovine tuberculosis. This author discusses the value of this test and the experiments that have been made with it, giving an analysis exhibited by tables, of its sources of failure; the influence of age and disease on the results of this test; the data collected in relation to the examination of milk from single cows with diseased udders; and a table representing the losses caused by the slaughter of tuberculous cattle. He arrives at the following conclusions: (1) The tuberculin test is almost infallible for demonstrating the presence of tuberculosis in animals under seven years of age, provided the agent is used with sufficient care. Clinical methods are more reliable than the tuberculin test, as it is employed at the present day, to show the presence of tuberculosis in older animals. (2) It is possible to stamp out tuberculous animals from a herd by means of tuberculin and thorough disinfection in the course of a year. (3) Periodi-

cal use of tuberculin will detect the presence of accidental infection in a herd of cattle in which there has been a preliminary removal of tuberculous animals. (4) Tuberculous animals between the ages of two and three years can be disposed of without serious financial loss. (5) It is doubtful whether private efforts without State help are sufficient for the extermination of tuberculosis at the present time. (6) Immediate slaughter should be resorted to in animals in a state of advanced tuberculosis and all cows with tuberculous udders. (7) Milch cows not showing advanced tuberculosis should be isolated and they may be slaughtered, if previously they have been suitably prepared. Invariably, milk from tuberculous animals should be sterilized by boiling. (8) Valuable breeding animals not presenting an advanced state of tuberculosis or involvement of the genital organs should be isolated. For a time they may be used for breeding purposes. The calves should be isolated and be provided with sterilized milk. Satisfactory results can only be obtained by measures which provide for the removal from a district, of all tuberculous animals, for the disinfection of all cattle sheds, and for periodical tests of all animals with tuberculin.

[F. J. K.]

3.—Bruce and de Maine Alexander discuss the treatment of melancholia. These observers believe that melancholia is a disease of disordered metabolism and that the treatment should be directed so as to increase the elimination of waste products through the channels of the urinary and integumentary systems. They accomplish this end by the administration of an abundant fluid dietary. This treatment has a tendency to lower the arterial tension and assist in the elimination of waste products which are contained in the blood. The good results which these observers have had by this plan of treatment, seem to indicate that it is founded upon a sound therapeutic basis. They append a report of four cases. [F. J. K.]

4.—Cottle and Dickinson report three cases of pruritus associated with lymphodermia. (1) This case occurred in a woman 42 years of age. Her illness began in the autumn of 1899, when she noticed a swelling in the neck and complained of weakness. A year later, she took to bed. At the time when she came under the observation of the authors, she was weakened physically and depressed mentally. In the neck, axilla, and in the groin, there were enlarged glands. The physical signs also presented evidence of a glandular tumor in the mediastinum. At this time, she had irregular fever, accompanied by frequent sweating. Several blood examinations showed that there were about 3,000,000 red blood corpuscles per c. m. The number of white cells varied from 8,000 to 14,000. The lymphocytes formed about 18% of the entire number of leukocytes. The skin covering the neck, back, shoulders, and outer side of the limbs and at times the whole body, was the seat of intense irritation. Later an eruption of pemphigus appeared on the legs. The treatment consisted in the administration of Fowler's solution, and of cacodylate of soda. The patient steadily grew worse. (2) This case occurred in a female 30 years of age who had been ailing with enlarged glands and anemia, since June 1896. The enlargement first appeared at the root of the neck. During the course of her illness, she complained of intense itching of the skin, which was especially marked during the night. Pigmentation of the skin also developed, which was particularly marked on the abdomen, around the eyes, and on the flexure of the elbows. Her condition was diagnosed by Sir William Gower as subacute lymphadenitis with Addison's disease. The patient died on February 2, 1897. (3) The patient, a male, 34 years of age, in December, 1896, suffered from septic rheumatism in a very severe form. This infection involved almost every joint of the limbs, also those of the neck and jaw. In 1897, enlarged glands were found in the groins, the axillae, and the neck. An abscess developed in the left thigh and failed to heal in spite of the frequent incisions. The adenitis continued to spread. In May, 1900, the general condition was one of profound lymphadenoma. The blood examination showed

nothing beyond leukocytosis which was attributed to the suppurating wound in the thigh. Pruritus of the entire skin was present throughout the illness. The condition of the patient steadily grew worse;—fever developed, dropsy made its appearance, and the patient sank from exhaustion and inanition on June 1, 1901. The author remarks that the arsenic which was administered during the illness was not responsible for the pruritus. [F. J. K.]

5.—Parker discusses **congenital hepatic cirrhosis with obliteration of the bile-ducts**. The following cases are reported: (1) A male infant had been under the care of the author for six months when death occurred. At birth, the infant appeared strong and well. In the third week the infant developed violent vomiting, and in consequence of this he was weaned. Jaundice soon developed; the stools becoming white. Later the abdomen became distended, the jaundice increased, and the liver and the spleen were moderately enlarged. The patient on one occasion passed a little blood per rectum. The condition of the child grew worse and death occurred. A post-mortem examination was made 50 hours after death. The tissues of the body were bile stained, fat was scanty, and the heart and lungs appeared normal. The liver was heavy, weighing 11 ozs., it was deeply bile stained. The organ was smooth and while not very pliable, it was not especially hard. Connective tissue existed about the bile-ducts; biliary calculi were not found. A portion of the common bile-duct was greatly distended and contained a clear fluid. Several enlarged firm glands were found in the portal fissure, in the mesentery, and behind the peritoneum. The cavity of the gall bladder was obliterated and there was also a complete absence of a part of the common duct. The spleen was firm and enlarged. A microscopical examination of the liver showed a large amount of fibrous connective tissue surrounding the lobules and crossing them in many places. An increase in the number of small bile-ducts was also noted. There were no degenerated liver cells. Second case. At birth this infant was deeply jaundiced. The mother had previously lost six children in early infancy, all of which were deeply jaundiced at birth. The infant lived seven months, during which time he was suffering from constipation. The stools were scanty and always streaked with a yellowish brown coloring matter. At the post mortem examination enlarged liver was found, and the author states that it was reported that the bile-ducts were replaced by connective tissue. (3) This patient, a male child, first came under observation nine weeks after birth when he was deeply jaundiced. The child was suffering from drowsiness and restlessness. A syphilitic rash was found on the buttocks. The liver and spleen were both enlarged, and this jaundice had existed since birth. The stools were generally white and occasionally pale yellow. The urine contained bile. Death occurred five weeks later. At the post-mortem examination, it was ascertained that the common duct was absent. Multilobular and monolobular cirrhosis and numerous small bile-ducts were seen in the microscopical sections. The author concludes that in some of these cases there was found a complete hypertrophic biliary cirrhosis differing from that form seen in adults by the fact, that there was a secondary obliteration of the bile-ducts. [F. J. K.]

6.—Marshall compares the value of **inunction with intramuscular injection in the treatment of syphilis**. This author has tabulated a number of cases which were treated by injection and inunction, respectively. In this analysis, he designates the time the patients were under observation, the amount and the preparation used, and whether relapses occurred. He concludes that the inunction method is more reliable and best suited when rapid mercurialization is desired. The only objections to this form of treatment are dirtiness and irksomeness. The advantages claimed for the injection method are the following:—It may be practiced by the surgeon himself; secrecy, cleanliness, and uniformity of dosage may be secured. Injection of perchloride of mercury always causes pain. [F. J. K.]

7.—Dalgliess gives a report of an epidemic of **catarrhal**

jaundice which was thought to have been caused by the enteric fever bacillus. This epidemic occurred in the summer and autumn of 1900 in Bloemfontein. The author directed over a hundred cases. At the time the epidemic prevailed there was also an epidemic of enteric fever, as well as prevalence of acute dysentery. The disease developed after the British occupation of Bloemfontein and therefore it seemed to have been spread by the troops. With the increase in the frequency of enteric fever and dysentery, so did jaundice increase. The indulgence in alcoholic beverages in no way seemed to play a part in the etiology, and the diet, whether it was composed of good food or improper food stuffs, did not seem to play a part in the causation. The same may be said in regard to the hygienic surroundings of the individuals. Digestive disorders did not seem to have an influence in the causation. The young and the old, the rich and the poor were affected alike. The author emphasizes that the epidemic of jaundice increased and fell with that of enteric fever and dysentery. It was common to find families, a part of the members suffering from jaundice, and others from enteric fever and dysentery. The author suggests that the enteric fever bacillus may have been the cause of the outbreak of jaundice. [F. J. K.]

8.—Ross writes on **meat albumin in the treatment of tuberculosis**. He contends that the meat albumin can be employed in a cooked or coagulated state with just as much benefit as in a raw state. We should never lose sight of the fact that it is possible for raw meat to be contaminated with pathogenic bacteria;—tubercle bacilli or spores of anthrax bacilli. [F. J. K.]

9.—Markie gives the results of the **blood examinations in 25 cases of scarlet fever** and summarizes his observations. He found a moderate anemia constantly. The hemoglobin percentage and corpuscular percentage were in direct ratio, hence the normal individual corpuscular hemoglobin richness was not altered. A leukocytosis was found in all the cases. This increase in the number of white corpuscles, with its important bearing in regard to diagnosis and prognosis, may be compared with the leukocytosis found in other diseases, notably croupous pneumonia. [F. J. K.]

MEDICAL RECORD.

September 7, 1901.

1. The Work of the Sanitary Department of Havana; with Special References to the Repression of Yellow Fever. W. C. GORGAS.
2. A Personal Experience in Radiography. ALEXANDER B. JOHNSON.
3. Can Nasal Catarrh and Catarrhal Deafness be Cured? CAROLUS M. COBB.
4. The Need for Better Provision for the Proper Care of Cases of Delirium Tremens and Cases of Doubtful Mental Diseases. HENRY C. BALDWIN.
5. A New Continued Fever. EDGAR J. SPRATLING.

1.—W. C. Gorgas presents the general methods of work of the sanitary department of Havana, with special references to the suppression of fever. The methods of quarantine are described and a number of tables are presented, showing the satisfactory decrease in the number of cases of yellow fever. Notwithstanding the fact that conditions are favorable to the development of the disease, there being a very large non-immune population in the city, and yellow fever having been introduced into Havana on a dozen different occasions, the authorities have, so far, managed to keep it out later than they have ever done before, April 1st being the date on which it usually makes its appearance. The war against mosquitoes has been persistently carried out, and Gorgas believes that this is the proper method of fighting the disease. [T. L. C.]

2.—A. B. Johnson, of New York, gives his personal experience in radiography, in which he discusses somewhat at length the use of the fluoroscope in surgery, the technique of radiography, the development of X-rays plates, and stereoscopic radiography. This latter method depends for its value upon the well-known principle of the stereoscope, that in order to see any near object, as a solid body showing relief, and to appreciate the special relations of differ-

ent parts of the body to one or another, it is necessary to view it with both eyes. The effects produced by the stereoscope depend upon the production of two pictures, taken from two different points of view, and the separations of the points one from the other is made equal to about the distance between the visual axes of the two eyes. [T. L. C.]

3.—C. M. Cobb discusses the curability of nasal catarrh and catarrhal deafness. 9 cases are detailed in his paper, representing the various varieties clinically found. Concluding from the history of the cases given, he remarks that each case must be carefully studied and it may be a question of weeks or even months before we can ascertain the cause of the discharge; but if we bear in mind that a chronic discharge into the throat is caused in the same way as a chronic discharge in other parts of the body, and study the case in this light, we shall be in a position to treat it intelligently. He believes the so-called catarrhal disease of the upper respiratory tract, with all its attendant complications, is curable and that, while many of the cases will require much time and observation, the results obtained will amply repay for this effort. [T. L. C.]

4.—Henry C. Baldwin, of Boston, presents a paper on the need of better provision for the proper care of cases of delirium tremens and cases of doubtful mental disease. He believes the first movement tending to proper care of these unfortunate people should be made by medical men. In order to learn what custom is followed at present he sent a number of questions to various authorities in 28 cities. He states that in Massachusetts the present method of caring for these cases is unsatisfactory. Aside from the humane standpoint, the establishment of separate hospitals or of special wards in connection with general hospitals for observation cases, would cost less than the present system, and many persons who are allowed at large, would come under early observation, and their condition would be determined in time to prevent crime. According to the Attorney-General, the cost of one murder trial in Massachusetts may reach \$15,000. [T. L. C.]

5.—Edgar J. Spratling describes a new continued fever, occurring in Forsyth, Georgia. The trouble begins with malaise for three or four days. The general symptoms resembled dengue, and in a few cases may be confounded with grip. The cases were of varying severity and the temperature reached 106.5°, in many not 100°. In dengue the surroundings have but little influence; in this they were nearly all-powerful. In dengue whole families are usually affected; in this rarely more than one member. He also found that the temperature was susceptible to the action of antipyretics. The symptoms lasted from 2 to 5 days, then gave way rapidly, all discomfort disappearing; the appetite returned, the pulse fell to from 85 to 100, the respiration to 30 or 40, and the patients expressed themselves as feeling well, but weak. But the erratic fever and the scanty urine persisted for from three to ten days longer and there were frequently profuse sweats. He believes that this is a close congener of, if not actually, Malta fever. [T. L. C.]

3. Generalized Vaccinia. JOHN H. HUDDLESTON.

4. A Massage Roller for the Application of Heat or Cold, Combined with Electricity.

ROBERT COLEMAN KEMP.

5. A Consideration of Hemorrhoids. JOHN TURNER.

6. Autotoxemia. WILLIAM W. PENNELL.

1.—W. P. Spratling, in his Study of Temperature Laws in Epilepsy, based on one thousand observations, gives the following: (1) In his conclusions Bourneville says, "Isolated attacks of epilepsy augment the central temperature." The only logical inference the author can draw from this statement is that Bourneville found the temperature increased after every isolated epileptic seizure, and nothing exists in Bourneville's work on the subject to change this opinion; (2) The results of the author's observations agree in part only with those of Bourneville, the latter's work having, in his opinion, lost much of its value through failure to properly classify the types of

seizures studied and to make due allowance for certain physiological differences in temperature; (3) After making due allowance for diurnal variation the author finds that 40 per cent. would be the lowest of such cases showing increased temperature after seizures, and 70 per cent. the highest, making the general grand average of cases of all types showing increased temperature after seizures 55 per cent., the difference in the results obtained by Bourneville and by the author being 45 per cent. The views of such eminent physiologists as Dalton, Kirk, Landols and Sterling, relative to the part played by muscular activity in creating heat, must in view of the activity of the muscular system in certain cases of major epilepsy have great weight in determining the cause of heat production in these cases, wholly irrespective of any influence that might be exerted by the heat centers in the brain; (4) By the results of the author's observations he is led to believe that in many petit mal and psychic attacks in which muscular activity plays so small a part, and in which the temperature is often increased after seizures, such increase is due to a disturbance either of the heat center that is thought to exist in the cortex of the brain, or of the center or centers that observers believe have been located in the corpus striatum and optic thalamus; (5) We find that subnormal temperatures follow epileptic seizures in greater proportion after grand mal than after petit mal or psychic seizures, the proportion being 15 per cent. of the former to 10 per cent. of the latter types; and that, while the author agrees in the main with Lemolne as to the cause of such low temperatures when he says: "Certain cases are naturally anomalous in the matter of temperature, having abnormally low temperatures in health," he does not believe that this explanation is altogether sufficient, but that there will usually be found to exist in these cases some chronic disease or general asthenic condition of long standing that lowers the stamina and vitality of the individual; (6) All that has been said by Bourneville, Lemolne and others, relative to the high temperature in status epilepticus, is confirmed by the tabulated results in the 17 cases referred to in this paper; (7) The temperature in serial attacks runs uniformly higher than in isolated attacks, but not so high as in status, serial attacks occupying midway ground as to frequency, severity, temperature elevations and mortality between isolated seizures and status epilepticus; (8) As a possible factor in establishing the presence of toxins or other agencies in the body prior to and possibly causing the convulsion, an effort was made to take the temperature in some cases when the aura was of sufficient length, before the attack; but it was done in one case only, and in this the heat, beginning two hours before the fit, ran steadily up to 102° F., when the patient passed into convulsion. [T. M. T.]

2.—D. J. Loring, in planning the proper surgical treatment, always has in view: (1) The limitation of the infected area to the fullest possible extent; (2) The provision of abundant drainage for ptomaines and leucomains and other tissue debris, the result of microscopic invasion; and (3) the introduction of some antiseptic, such as iodine in the form of iodoform, which will render the infected field sterile in the shortest possible time. [T. M. T.]

3.—Generalized vaccinia, of which J. H. Huddleston collected fifty cases, was found to be produced in the following manner. Of the 50 cases, 25 are males, 14 females, and 11 with sex not stated. The ages vary from three days to 62 years; 25 are under one year and there are six adults. 12 were vaccinated with bovine virus, either direct from the animal or preserved, 20 with humanized virus, one with cow-pox and one with horse-pox, the last two by accidental inoculation. The source of the virus in the other cases is not stated. In 20 per cent., 10 cases out of 50, the case was not vaccinated in the usual way; 8 of the 10 came in contact with the virus in a vaccine vesicle on another person and the 10th ate vaccine crusts given intentionally in food. This last case was reported in 1809, and the author has met no record of any repetition of the experience. Chauveau, however, induced a generalized eruption of vaccinia on horses by giving virus by the mouth, by inhalations, and by subcutaneous inoculations, so that the record of this case may not be scouted without further information. Six of the nine who contracted vaccinia came in contact with it in ordinary daily association or by sleeping with a vaccinated person; one bathed in the same water that had been used by a vaccinated person, and two sucked a vaccine pustule on the arm of another. Four of

the 50 were revaccinated and in them the primary vaccination had not caused an eruption; the other cases were all primaries. In four cases the eruption developed before the fifth day and in 28 cases from the fifth to the fifth day after vaccination. The rest appeared later. Rarely the eruption came out on one day, usually it appeared in successive groups for about a week. One well accredited case continued to develop the eruption until the 42d day. [T. M. T.]

4.—R. J. Kemp gives various uses of the **massage roller**: (1) Alternating heat and cold, combined with electricity, can be applied to the spine, as for neurasthenic conditions, etc. A similar application could be made to the abdomen for chronic constipation. Cold can be employed for headache, heat for sciatica, muscular rheumatism, lumbago, neuritis, intercostal neuralgia, rheumatic joints, etc. Hot massage for counterirritation may be applied over the kidneys and for acute congestion and for oliguria. Electricity combined with heat has proven of even more value in these conditions, the roller being applied over the lumbar region of the cord, as well as over the kidneys. The faradic battery is connected with the instrument. This may seem a novel procedure, but clinically this method has been found to be a valuable adjunct in promoting diuresis. The addition of electricity seems to increase markedly the counterirritation and reflex stimulation, produced by the heat. The hot roller can also be employed over the thorax in acute bronchitis, etc., as a counterirritant. If it is desired to use moist heat, the part can be covered with thin flannel wrung out in boiling water and the roller then applied over this. To employ dry heat the best effects are produced by lightly skimming the surface with the instrument. It may be passed over a thin linen handkerchief, if the patient be especially sensitive. The roller filled with boiling water is of considerable value for the purpose of innunction. Ointments made of lanolin can thus readily be rubbed in, as mercurial ointment in syphilis, or ichthyol ointment in rheumatism. To avoid damage to the instrument it should be lubricated with olive oil which does not readily amalgamate with the ointment. It can be readily cleansed in boiling water. [T. M. T.]

6.—W. W. Pennell defines **autotoxemia** as a condition of the bodily health modified by the absorption of harmful substances from the intestinal or genito-urinary tracts into the blood; poisonous substances originating within the body as the result of either defective metabolism and elimination or fermentative and putrefactive processes, or both, and producing well-defined symptoms. [T. M. T.]

2. Imperative Conceptions. HUGH T. PATRICK.
3. A Study of the Temperature, Pulse, and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain. J. T. ESKRIDGE.
4. The Therapeutics of Whooping-Cough. THOMAS J. MAYS.
5. An Unusual Case of Gastric Ulcer. FRANK H. MURDOCH.

2.—H. T. Patrick gives the prognosis of **imperative conceptions** as follows: The prognosis is affected especially by three factors: (a) The character of the imperative conception; (b) the degree or intensity of the trouble, and (c) the nature or disposition of the patient. Confirmed subjects of the doubting and questioning or reasoning psychosis, the *Grübeltsucht* of the Germans, seldom recover, while the phobias may ordinarily be cured or greatly relieved. Bad cases of long standing, of any variety, are exceedingly difficult to handle and require all the niceties of neurological techniques. Like other bad habits and tics, the earlier imperative conceptions are properly treated, the better the outlook. Pronounced neurotic heredity and neuropathic disposition are most unfavorable conditions. Assuming that a certain degree of unstable equilibrium or nervous susceptibility is necessary for the development of the malady, it will at once be seen that danger of relapse is never very remote, often imminent. [T. M. T.]

4.—T. J. Mays states that **whooping-cough** is unquestionably a spasmodic affection of the pneumogastric nerves, due to the affinity of a special virus for the latter struc-

tures, and in this respect bears a certain analogy to asthma and to other spasmodic disorders of the respiratory organs. Of its contagious nature there can be no doubt. A knowledge of its pathology is, therefore, quite satisfactory, but, when we come to treat it, the practitioner must confess that there is no disease before which he stands so helpless as he does before this. At least, this has been the writer's experience, who has administered every known remedy, running through a list of such drugs as the bromides, camphor, chloral, chloroform, bromoform, quinine, antipyrine, phenacetine, carbolic acid, etc., without the slightest permanent relief. In more recent years, however, and in conformity with his belief that disorders of the pneumogastric nerves are not only responsible for all the various forms of spasmodic cough, but also play an important part in the evolution of many diseases of the lungs, the author applied counterirritants over these nerves in the region of the neck with the most signal benefit in this disease. In fact, this method is the only one that has ever given the least promise of amelioration. The practical way of applying it is as follows: Trace the pulsating carotid artery from behind the angle of the lower jaw to the clavicle on both sides of the neck, two or three times a day, until the full effects of the mustard are evident. This is almost sure to cause amelioration of the spasmodic cough. Equal parts of gum camphor, chloral hydrate, and menthol applied over this region, are also very useful. Painting the same area with tincture of iodine, twice a day, until irritation of the skin is produced, is a beneficial procedure. Finally, in very stubborn cases the hypodermic injection of silver nitrate over the vagi must be resorted to in accordance with the following plan: Lift the skin over the vagus between the thumb and forefinger of the left hand, introduce the hypodermic needle just under the elevated skin, and inject five minims of a two-and-a-half-per-cent. solution of cocaine hydrochloride. Detach the syringe from the needle and allow the latter to remain in the puncture. Wash out the syringe with water, draw a two-and-a-half per cent. solution of silver nitrate into the syringe, attach the latter to the needle, and throw in from three to six minims of the silver solution. Under the influence of this line of medication the child becomes more comfortable, the paroxysms become less frequent, the severity of the cough diminishes, and altogether the affection assumes a different character, often in the space of a day or two. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

September 5, 1901.

1. Under What Circumstances (excepting emergencies) is it Desirable to Operate upon Gall-Stones for Radical Cure or for Relief. MAURICE H. RICHARDSON.
2. Obstructive Disease of the Lower Bowel. HENRY O. MARCY.
3. The Indications for Operation in Malignant Neoplasms of the Stomach. CHARLES GREENE CUMSTON.
4. Remarks on Tuberculosis and its Treatment. DR. BARADAT.
5. The Chemical Properties of Leukocytes. EDWARD T. WILLIAMS.

1.—The arguments in favor of **removing gallstones** at the earliest favorable moment after the diagnosis has been made may be summed up as follows: (1) The operation is, as a rule, easy and safe and all stones are quickly removed. (2) The remote dangers of gallstones are either avoided or lessened. These are: serious disabilities, grave emergencies and malignant disease. (3) If the diagnosis of gallstones proves to be wrong, other lesions may be discovered and remedied, lesions perhaps more serious than those of gallstones. (4) Late operations upon gallstones are, as a rule, difficult and dangerous. Operations made imperative by progressive and lethal symptoms must be performed under great disadvantages and dangers; the gallstones are generally more inaccessible, the dissections deeper and the patient's power of resistance lessened. The arguments against early operation are: (1) There is some danger in the operation, though it is but slight. (2) The diagnosis may be wrong and the exploration unnecessary. (3) There is the possibility of hernia in the scar. (4) There is the possibility that the gallstones may recur. (5) There is the possibility of spontaneous cure. (6) There is also the possibility that, after offending enough to prove the diagnosis, the gallstones may give no further trouble. (7) The last and decisive attacks of biliary colic

may have been caused by the last remaining gallstone, exploration showing that none of them remain. Richardson believes that the arguments in favor of early operation outweigh those against such operation and he believes that as soon as the diagnosis can be made the operation should be done. [J. M. S.]

2.—Obstruction of the lower bowel may be due (1) to the changes incident to injuries of the pelvis. Such changes are usually of an acute character; although, as a result of such injuries as fracture of the coccyx, changes may take place which while they do not produce positive obstruction, still impair the function of the lower intestine. (2) In the male, to diseases of the seminal vesicles and prostate and in some of old stone in the bladder. The same may be said of chronic distension of the bladder, though in the latter class of cases such a manifestation is rare. (3) In the female, to the infectious diseases of the Fallopian tubes with the secondary conditions dependent thereon, to small cystic tumors of the ovary or broad ligament, to retroversion of the gravid uterus and uterine tumors. (4) To the accumulation of foreign matter, particularly feces. (5) To structural changes in the wall of the intestine due to malignant growth. [J. M. S.]

3.—Surgical treatment of carcinoma of the stomach is indicated not only when stenosis is present, but also as a radical cure for carcinoma itself. Cumston believes that in every case in which carcinoma of the stomach is suspected an immediate exploratory celiotomy should be advised and every neoplasm that can be removed should be excised. In order to successfully perform resection of the stomach, and in order that its results shall attain the maximum of effectiveness, the surgeon should not wait for a clinically confirmed diagnosis of carcinoma of the stomach, because an exploratory celiotomy is justified in every case in which the patient is afflicted with gastric troubles, when analysis of the gastric juice shows an absence of pepsin and the presence of lactic acid, and when medical treatment carefully conducted is incapable of increasing the body weight and retaining it at the higher figure. The contraindications for resection of the growth are the general lowered condition of the patient, visceral metastases, immobility and adhesions of the tumor and the propagation of the growth beyond the movable portions of the esophagus and duodenum. The age of the patient, the presence of some enlarged glands, the size, the anatomical position and the extent of the growth in the walls of the stomach in no way contraindicate resection. [J. M. S.]

4.—See Philadelphia Medical Journal, Vol. VIII, No. 11, Proceedings of Congress on Tuberculosis.

5.—Williams believes that instead of classifying leukocytes as basophilic, neutrophilic and oxyphilic, we should classify them as acid, when they stain with alkaline dyes, neutral when they stain with neutral dyes; and alkaline, when they stain with acid dyes. The nuclei of all 3 varieties of leukocytes stain best with alkaline dyes and are, therefore, acid. They owe this staining property to the nuclei they contain. The bodies of the normal mononuclear leukocytes are acid; the bodies of the polymorphonuclear leukocytes are neutral; and the bodies of the so-called eosinophilic leukocytes are alkaline. These reactions Williams believes are due to the presence or absence of nuclei from the cell-body of the leukocyte. He also believes that the alkaline leukocytes are dying forms. They are almost invariably the products of disease. The eosinophiles are often associated with spermine and xanthin crystals, which, as is well known, are the products of the decomposition of nuclei and it would seem rational to suppose that the eosinophiles were undergoing decomposition. The author is inclined to place all alkaline leukocytes (oxyphiles) under the designation of necrotic cells. [J. M. S.]

11. Traumatic Affections of the Uvula.
SEYMOUR OPPENHEIMER.

1.—Zinke states that from his own personal experience, as well as from the statements of other authorities, that the present practice of obstetrics is not as satisfactory as it might be to any one class of practitioners of medicine and surgery generally, and the accoucheur especially. Antisepsis and asepsis in the management of labor are of inestimable value, but very often they cannot be properly carried out, successfully executed, or effectually met because of the patient's surroundings. Zinke prefers attending patients in labor in maternity hospitals where he can have the process carried through aseptically. [W. A. N. D.]

2.—Porter for years has been in the habit of delivering parturient women in the following position: The woman lies on her back across the bed, her hips well to the edge and on a Kelly pad so arranged as to carry the fluid into a vessel on the floor. For this purpose the small square pad is most suitable. The patient's limbs are separated and extended, and are supported by assistants, by a couple of suitably placed chairs, or over the knees of the obstetrician. This position is maintained from the end of the first stage until the termination of labor, unless the second stage be tedious. In that event the patient can resume her ordinary position in bed to be again brought into the position described before the end of the second stage. The position is not tiresome to the patient or to the physician, and can be maintained for hours without discomfort to either. He claims for this position that there is less liability of infection with the fecal bacteria, fewer examinations are necessary, there is better control of the head at the time of delivery, and consequently less danger to the perineum, the woman can be more thoroughly cleansed, the clothing and bedding are not soiled, and there is less danger of infecting the eyes or cord of the child and less risk of its aspirating fluids into the air-passages. [W. A. N. D.]

3.—Moran, in speaking of the prophylaxis and treatment of puerperal sepsis, remarks that the treatment of sepsis will depend upon the skill and judgment of the physician and the condition of the patient. It would not be justifiable to open the abdomen without some physical reason. The different forms of sepsis should be thoroughly understood, for an operation would hardly be required except in pathogenic infection. When the operation is performed early, many organs will be needlessly sacrificed, and if performed late, the mortality will be increased. When there is continued fever with increasing physical signs, the operation is permissible; without the latter general symptoms would indicate systemic infection and surgical measures would only hasten the end. As to the value of the antistreptococcal serum the results have, on the whole, been disappointing. Statistics show the mortality to be about 35%. Many of the failures may have been due to the inferior quality of the serum. It is important to determine whether the case be one of simple or mixed infection. Curative effects are claimed for only a simple streptococcus infection. [W. A. N. D.]

4.—Fry claims that the curette is a valuable instrument in the hands of the obstetrician, as well as the gynecologist. In abortion, when the cervix cannot be dilated sufficiently to pass the finger, the curette must be used as a substitute; and again when the expulsion of the product of conception is in the later months, the finger is unable to reach the fundus uteri. The indications for its employment to remove the retained products of conception and blood-clots are clear. Decomposition of the retained tissue, accompanied with a foul odor of the discharge and febrile reaction indicates the use of the curette. In streptococcal infection the curette is contraindicated, and also in infection existing in some laceration of the vulva, vagina, or cervix without involvement of the cavity of the uterus. [W. A. N. D.]

5.—Humiston reports a case of *streptococcus* infection following labor in which a vaginal section was performed and Douglas's pouch cleansed with a hot salt solution and iodoform-gauze introduced. The patient made an uninterrupted recovery. [W. A. N. D.]

6.—McCosh concludes his article on *spinal surgery*. Operations for spinal lesions have been more satisfactory than those for cerebral lesions. The reasons for this are greater accuracy in the location of the lesion and the less permanent damage which is done to the cord prior to operation. The symptoms of spinal tumor are well marked and within certain limits can be accurately located. It is impossible to assign a certain lesion to any one segment of the cord, but it is usually possible to locate a lesion to an area embraced by three spinal segments. There is no spot on the surface of the body and practically no muscle which is innervated by one nerve root alone. Anastomosis between the spinal nerves is so perfect that the sensation of any one spot and the motive power of each muscle is derived from at least two segments of the cord. In addition the afferent and efferent tracts run up in the substance of the cord for some distance, perhaps two segments, before it reaches the real nerve center in the gray matter of the cord. Consequently it is easy to be mistaken and locate the lesion lower than it really is. Tubercular masses are among the most frequent causes of pressure on the cord. Of spinal tumors the most common are the sarcomata. If the operation be useless as far as removing the growth is concerned, the agonizing pains may be relieved by division of appropriate nerve roots. At least three roots should be divided because of the free anastomosis between the sensory nerve. No case has yet been reported of recovery following the removal of an intermedullary tumor, or of a tumor from the ventral side of the cord. The higher up in the cord the tumor is situated the worse is the prognosis. The operative mortality should not be more than 10%. Operations should be done at the earliest possible moment, and no time wasted giving anti-syphilitic treatment if there be no syphilitic history. Of 51 cases of operation for tumors collected by Lloyd, about 10% died and 31% recovered. A frequent difficulty in these operations is to determine the exact position of the different spinous processes. This is especially true in the cervical region. The incision should be made as high as possible in order to secure abundant nutrition in skin normally supplied by nerves, and because of the reason already mentioned that the tumor has usually been found above the point localized by the physician. Operation should be done rapidly and ample space provided for. Support of the spinal column after operation is unnecessary. Of the methods of exposing the spinal cord, McCosh employs a vertical incision with division and separation of the muscles attached to the posterior portion of the vertebral column. The lips of this wound are widely separated and the spine and laminae removed by bone forceps. McCosh has operated six times for spinal tumor, with no deaths from operation. One patient is well at the end of more than a year, and another at the end of two months. Two died from sarcoma of other organs and one died at the end of two months from sepsis, from bed sores and cystitis. Of these six cases four were sarcomatous, one a fibroma and one tubercular. [F. T. S.]

7.—Eve advocates operation for spinal bifida, and reports a case of a child aged three months with a rapidly developing tumor in which the pedicle was small and which was operated upon. The outlines of the proposed operation are as follows: After incising and dissecting back the skin the sac is tapped and incised so as to leave two flaps, one longer than the other, being careful to avoid any nerves which may be adherent to the sac. The flaps are closely sutured so that leakage will not occur and the operation completed by suturing the skin. [F. T. S.]

8.—Fairchild concludes his article on the immediate and remote effect of brain injury by saying that violence of no great intensity, when applied to a limited area of the skull, may cause a fracture with only a momentary displacement with a rupture of a meningeal artery, or a rupture of an artery without fracture. A localizing injury which may lead to a fracture without displacement and hemorrhage, does not, as a rule, cause a serious permanent brain lesion, if early and judicious surgical treatment is employed. A fracture may occur without apparent displacement, yet the pressure on the brain exists which may cause remote results. A blow may be received on the head which may

produce an extensive laceration of the scalp, which in itself is not serious, but the fall from a height from a rapidly moving train may produce extensive contusion or laceration of the brain. The same character of injury may without fracture cause a contusion or laceration of the brain tissue or so disturb the cerebral spinal fluid as to cause immediate or remote serious results. An injury may be of such a character as to produce a localized wound of the brain that may heal with production of scar tissue which may extend and undergo cystoid or other degeneration with serious remote effects. In the absence of localizing or other definite symptoms the character of the accident, the manner in which the force is applied is of great value in reaching a conclusion as to the probable nature of the brain injury. [F. T. S.]

9.—Cotton reports a case of *diabetes mellitus*, which occurred in a girl aged six years and three months. This case was presented at the author's clinic on February 1, 1901. The family history was unimportant, as there had never been a history of diabetes, gout, tuberculosis, and syphilis. The child had had the following illnesses: Summer complaint, whooping-cough, chicken-pox and measles. The present illness began in April, 1900, when the patient was nervous and irritable. The appetite was variable, and the child began to emaciate. Some months later, it was noticed that she drank large quantities of fluids and passed much urine. In September, she was compelled to discontinue school on account of nervousness and frequent micturition. On February 1, 1901, her weight was 32 pounds, she complained of weakness, the skin was dry and the teeth were carious; the tongue red and clean, and the bowels constipated. 84 ounces of urine were passed in 24 hours. The reaction of the urine was acid, its specific gravity 1028. Albumin was present, and there was a decided reaction for sugar. The patient was given an anti-diabetic diet and pancreatic extract, and the constipation corrected with sodium salts. Careful observations as to the amount of sugar and quantity of urine were made daily. The child developed diabetic coma and died on March 11, 1901. The author concludes the article with a brief outline of the etiology and treatment of diabetes mellitus in childhood. [F. J. K.]

10.—Rathmell discusses *albuminuria* in disease of the kidney in childhood and infancy. The author states that while the presence of albumin does not necessarily indicate a serious organic lesion of the kidney, its presence should, however, command watchfulness and care on the part of the physician at all times. Albuminuria does not necessarily render the prognosis unfavorable. He classifies the causes of acute and chronic nephritis as follows: 1. Renal congestion. 2. Definite lesions of the kidney. 3. Indefinite causes. 4. Accidental causes. 5. Febrile disturbances. 6. Indefinite lesions. A report of a case of parenchymatous nephritis is given which occurred in a boy 4 years of age. The urine contained a very large amount of albumin—about 2/3 of its bulk—its specific gravity was 1040, and the shade of its color dark. The amount was copious. Edema of a decided character, involved the face, the lower and the upper extremities. The abdominal cavity was ascitic. The diet consisted of sweet milk, as long as the patient could take it, and afterwards stale bread was added. The patient was also allowed oranges and lemonade. The following laxatives were administered: Epsom's salts and cream of tartar, a solution of citrate of magnesia. A solution of lactate of strontium and Bashan's mixture were also used. The child died from uremia and pulmonary edema in about ten days. Another case of nephritis is reported which occurred in a boy five years of age. Six months after the onset of the illness, he had completely recovered. [F. J. K.]

11.—Oppenheimer mentions the rarity of injury of the uvula. The structure and mobility of the uvula render it exempt from traumatism which may affect the adjoining tissues. The causes of trauma are foreign bodies, which crush the uvula against the pharyngeal wall, minute bodies, such as a bristle, which pierce the mucous membrane, caustic materials, operative procedures on the tonsils and neighboring structures, and indirect traumatic influence such as that which results from the excessive or ill-advised efforts at vocal exercise. Edema is not as a rule well marked, and septic infection rarely follows. The symptoms are pharyngeal discomfort, constant desire to swallow, painful

deglutition and changes in the voice. Dyspnea only occurs when the tissues are enormously swollen. Cough is not commonly present. [F. T. S.]

AMERICAN MEDICINE.

September 7, 1901.

1. Correction of Occipitoposterior Positions Through Seizure of the Anterior Ear by Two Fingers in the Vagina. ROBERT L. DICKINSON.
2. Diseases of Sin. (Concluded). GEORGE M. GOULD.
3. Resections and Exsections. FERNAND HENROTIN.
4. What is True Conservatism in the Treatment of Appendicitis? MILES F. PORTER.
5. The Manifestations of Rheumatism in Children. WILLIAM FITCH CHENEY.
6. The Unusual Type of Smallpox with Fatal Termination. LOUIS LEROY.

1.—According to Dickinson the methods in vogue for rotation of the occiput forward are: (1) knee-elbow posture before labor or before the head engages; (2) lateroprone posture on the side to which the occiput points; (3) flexion, which accompanies every method; (4) pressure with two fingers on the temple; (5) seizure of the head in the hollow of the hand introduced into the vagina; (6) forceps in the ordinary application; (7) forceps reversed; (8) high manual internal rotation. He now suggests a simple method which has often proved successful, namely: seizure of the ear, and the exertion of pressure or traction to turn the head. This method is available whenever the ear is within reach. Two fingers are introduced beneath the pubic arch and the ear is caught between their tips. The palm toward the pubes gives the longer reach, and the anterior ear offers a better purchase for rotation of the occiput forward than any other simple method. [W.A.N.D.]

3.—Henrotin presents some salient points concerning the questions involved in resection of the ovaries and tubes. Salpingotomy and tubal resection is a most desirable operation, and only the most formally expressed desire for offspring on the part of the patient after explanation of the uncertainty of results will warrant their performance. Pyosalpinx always demands excision, and any tube materially damaged by any disease should be removed in its entirety. All the diseases of the ovaries adjudged to be nonmalignant can be cured, and should be treated by resection of the diseased portions only. Recent ovarian abscess can be cured more quickly, more certainly and with less danger with vaginal incision when this is practical. When the abscess is of long standing the sac should be removed, but even then some healthy ovarian tissue can almost invariably be preserved. In most diseases of the composite nature in young women when the tubes and ovaries are materially and equally involved, salpingectomy with ovarian resection is the most satisfactory operation, the uterus being retained. [W. A. N. D.]

4.—Porter says of 100 cases of appendicitis treated medically, 20 will probably terminate fatally, whereas timely operation will save 98. All patients dying of appendicitis after operation receive the verdict of "death from appendicitis," while a large number that die without operation are reported as deaths from bowel obstruction, etc. Timely diagnosis and early operation is the truly conservative treatment of appendicitis. The immediate mortality is less than 2%. The dangers of hernia, bowel obstruction, recurrence and secondary abscess are very small. [F.T.S.]

6.—W. F. Cheney discusses the manifestations of rheumatism in children, with notes of a number of cases. As to the manifestation in the joints, they are described as less severe than those which occur in adults. The swelling is less, and the redness is often missing entirely. There is a stiffness in the joints and resistance to motion, pain when used and disinclination to exercise. The symptoms are more apt to be limited to one joint and the constitutional disturbances are very slight. Temperature rarely rises to 102°. The sweats so common in adults, are not seen in children. Care must be taken to distinguish the pains from the so-called "growing pains." It is especially to be noted in connection with rheumatism in children that the endocardium is so frequently affected. Much has been said of the relation between rheumatism and chorea. In 29 cases of the author's series, 27 showed no history of rheumatism. He believes that this may be assuming that some joint manifestations really occurred previous to the chorea, or that the chorea was the first

manifestation of a rheumatic series. He records two cases showing the relation between one form of purpura and rheumatic manifestations in the joints. He mentions the subcutaneous nodules at times found in the fibrous tissue, as an occasional manifestation of rheumatism in children, and speaks of the grave significance of this. He mentions the relation of tonsillitis and rheumatism as remote, and he does not believe that it should be spoken of as a rheumatic manifestation at all. [T. L. C.]

7.—Louis Leroy reports an unusual case of smallpox with fatal termination. The patient was a colored woman of 30 years. Upon the third day of illness, an eruption appeared, until at the seventh day it was fully pustular. The secondary fever was well marked and started to decline, when upon the eighth day, all the pus in the pustules became absorbed, leaving the skin somewhat loose where the pustules had been. In no sense did it give the appearance of a rapid desiccation nor were any of the pustules present as is the case when ordinary desiccation occurs rapidly. At necropsy the skin was found to be smooth and soft, and there was no pus in any of the pustules which were opened. The heart muscle was soft and flabby, and a small antemortem clot was found in the right ventricle. [T. L. C.]

15. Ventilation of Crowded Places. THOMAS GLOVER LYON.

2.—Nathan Raw discusses the question as to whether the State should undertake the prevention and treatment of consumption. It is admitted that the disease may be completely arrested in its early stages, and even when fairly extensive, great improvement will follow treatment. In fact, the patient is in many instances able to act again as bread-winner for some considerable time. From a national standpoint the greatest attention must be directed to means of prevention rather than cure. It is estimated that over a million persons die every year from this disease in Europe, and that of this number 60,000 persons die annually in Great Britain. This writer maintains that tuberculosis should be treated as a special disease, and not on the general lines applicable to other infectious diseases, which are totally different in origin and progress. For this reason he says, it should not be included in the list of compulsorily notifiable diseases, such as smallpox, scarlet fever, and diphtheria, which run a rapid course, are highly dangerous to the community, and have a short and rapid termination. He calls attention to the recent Act of the Province of Ontario Government on the prevention and treat-

ment of the disease. The main provisions of the act are to allow any municipality of the Province to establish sanatoria for the treatment of consumption, and to raise the necessary funds for the purpose. He argues that this is precisely the step which England should take. Another grave aspect of the question must be met in a very short time, and that is, what is to become of those who are engaged in offices, workshops, and factories who are suffering from tuberculosis in its early stage? He advises the erection of large numbers of sanatoria throughout the country, and the proper housing and betterment of the hygienic conditions of the poorer classes. He discusses the economic aspect of the question. He suggests that tuberculosis should be included among the list of infectious diseases, but only to the voluntarily notifiable, and that a special code of rules and regulations should be drawn up for the guidance of health authorities. By-laws should be drawn up and strictly enforced regarding spitting in public places, and leaflets should be distributed free of charge to the public, setting forth in plain language the dangers of the disease. [T. L. C.]

3.—Arthur Newsholme contributes an article on the notification of phthisis pulmonalis. The preventability, as well as the curability, of a large portion of cases of this disease, is universally admitted. We have to deal with a disease, which, in 1899, caused a death-rate of 1,336, and including other forms of tubercular diseases, of 1,911 per million of the population. During the same year the chief acute infectious diseases were responsible for a death-rate of 1,248 per million. The importance of phthisis is increased by the fact that a large number of the loss caused by it occurs during the most useful years of life, and that it is preceded by more protracted illness. Comparing the present figures with those of a generation ago, Newsholme states it as his opinion that the present figures are now probably being under-stated and that the former were over-stated. When due allowance is made for these facts, there has, nevertheless, been a great decline in the death rate since 1861 to 1865 when it was 2,527 per million. This shows a decrease of 50%. This decline has been made use of as one of the chief arguments against the notification of phthisis and the more direct measures of prevention which would be its result. Inasmuch as the mortality of phthisis has been shown as being declining and to be declining at an increasing ratio, what further measures are necessary to be enacted against the disease? He gives these in their order of importance. 1. Improved nutrition of the population, due to better, more varied, and more abundant food. The increased consumption of meat has, he thinks, erroneously been credited with having caused increased cancer mortality. In all probability this is not the fact, but it has decreased the death-rate of consumption. 2. The improved housing of the poor, which, however much open to criticism, is better done than a generation ago. 3. The drying of the soil. He holds that the present infection is the main cause of the spreading, and that this occurs chiefly where people are most closely agglomerated, and live an indoor life, and that deficient nutrition is an important cause of the disease, and the wetness of the soil operates in a minor degree by favoring catarrhal conditions. He gives the following scheme of preventive measures, which he believes to be thoroughly practicable. A. Means of ascertaining the existence of the disease, under which he places the bacteriological diagnosis and the notification of cases, voluntary or compulsory. B. Direct preventive measures, which include laws against expectoration in places of public resort. Disinfection and cleanliness. Isolation and general sanitary improvement. C. Education of the public and of patients as to the importance of the preceding measures. As to notification, the main reasons why this is desirable are, that it enables instruction to be given to the patient and relatives as to the exact precaution required, and facilitates the removal of the insanitary conditions of home and work which may have caused the case or favored its progress. The only valid reasons that can

be urged against such notification are that the first of the above measures can be followed out by the family practitioner, with the co-operation of the family of the patient, and that the third measure named above forms part of the routine of the sanitary authorities. Against this it may be said that the information derived from compulsory notification will be more complete than that derived from voluntary notification. It would not only direct attention to insanitary houses, but also to dangerous persons, and assist the authorities in detecting sources of infection. A modified compulsory notification rendering it obligatory on every person suffering from consumption to notify any change of address would be of great value. If notification was compulsory, it would remove the difficulty which some practitioners feel in notifying the illness of their patients to a medical officer of health, when such notification is not imposed upon them as a statutory duty.

[T. L. C.]

4.—R. Mander Smyth gives his personal experience with galloping consumption. He furnishes the details of his own case and experience and the method by which he recovered. The open air, rest and at home had been the familiar and inefficient methods at first employed. The food was inadequate and the rest was not absolute. He went to Nordrach where he remained a year and returned in excellent health. He states that isolation from sympathetic friends was absolute peace and soon produced an effect on the temperature as well as upon the pulmonary germ.

[F. L. C.]

5.—Hector Mackenzie presents a paper on open-air treatment in London. When a patient is confined to bed and is treated at home or in an institution in London, he urges that an attempt should be made to secure the freest possible supply of air, that the patient should be outside the house, sheltered from the wind and receiving the maximum of sunlight. While indoors the airiest and sunniest room should be given up for his use. The room should be a very scantily furnished one, and a fire is not necessary or even desirable while the patient is confined to bed. When unable to take exercise, the recumbent position must be insisted upon, as the warmth of the body is much better maintained in this position than in any other, and a greater decrease of temperature can be endured. The patient will be perfectly warm, although in some cases hot-water bottles are useful. There is no danger in breathing cold air, providing the body itself is kept warm. The patients are, as far as possible, protected from the wet and wind by mackintoshes and tarpaulin screens. Warmth is maintained by a liberal supply of blankets, while woolen gloves and a woolen cap are worn on cold days. The return of appetite was very noticeable as well as the strength of the patients. The food supply was liberal and there was no need to urge patients to take food. Notes of three cases are given showing the excellent results of this treatment. [T. L. C.]

6.—E. Clifford Beale and Hugh Walsham treat of the diagnosis of tubercular disease of the lungs by means of the Roentgen rays. Nine excellent illustrations and points of difficulty in the interpretation of X-rays photographs are given, and the description of the various shadows which may be mistaken for tubercular deposits. They state that it is essentially in the early and doubtful cases that the assistance of Roentgen rays is most needed. They believe that the routine X-ray examination should be made in every case, as is done in their wards at Victoria Park. [T. L. C.]

7.—J. J. Perkins discusses the early diagnosis of pulmonary tuberculosis. The early diagnosis of phthisis is most necessary to the attainment of good results and must not be excluded by the problem of treatment. The acute or apparently acute onset, is far from uncommon and such cases are very apt to be wrongly diagnosed. The earlier signs of the disease must be carefully studied. The condition of the lung at the time of the tubercular invasion must be recognized. The process seems to start in the wall of the bronchus, from which have resulted small areas of lobular consolidation and tubercular nodules. No

extensive consolidation or softening of the affected lung has yet occurred, and consequently marked dullness, bronchial breathing of any extent, and rales in any abundance, the result of softening, are not to be looked for. Some diminution of resonance, however, can usually be recognized, best by tapping the clavicle lightly with the forefinger and comparing one apex with the other. The early foci of tubercle usually lie rather posterior than anterior in the apex and the supra-scapular fossae often yield more information than the front of the chest, both to percussion and other methods of examination. More aid can usually be gained from auscultation than from percussion. The expiration is prolonged, bronchial or broncho-vesicular. Either inspiration or expiration is often of the cog-wheel character. This sign, though meaning nothing, when heard widely, is of value when confined to one apex. Tactile fremitus may be increased at this stage, but auscultation of the voice is the more delicate test of the increased conduction in early consolidation. There is marked increase—best observed when the patient whispers. Conduction of the cardiac sounds, so that they are well heard at one apex, is another common and important sign of consolidation in these early stages. The presence of *tachycardia* and *hyperesthesia* should always awaken suspicion. Night sweating, even if only occasional, is a very suggestive and dangerous symptom. As a general rule *pyrexia* may be expected, though afebrile cases occur. No great rise of temperature need be looked for, a persistent evening rise to 99.5°—100.5° being quite sufficient to indicate the disease. The temperature should be taken at 4 P. M. to 6 P. M., and in cases of doubt every four hours, that no rise may elude observation. The disease may advance without expectoration being present. The use of the tuberculin and the method of its employment is discussed as a means of diagnosis. The recognition of initial *hemoptysis* on which *phthisis* so often follows, occurring in people apparently in perfect health, should awaken suspicion. *Pleurisy* is becoming to be regarded of tubercular nature, and it is often stated that only 2% of cases of *pleurisy* fail to develop pulmonary tuberculosis. [T. L. C.]

8.—St. Clair Thompson presents a paper on *tubercular infection through the air-passages*. The study of 100 autopsies naturally forms the inquiries: Why is the nose so seldom attacked by tuberculosis? How does infection reach the lungs? Why does the larynx stand midway between the two in its susceptibility? As to the first question, the microbes in their passage through the nasal chambers are entrapped in the vibrissae lining the nostrils. Others which penetrate any distance are enveloped in the sticky mucus; while the action of the ciliated epithelium promptly secures their expulsion. Phagocyte action also comes into play, and by the time the air current reaches the pharynx it is practically germ free. With these arrangements, with the trickling of tears, and the tendency of the Schneiderian membrane to resent foreign intrusion by increased *lacrymation* and sneezing, it is little wonder that tuberculous infection rarely reaches it from the atmosphere. There is no part of the whole respiratory tract which is so seldom attacked by tuberculosis as the Schneiderian membrane. The author believes that it is in the neighborhood of the *naso-pharynx*, and in the pathological conditions commonly affecting it, that we should look for the direct channels of infection of the bacillus tuberculosis. As to the character of adenoid growths, 5 to 6% show tuberculous character. Numerous observers have failed to find latent tuberculosis of the adenoids or tonsils. Discussing the possibility of absorption through the tonsils, the supposition appears possible that bacteria may continually be making their way into the tonsillar tissues, but at the moment of entering encounter conditions which terminate their existence. Primary tuberculosis of the larynx is not unknown, but is most uncommon. From his observations he draws the conclusion that we are compelled to view with a strong suspicion as a probable frequent focus of tubercular infection that ring of lymphoid tissue which surrounds the naso-

pharynx, the cross-roads where the food and air ways pass each other. There appears to be no justification for the generally accepted idea that the bacillus is inhaled directly into the pulmonary alveoli. [T. L. C.]

9.—George F. Still treats of *tuberculosis in childhood*. Among 769 autopsies on children under twelve years of age, he found tuberculous lesions in 269 cases, and in 223 of these, that is, in 23.9 per cent., the fatal result was due directly to tuberculosis. Figures indicate that nearly one-third of the child-mortality is due to tuberculosis. Statistics show that liability to tuberculosis is much more marked during the first five years of life than during the later years, and the significance of this very marked age-incidence is a matter of considerable practical importance. He discusses the question of milk infection, but states that the facts of the post-mortem room are overwhelmingly against this theory. The facts of the post-mortem room would tend that the disease in children is a lung infection and not an intestinal infection. Therefore inhalation infection must be carefully studied. He discusses the fact of measles and whooping cough with their subsequent liability to tuberculosis as two of the factors which help increase the special age incidence of tuberculosis during the first years of life. The lung affection in childhood tends to be not only a more acute process, but also more diffuse than in the adult. As to treatment first and foremost in the prevention is fresh air, through ventilation, and the spending of several hours daily in the open air. Overcrowding must be scrupulously avoided. [T. L. C.]

11.—Albert Catless contributes an article on the *surgical treatment of tubercular disease*. Tubercle is not like cancer or other malignant diseases. It is spontaneously curable and this fact must be remembered. It must be admitted, however, that such cures are usually very slow, often taking months or years, and the cure is not always permanent, nor is the patient exempt from risk during the time the cure is being accomplished. On this account the disease may become disseminated from its original locality to other parts of the body. Conservative treatment does not always lead to satisfactory results locally, deformity and functional disability to a greater or less extent being frequently present. Total extirpation of the tubercular focus is the ideal treatment, and for some lesions no other procedure need be considered, for instance in dealing with external lymphatic glands, as in the neck, should there be any hesitancy in the process of cure by general means. Ordinary operative risks such as arise from the danger of hemorrhage or sepsis, may be practically omitted, as they are extremely small. Care must be taken that the tubercular material is not set free by the manipulations during the operation. Finally, we must remember that post-operative disabilities are to be considered. As to conservative treatment, the absorption or encapsulation of tubercular foci can be effected by bringing antiseptics into such relation with the diseased material as shall hinder its progress and growth, and development of firm fibro-cicatricial tissue about it, and by modifying the fluids which soak the tissues affected, so that the bacilli do not find suitable pabulum in it, or even find therein substances inimical to their development. The author mentions the various methods employed with these ends in view. They include the injection of antiseptics, generally iodoform and the sclerogenic treatment, i. e., the injection into, and around the tissues, of 10% solution of chloride of zinc. The method of treatment by producing passive congestion is based on the fact that the bacillus tuberculosis does not thrive in parts that are soaked with the blood serum, exuded from the vessels. The plan of inducing congestion by means of an Es-march's bandage is chiefly applicable to bone and joint trouble. The intravenous injection of cinnamic acid and its salts, as well as the employment of tuberculin is mentioned. In the course of the article the treatment of chronic abscess, tubercular disease of bone, tuberculosis of the testis, the kidney, and the bladder, are discussed. [T. L. C.]

12.—Fredrick E. Batten discusses some tuberculous affections of the nervous system. He states that it is a well recognized fact that phthisis is not uncommonly the cause of death in cases of peripheral neuritis, but it is by no means so generally recognized that peripheral neuritis may occur in cases of advanced tuberculous disease of the lungs, the symptoms due to the changes in the peripheral nerves being probably overlooked or regarded as part of a general wasting disease. The question at once arises whether this is due to some toxin form or due to some concomitant condition. The discussion of this question by no means proves that the neuritis which occurs in tuberculous disease is due either to the toxin of tubercle, or that it is due to some other form of infection or to alcohol. The author states, however, that it is probably the result due to a concomitant action of some two of the poisons, considering the frequency with which alcohol is given in case of advanced phthisis. It is reasonable to suppose that this may be one of the most common causes of the condition.

[T. L. C.]

13.—Leonard Robinson presents an article on **zomotherapy** in phthisis based largely on the researches of Richet and Hélicourt. Raw meat in dogs, and probably also in man, increases the strength and excites the appetite in a very marked manner. It is a stimulant and a tonic to the nervous system. The action is to be explained by the impregnation of the nerve cells which have absorbed certain elements of the plasma. The solution of the problem is not of immediate interest to the physician, but the fact that zomotherapy is not a method of hyper-alimentation is of interest. In the muscle juice extracted from 500 grammes of meat the quantity of albuminoids, 18 grammes, is almost negligible, and cooked meat, given in large doses at which raw meat is curative seems to act as a toxic substance and rather to favor the evolution of the tubercular process. Another point of interest is the fact that the success of zomotherapy is a question of dose; success depends on a minimum ratio between the weight of the patient and the quantity of muscle juice or raw meat taken by the patient. Below this minimum limit amelioration is possible, but a cure must not be expected. A satisfactory formula of zomotherapeutic treatment is appended to this article. [T. L. C.]

14.—Arthur H. Buck reports a case of **lupus vulgaris** of 12 years standing treated with urea and cured. The patient was one who may be described as having been saturated with tubercle, and who possessed the tubercular diathesis to the large degree. His habits and diet have been opposed to the cure of any tubercular trouble, and during the process of treatment these conditions were not altered in any way. Lupus is perhaps the most intractable form of tuberculosis, especially to what are known as general or constitutional remedies. The lesion being on the surface, it was carefully watched and between April 23d and May 21st the disease seemed almost to melt away. No bad symptoms occurred even with urea 1 dr. t.d.s., but rather, the patient felt able to enjoy life for the first time for years. The treatment was begun with 30 grs. t. d., and gradually increased to a drachm. [T. L. C.]

15.—Thomas G. Lyon discusses the **ventilation of crowded places**. The recognized cause of air vitiation are decrease of oxygen, increase of carbonic acid, rise of temperature, excess in moisture, appearance of exhaled substances of unknown constitution. To effect good ventilation we must convey good air to all persons occupying a room, and must place no reliance on diffusion. This is the cardinal principle of ventilation for crowded rooms. He describes the special feature of the method devised by Mr. James Cadett and himself which is the employment of large inlets and outlets placed at opposite positions of a room. By this means the air is admitted at a low velocity, and is conveyed to and from all parts of the room. Diagrams of his system are furnished. [T. L. C.]

11. The Value of the X-Ray in Surgery. J. RUDIS-JICINSKY.

1.—Fenger, as the result of losing a patient from asphyxia due to sinking back of the tongue during sleep, following an extirpation of one-half the lower jaw, always leaves a loop of silk or silver wire attached to the anterior portion of the divided bone so that the nurse or patient may pull on it if dyspnea should arise. This precaution is sufficient only when the muscles extending from the hyoid bone to the maxilla are intact on one side. As the results of experiments on the cadaver he found that traction on the hyoid bone is far more effective than any other method for keeping the upper air passages open. When all the muscles running from the jaw to the tongue and hyoid bone are removed the author recommends passing a loop of silk around the body of the hyoid bone through a small longitudinal incision. The ends of the loop are left long enough to permit of manipulation by the operator or anesthetizer during the operation. At the close of the operation the loops left in place are attached to a plaster-of-Paris cast loosely covering the field of operation, with traction on the hyoid bone sufficient to prevent any sinking back of the larynx and epiglottis. The loop is allowed to remain for three or four days, until the patient is able to breathe freely with the head in any position. [F. T. S.]

2.—Bartlett reports two cases of **trifacial neuralgia** in which he removed the Gasserian ganglion intact, with a successful result in each case. The peripheral procedures for tic douloureux have proven of very doubtful benefit. Section of the sensory root, as proposed by Horsley, is scarcely less dangerous than ganglionectomy and the posterior root regenerates from the ganglion, so that we have but one course left to pursue in these operations, namely, removal of the ganglion. The indications for this operation are the involvement of more than one branch of the fifth nerve, the presence of pain in an area which receives its nerve near the latter's point of exit from the skull, paroxysms which are not the expression of constitutional or cerebral disease, and the failure of all other therapeutic measures. Bartlett's cases were operated upon by the Cushing inferior temporal method. The first patient was 60 years of age and had suffered for 17 years. All the teeth on the affected side had been extracted and the infra-orbital nerve removed. For four weeks after operation there was complete paralysis of the muscles innervated by the third, fourth and sixth nerves. This disappeared in the course of three weeks and a small ulcer of the cornea appeared, which finally healed. The second case was a woman aged 50, who for many years had been a victim of toothache on the right side. All the branches of the nerve were affected. Motor derangement of the eye was identical with that observed in the first patient, but the cornea remained intact. He quotes Tiffany, saying that "recurrence after a known removal has not been reported." Of 95 intra-cranial attacks on the trigeminus, according to Marchant and Herbert, in but 15 was the ganglion completely excised. Of 100 recent extirpations, according to Carson, but 11 resulted in death. [F. T. S.]

3.—Sidney Schwab reports on the pathology of the ganglia removed by Bartlett, and reviews the literature on the subject. He has collected the reports of 20 ganglia ex-

amined after their removal for trigeminal neuralgia. In a few cases the ganglion was found to be normal. A second group showed evidences of neuritis and degeneration. The third group consisted of two cases and showed an interstitial inflammation. The fourth group composing the largest number of reports, shows nerve cell changes of various degrees of severity, the changes being less those of a primary cell affection than a secondary one. The presence of brain sand or concretions was noted in three cases. In a very few cases changes in the blood cells were noticed. In both of the ganglia examined by Schwab the nerve cells were pathologically altered, but in neither to such a degree as to consider them primarily affected. The definite changes which are found in acute or long standing parenchymatous nerve cell affection were missed in these cases. Neuritis and atrophy were probably present in both cases in spite of the failure of the Van Gieson stain to prove their existence. Brain sand was found in the second case. He concludes that trigeminal neuralgia is not a definite disease but merely the symptom of various processes affecting the fifth nerve anywhere in its course from the periphery to the ganglion. It is probable that disease of the nerve cells does not exist as a primary parenchymatous affection. He divides neuralgic affections of the fifth nerve into two divisions; the first is an ascending neuritis beginning at the periphery and having a tendency to ascend to the ganglion; the second is an interstitial inflammation, chronic and progressive, of the ganglion itself. He places the first ganglion examined in the first and the second in the second category. A third division is possible, that is, a central neuralgia or neuritis of the sensory root, as two cases have been reported. Wherever the process is located, removal of the ganglion must be the final means of relief. The sensory root, if diseased, can only degenerate to the terminal ends of the neurons involved, and following the law of secondary degeneration the process must stop. Pathological processes in the brain itself, unless due to pressure, cause no pain, and as the Gasserian ganglion contains the cells of nutrition of the sensory root its removal will place this nerve outside of the realm of active symptomatology. [F. T. S.]

4.—Meyer reports a case of **osteoplastic amputation of the arm** at the junction of the middle and lower thirds according to the method of Hier for epithelioma of the forearm. After making the flaps the periosteum was pushed back for about a quarter of an inch and a bone flap sawed with the convexity toward the medullary cavity. As the saw approached the periosteum at the upper end of the bone flap it was removed and the remaining portion of bone broken through. The periosteum was now further stripped back from the humerus and the shaft of the bone sawed off in a curve with the convexity upward. The bone flap was now swung into place, filling the concavity in the end of the shaft and sealing the marrow cavity. It was impossible to suture the periosteum of the bone flap to the surrounding tissues because the periosteum was so easily torn. The patient secured a very good stump. Meyer describes a specially constructed bow-saw which he has devised for osteoplastic work. [F. T. S.]

5.—Mixer reports a case of **laceration of the spleen** in a man 25 years of age who was struck by the driving wheels of a locomotive. He was shocked, had vomited, and the abdomen was tender and rigid, and there was dullness in both flanks. At operation a piece of ruptured spleen was found free in the abdominal cavity. The remainder of the spleen was hanging by a few shreds of tissue and was removed without ligation, the splenic artery and vein being tied later. He reports a second case, a girl aged 10, who was run over by a heavy wagon. The abdomen was tender, and she passed a quantity of bloody urine. A lumbar incision exposed an infiltrating hemorrhage in the perinephritic tissues and a rent in the peritoneum. A portion of the kidney was found near the stomach, the remaining portion was almost completely torn from its pedicle. The vessels were ligated, the abdomen washed out, and the wound partially sutured and packed with gauze. Both cases recovered. [F. T. S.]

6.—Frazier reports a successful case of **epioplexy for cirrhosis of the liver**. The patient had been tapped five times, a large quantity of fluid being withdrawn each time. An attempt was made to perform the operation under local anesthesia but the pain was so great that ether was administered. Since the operation the patient has been tapped twice, once on the 13th day, and again on the 36th day. Since the last tapping there has been no reaccumula-

tion of fluid and the patient has gained rapidly in strength. Frazier says that but 14 cases have been reported in literature. Excluding those in which there was defective technique, an error of diagnosis, and those in which operation was contraindicated, but eight remain. Of these none died, one is living and unimproved, one living and improved, and six living and free from ascites at periods of three, four, six, 24, 24 and 26 months respectively. The cases for operation should be carefully selected. A case presenting the following conditions is a fit one for operation: (1) cirrhosis of the liver; (2) active liver cells; (3) utterly hopeless cases in which medication and paracentesis give no relief, (4) and when there are no reasonable contraindications. [F. T. S.]

7.—Ross reports two cases of **angina Ludovici**. The first case developed from a necrotic wisdom tooth. Within 12 hours the symptoms were so marked that operation became imperative. The second case suffered with tooth-ache for four days, when the submaxillary region began to swell and dyspnea asserted itself. An incision was made into the edematous sub-lingual tissue, relieving the dyspnea for a time. The next day the swelling extended upward to the zygoma and down to the mid-sternum. Under chloroform the abscess was opened by an incision through the muscles forming the floor of the mouth. During the operation the patient suddenly ceased breathing, necessitating an immediate tracheotomy. On the fifth day a secondary abscess on the right face was opened. As a result of the inflammation of the larynx aphonia resulted. Both patients recovered. [F. T. S.]

8.—Owens reports three rare complications of **hip-joint fractures**. The first was in a young adult who had fallen 22 feet, striking on his right foot. The leg was inverted and a rectal examination revealed a prominence of the floor of the acetabulum on the injured side. The skilgram revealed a fracture of the neck and of the rim of the acetabulum with a **subluxation** of the head of the femur. The second case was an old man who had sustained a fracture of the neck of the left femur. He was never able to flex the left foot upon the leg although the ankle and knee-joints were involved. This doubtless was due to a **paralysis of the external popliteal nerve** from pressure of the adhesive straps and bandage. An apparatus was devised to hold the foot up, thus facilitating his walking. The third patient was a man aged 73 with a fracture of the neck of the right thigh bone. On the 64th day after injury the symptoms of **pneumitis** appeared in the uninjured leg. When this had subsided and after the patient had been up for several days the right leg was similarly attacked. [F. T. S.]

9.—Paul reports and analyzes fifty-four cases of **fracture of the pelvis**. He emphasizes the fact that in some cases local tenderness but not mobility or crepitus is all that can be found antemortem. The cases reported show a mortality of 50 per cent. A table giving the cause, diagnosis, complication, operation and result of each case is appended. [F. T. S.]

10.—Ehrenfest describes an instrument for **tightening knots during vaginal operations** where the fingers can be used with great difficulty. It consists of two levers attached by means of a hinge resembling a glove-stretcher. On the top of each lever is a groove to admit each end of the ligature. Below the hinge is a mechanism which automatically holds fast the two threads. After tying a knot as tightly as one can with the fingers the tips of the instrument are introduced between the two ends of the ligature so that each is contained in either groove at the tip. The ends of the ligature are now pressed in the automatic mechanism below the spring and the handles of the instrument approximated. This separates the tops of the levers and so fixes the ligature. The instrument is not practicable for catgut since the fixation blocks destroy the integrity of such soft material. [F. T. S.]

11.—Ruls-Jelinsky says the X-ray shadow is treacherous and may be easily exaggerated or changed by position, so that it is necessary to have the subject in a certain definite position and have more than one skilgraph taken from different points in each case. It is also of great value to compare the picture of the injured parts to that of the normal one. Four cases are reported to demonstrate the value of the X-ray. One patient had an injury of the hip which after five years of treatment for coxalgia was demonstrated to be a dislocation of the head of the femur. Another case was diagnosed as appendicitis, later as

carcinoma of the liver, and finally as simple jaundice. She was submitted to five lengthy exposures with a negative result. The sixth one lasted 50 seconds, the plate revealing two gall stones. The diagnosis was verified by operation. The third patient had suffered from headache on the left side for six years following a sunstroke. The X-ray revealed a large, epidural clot under the parietal bone on the painful side. The clot, amounting to four ounces, was removed and recovery followed in three weeks without any complication. The last case reported was variously diagnosed as primary lateral sclerosis, acute myelitis, and spinal meningitis. On X-ray examination destruction of the bony substances of the vertebrae was demonstrated, the changes being tubercular without doubt. The pictures of the above cases are included in the report. [F. T. S.]

6. The Surgical Treatment of Prolapse of the Uterus. FRED BOWREMAN JESSETT.

1.—During the past 15 years Shield has treated 42 cases of goiter surgically and a number of other cases medically. The medical treatment that he has adopted has consisted of the administration of 3 grains of potassium iodide with one minim of tincture of iodine. The usual vehicle has been the tincture of gentian and the drugs have been given after meals. Sometimes 3 minim doses of tincture of iodine have been used, but such large doses need to be carefully watched, and if signs of iodism appear they should be stopped. Thyroid extract in full doses has given good results and in one case hydriodic acid has been used. Sea air is a most important adjunct to the iodine treatment. The author believes that it is possible for small goiters to disappear entirely under this treatment and the symptoms of large, formidable goiters may be much ameliorated. He has little confidence in the efficacy of such local measures as the injections of iodine or mercury perchloride into the parenchymatous forms of goiter. Any local inflammatory action set up by these agents most seriously prejudices the chances of the patient in any needful subsequent operative proceedings. The same objections do not apply to the external application of the red iodide of mercury ointment, although no great benefit has been seen attending its use. In a considerable number of cases of goiter, medicinal treatment of the kind described quite fails to check the growth of the tumors or to diminish their size and operative treatment has to be adopted. A study of the 42 cases reported, conclusively shows that the operative treatment of goiters that are still small, and particularly if they are movable, if properly carried out, is free from any special risk. On the other hand, operations on goiters of large size, of long growth and with extensive deep connections are perilous in the extreme. Out of the 42 cases, 6 were adenomatous, 5 contained cysts and one, an exophthalmic goiter, was operated upon on account of dyspnea. There was one death from hemorrhage. The tumor in this case was enormous and showed evidences of carcinomatous change with extension to other parts. In one advanced case, the operation was abandoned on account of the important structures that were involved in the growth. There was no instance in which sepsis occurred. The majority of the adenomatous tumors were in the isthmus of the thyroid gland and diagnosed by their marked mobility. The differentiation between adenoma of the thyroid and cyst of the thyroid is very difficult, and indeed, grave consequences may result from cutting into goiters for the enucleation of supposed adenomatous tumors that do not exist. When cysts are of small size they may be opened, painted with carbolic

acid and packed with iodoform gauze. Hemorrhage is a troublesome complication that is likely to arise in such a case. The author describes briefly the steps of his operation. Like so many English surgeons he prefers chloroform for the anesthetic. He believes that the operation of the removal of one lobe of the thyroid gland with the isthmus is practically always followed by atrophy of the remaining lobe. [J. M. S.]

2.—The capillary reflux is the flowing back or reflux of the blood into the capillaries of a portion of the surface of the skin rendered anemic by pressure. Haig believes that the rate of this reflux is a measure of the quantity of uric acid in the blood because the uric acid controls the capillary circulation. In order to observe this phenomenon it is necessary to apply to a known surface, a known pressure for a definite time, and to measure very accurately the time which the blood and color take to make a complete return into the anemic area. The surface and the pressure are measured by an instrument known as a capillary dynamometer. It is necessary that the hand should be about the ordinary temperature of the body, as cold diminishes the solubility of uric acid in the blood stream, and thus increases the precipitation of the colloid that blocks the capillaries and slows the reflux. Heat, on the other hand, increases the solubility of the uric acid in the blood stream, diminishes the colloid blocking of the capillaries and quickens the reflux. Again, the hand should be at about the level of the heart, for the greater the column of blood above the anemic area the quicker will be the reflux. Similarly, a tight sleeve, a band around the arm or a thrombus in a vein will cause serious congestion and quicken the influx on the distal side of the obstruction. When the patient is in the horizontal position, the best plan is to take the reflux on the front of the chest at the level of the heart. The author has adopted 15 ounces pressure for 6 half seconds as the normal for making these tests. The quantity of uric acid in the blood is greater in the morning than it is in the evening. Therefore, the capillary reflux should be greater in the morning than it is in the evening. Blood pressure shows exactly similar fluctuations and, if the condition of the heart is known to be physiological, the blood pressure can be inferred with considerable accuracy from the capillary reflux. Large fluctuations of the capillary reflux such as that of Bright's disease, in which it is slow, and in fever, in which it is quick, may be recognized by anyone by pressure made by the point of the finger. The capillary reflux is quick in fever because the blood is cleared of uric acid; in fever with dyspnea, however, the blood is not cleared of its uric acid and the reflux is not quickened and the blood pressure is not reduced. When a patient takes a course of salicylate medication the capillary reflux is not affected so much in the morning as in the evening at first, because the solvent power of the salicylate for uric acid or its component parts is greater in the evening, when the alkalinity of the blood is least, just as it is greatest in fever when the alkalinity of the blood is greatly diminished, and is at its least in chronic conditions of debility and asthenia when the alkalinity of the blood is not all diminished. Hence, salicylates are most useful in acute conditions with high fever, but may be almost of no use in chronic conditions with debility and failure of nutrition; in these latter conditions they are not solvents of uric acid to anything like the extent that they are in acute fever with diminished alkalinity of the blood. By a study of the capillary reflux the smaller effect of an alkali may be demonstrated.

[J. M. S.]

3.—The springs of Nauheim are 6 in number, 3 used for bathing and 3 for drinking. The chief ingredients of the water of the springs used for drinking are chlorides, small quantities of iron and lithia. The bathing waters are rich in carbonic acid gas. This water is received into tanks, which are open to the air so that much of the gas escapes, and iron and lime, which are held in solution by the gas, are precipitated out. The course of baths is begun with water drawn from one of these tanks containing an amount of gas less than that present in the water direct from the springs. The arrangements permit the water to be heated and allow of the addition of any desired quantity of plain water. This is the thermal sool-bad. In the outskirts of the town there are salt works in which the common salt is crystallized out of the bathing water. The remaining dark-brown, very pungent tasting liquor, called *mutterlaug* or mother-lye, is kept for adding to the bath

to strengthen it. Some of the water is evaporated to dryness in which state it forms large, dirty-brown masses with a crystalline fracture. This is **Nauheim bath salt** and is suitable for artificial baths. Pipes are led from the springs before they reach the surface to the bath-tubs so that the water may be turned on foaming and bubbling directly from the spring in the earth. This is the effervescent or **sprudel-bad**. In one of the bath houses the tubs are so arranged that by the removal of a plug an overflow is provided at the top of the bath. When the bath is full the patient steps in and lies down while the water foams in along the floor of the bath and escapes at the top. This is the current or **strom-bad**. If a patient whose heart presents evidences of dilation with muscular failure takes a sprudel bath, at the end of a minute he is very uncomfortable, but in one minute more the look of anxiety is gone, the color is improving, the breathing is deeper and easier, the pulse is fuller and firmer. This improvement goes on until the patient is very comfortable. As soon as he steps out and is wrapped in a hot bath-sheet his skin is uniformly pink wherever it has been covered by the water. This patient, after a moderately brisk rub with the warm bath-sheet given by the bath attendant, dresses slowly and walks home to sip his bouillon and to take his midday rest. Suppose the bath to be at the temperature of 91°F., on stepping into it the immersion in cold water will contract the arterioles of the skin and this increase of peripheral resistance produces the temporary discomfort. During the rise of bloodpressure in this period of vasoconstriction there is risk of sclerosed vessels yielding, or even of cardiac shock. In practice, however, no patient is ever thus plunged into such a strong bath, and these effects are almost entirely discounted by beginning the course with baths at a higher temperature and by dilution of the water. Subsequently the strength of the bath is gradually increased. After the period of vasoconstriction the specific constituents of the water begin to act upon the skin, the vasoconstriction yields rapidly, the surface arterioles widen, the skin is everywhere flushed with a fresh tide of blood, and the patient is aware of it by the feeling of comfort and warmth that flows over him, sweeping away the chilliness of the first moment of immersion. There are 2 effects, then, of Nauheim waters: (1) the chemical action on the skin producing vasodilation, and (2) the reflex nervous action of the heart. By the first the work of the heart is lightened, by the other its ability to do work is increased. The effects of the Nauheim waters on bloodpressure are, in brief, as follows: The moment the patient steps into the bath he is affected by the temperature of the water, perhaps reinforced slightly by a constricting effect of the saline ingredients, the bloodvessels are contracted, the bloodpressure is raised, the pulse is very markedly slowed and a strain is thereby thrown on the heart. These effects are only momentary and quickly yield to the real effects of the specific ingredients of the waters. The capillaries dilate, the bloodpressure falls and the pulse rate rises slightly. But though the peripheral resistance goes on diminishing by increasing vascular dilation, the fall in bloodpressure ceases to keep pace with it and so also does the rise in pulse rate, because the later effects of cardiac stimulation begin to operate. The bath, therefore, does 2 things: (1) It effects a complete change in the distribution of the blood and thus diminishes the resistance the heart has to overcome, and (2) it stimulates the heart to more energetic contraction, while diminishing its pace. The baths are useful (1) in the diseases of general nutrition, such as scrofulosis, rachitis, chronic exudations and residuary effects of inflammation, hyperplasia of the lymph-nodes, chronic metritis, oophoritis, prostatitis, mastitis, and the like. (2) In cases of muscular weakness of the heart due to or originated by physical overstrain or the effects of prolonged overwork or the result of influenza or some similar toxic influence or cases of dilation without hypertrophy and without heart lesion. (3) In cases of valvular disease of the heart in which compensation has failed or has never been properly established. (4) In cases of cardiac neuroses. While the author does not believe that true angina and atheromatous changes in the vessels are necessarily contraindications to the treatment, he advises great caution in its application to any case of this description. (5) In cases of some other neuroses, such as tachycardia, exophthalmos and peripheral neuritis. Schott, in addition to the baths, uses the saline drinking waters and special exercises in his treatment of the patients that go to Neuheim. A description of some of these

exercises and instructions for making artificial Nauheim baths at home are included in the article, but are too detailed to be incorporated in the limits of an abstract. [J. M. S.]

DEUTSCHE MEDICINISCHE WOCHENSCHRIFT.

May 23, 1901.

1. The Demonstration of the Presence of Sugar in the Urine. A. CIPOLLINA.
2. The Treatment of Uric Acid Diathesis. DETERMEYER and BUETTNER.
3. Further Communication Concerning the Germ of Vaccinia and Variola. M. FUNCK.
4. Pulsating Pleurisy. J. KULLMANN.

1.—Cipollina has investigated in Salkowski's laboratory the value of the methods of using the phenylhydrazin test for sugar described by Lamanna, Kowarski and Neumann (these tests were given in abstract in the *Philadelphia Medical Journal* last year). He decides that the only one that gives sufficiently delicate results is that of Neumann, and that this is sometimes negative in urines of high specific gravity containing as much as 0.5% of sugar. In general, however, it is an excellent test, but one must never consider the result negative unless no crystals have formed after one hour. As a rule they form much earlier, after a few moments, but occasionally they may appear only after about one hour. A modification of Lamanna's test proved quite as delicate as Neumann's, however, and had the advantage that special tubes are not required as they are with Neumann's method. This is carried out as follows: Five drops of pure phenylhydrazin are placed in a test tube, $\frac{1}{2}$ c.cm. glacial acetic or 1 c.cm. 50% acetic acid and 4 c.cm. of urine added. The mixture is boiled about one minute, being constantly shaken. Four or five drops of caustic soda solution (specific gravity 1.16) added, the fluid being kept acid, however, boiled again for a moment and then cooled. If by this or Neumann's method sheaves or rosettes of crystals are formed, one may say positively that sugar is present. [D. L. E.]

2.—The paper refers to the influence of a special spring water at the home of the authors on the excretion of uric acid and phosphates. The authors found that it increased the output of both substances in a gouty subject, but had no effect in healthy persons. They therefore consider the water useful in gouty diathesis. [D. L. E.]

3.—Funck replies to Podwyszozy and Mankowski (*Deutsch. Med. Woch.*, April 27th) that his complete report will soon be out and will substantiate his statements. He admits that one can readily find degenerated glands and epithelial cells in vaccine fluid, but insists that the bodies described are different, though easily confused with these. They, however, do not stain with Sudan as Scarlet Red. More complete descriptions with illustrations will soon appear in the *Centralblatt für Bacteriologie*. [D. L. E.]

4.—The case was chiefly of interest because it was one of serous pleurisy. Pulsating empyema is well known and not extremely uncommon, but apparently only two uncomplicated cases of pulsating pleurisy have heretofore been described. This case occurred in a man 40 years old. The illness had lasted three months, 2 weeks before admission 1600 c.cm. of clear fluid had been withdrawn. He had all the usual signs of a large effusion in the left thorax, the heart was pushed to the right of the sternum and on the left side of the chest one saw and felt marked pulsation. There was slight pulsation to the right of the sternum also, and a mass which pulsated strongly was seen and felt for three fingers' breadths below the left costal border. The latter was evidently produced by pressure of the diaphragm downward by the large effusion. Kullman believes that Traube's explanation is sufficient only in left-sided cases. This explanation refers the pulsation to good transmission of the heart movements through the air-free lung, the pulsation becoming more apparent when the intercostal tissues are lax. Kullman considers it important to see whether the altered character of the heart movements and the relation of the heart to the fluid in the individual case are not of still greater importance than the above factors and whether when the exudates causes marked distension, the resistance of the mediastinum does not overcome that of the thoracic wall so that in its efforts to contract the heart it is driven toward the wall of the thorax. [D. L. E.]

WIENER KLINISCHE WOCHENSCHRIFT.

June 27, 1901. (XIV Jahrgang, No. 26).

1. The Influence Upon the Fetus of Treating Syphilitic Mothers. G. RIEHL.
2. A Peculiarly Localized Arthropathy, in a Case of Syringomyelia with Genital Hypoplasia. G. HOEDDMOSER.
3. Two Cases of Tumor Thrombosis of the Inferior Vena Cava. KARL STERNBERG.

1.—Riehl has experimented upon 29 pregnant women with secondary syphilis. From a full review of the literature, it seems certain that, with recent syphilis in the mother, treatment has but a faint chance of causing the birth of a healthy child. Beside the general treatment of the mother, Riehl inserted one gram of unguentum hydrargyri in the vagina daily, keeping it in by a tampon. He begins these mercurial applications just as soon as pregnancy is even suspected. No symptoms of local irritation or of stomatitis were ever seen. Out of 33 syphilitic mothers, there occurred one abortion; three premature deliveries; two still-born infants at term; two syphilitic infants at term; and 29 normal infants at term. In all, a mortality of 12%, a morbidity of 21%. From this Riehl believes that a favorable prognosis for the coming child can be obtained by vaginal treatment of the pregnant mother. In his private practice, the results were even better. [M. O.]

2.—Hoeddmoser reports a case of syringomyelia in an imbecile of 59. The symptoms of syringomyelia first appeared in one arm 17 years ago. Now he has all the main signs of syringomyelia, and testicles the size of peas. The acromio-clavicular joint opened spontaneously, showing an upward luxation of the clavicle. This is well shown by a Röntgen photograph. It healed about a month later. In all the literature, only 95 arthropathies occurred, 29 of them in the shoulder. While they are seen as often in tabes as in syringomyelia, no case of luxation of the acromio-clavicular articulation has ever been recorded before. That this could develop was due to the influence of the syringomyelia upon the trophic nerves, causing atrophy of the muscles. Then the luxated end of the clavicle led to perforation by pressure. The congenital hypoplasia of the testicles may help to account for the occurrence of syringomyelia, as gliosis is prone to appear in subjects with anomalies of development. [M. O.]

3.—Sternberg reports two cases of tumors occluding the inferior vena cava, which he found in performing autopsies upon old women aged respectively 60 and 70 years. In the first case, a suprarenal epithelioma filled the entire vein and reached to the right heart; in the second a carcinoma of the liver had grown through the hepatic and portal veins into the right side of the heart. A few similar cases were found in the literature. Few metastases occur, generally into the lungs only.

[M. O.]

JOURNAL DES PRATICIENS.

July 6, 1901. (15me. Année, No. 27).

1. The Treatment of Neurasthenia. MAURICE DE FLEURY.
2. The Society for Sanitary and Moral Prophylaxis. ALFRED FOURNIER.

1.—Will be abstracted when concluded.

2.—There has lately been formed in France a society directed against alcoholism, tuberculosis, and syphilis. That such an association was needed to combat the ravages of syphilis is shown by its frequency (13 to 18%), its gravity, both for the individual and society, and the insufficiency of the actual prophylaxis. This society hopes to assemble progressive men in all professions to examine into the subject, to present the question to the public, its dangers and their solutions, to acquire a moral power by which they might impress their opinions upon the government, and to prepare for the future dispensaries, schools, asylums, etc. to combat both syphilis and its main cause, prostitution. The means of action of the society will be moral or religious; administrative, for the regulation of prostitution; and medical, for the prophylaxis and treatment. Fournier believes that a special dispensary should be established where case-histories are kept and medicine is given gratis, where the poor sees the physician alone just as the rich man visits him in his office. [M. O.]

June 21, 1901. (15me. Année, No. 25).

1. The Three Hypertensions. HENRI HUCHARD.

1.—Huchard discusses clinically and therapeutically the three hypertensions, arterial, pulmonary and portal hypertensions. Increase in the arterial tension, from the cardiac impulse, is shown physiologically by excitation of the cardiac nerves, and clinically by ventricular weakness. The main cause of the increased tension, however, is increased tonicity of the arteries, which is in turn due to increased resistance in the peripheral circulation. Heart trouble which begins in the heart generally shows hypotension, while that which commences in the arteries causes hypertension. For the latter condition, Huchard advises hypotensive treatment, in the condition described as presclerosis, in angina pectoris, stenocardia, uremia, gout, interstitial nephritis, etc., all heart conditions of arterial origin. The great cause of these conditions is excessive meat diet. Erythrol tetranitrate will be found of great use in these affections, with massage, and a diet of milk and vegetables. Organotherapy may eventually be of aid in treating these diseases. Pulmonary hypertension exists with mitral disease, especially stenosis of the mitral valve. Aortic and pulmonary hypertension may be present together, causing arrhythmic palpitation. Then the same hypotensive treatment used for arterial hypertension will prove effectual. Portal hypertension begins in the veins, and is found physiologically with anemia, arterial hypotension, and toxic symptoms. Clinically the condition occurs with phlephlebitis, atrophic cirrhosis of the liver, uncompensated heart lesions, etc. It may be acute, subacute, or chronic. It is occasionally noted at the menopause, and may cause hemorrhages and obesity. Abdominal massage, and a diet of milk and vegetables constitute the treatment. Digitalis and theobromin may aid. These conditions of hypertension may co-exist; then the prognosis becomes serious. Each one of them must be well treated, and quickly, especially the last, to prevent the development of arteriosclerosis, and heart lesions, later. The best means of treatment is the hypotensive method, states Huchard. [M. O.]

REVUE DE CHIRURGIE.

July, 1901. (21me. Année, No. 7).

1. Perforating Wounds of the Abdomen. EUGENE VINCENT.
2. Trephining for Ancient Injuries of the Skull. MAURICE PERAIRE.
3. Vascular Tears in Fracture of the Clavicle. E. GALLOIS and P. PIOLLET.
4. The Study of Antrectomy. OLIVIER LENOIR.
5. The Accidents Attending the Eruption of the Wisdom Tooth. MOTY.
6. Scapulo-humeral Arthrodesis. BOTHEZAT.

1.—Vincent believes that no absolute rule can be formulated for the surgical treatment of penetrating wounds of the abdomen. He advises the expectant treatment, when the wound is due to fire-arms; when due to the kick of a horse, laparotomy is best at once; if due to pointed instruments, wait for signs of hemorrhage, torn intestine, etc., before operating; if due to instruments with sharp blades, exploratory laparotomy will generally be indicated. Besides, whenever internal hemorrhage is suspected, laparotomy should be performed immediately. Vincent reports three cases. In the first, a knife entered the stomach. The incision was enlarged and the stomach wound sutured. The second patient fell from a tree, landing on a stake, 45 cm. which, breaking off, entered the iliac fossa. This was removed and ice was applied. Three days later an incision was made in the lumbar region, a sero-sanguineous collection evacuated, touched with the thermo-cautery, and the sinus allowed to heal. A month later he was well. In the last case, an omental hernia followed the penetrating abdominal wound. The omentum was resected after ligation, and returned into the abdomen, the ligature ends serving as drainage. From these results, Vincent advises the expectant treatment always. For as soon as any bad sign appears, laparotomy can be done. [M. O.]

2.—Peraire reports two cases in which he trephined, for injuries to the skull received 7 and 12 years before. In the first case, headache, fever, insomnia, loss of memory, inability to work, nausea, vomiting, and weakness of the legs persisted from the time his head had been struck. An

abscess was discovered by trephining, evacuated, and recovery followed. In the second case a revolver bullet had remained for twelve years in the brain. Then a circumscribed meningo-encephalitis developed about it. Though the bullet was shown by Röntgen photographs, the point for trephining was found by the symptoms. The bullet was removed and he recovered. [M. O.]

3.—Will be abstracted when concluded.

4.—Will be abstracted when concluded.

5.—A series of morbid phenomena may be observed before, with, or after the eruption of the wisdom tooth. These accidents appear about the twentieth year, and consist of pain, edema of the gums, enlargement of the parotid, infiltration, abscess formation, persistent fistulae inflammation of the dental canal, trismus, and symptoms of paralysis. The mild form is common, and is only diagnosed after the appearance of the tooth. In the severe form, epithelial debris from the tooth remains included in the alveolus. Symptoms are marked, and the pus formed is offensive. No necrosis occurs, however. It may be acute, or may become chronic. The diagnosis is easy, tumors alone having to be differentiated. If the tooth remains in the gum, a dermoid cyst may develop. Or the tooth may become carious, without ever appearing, and will then form an infected abscess, with necrosis. Very grave cases may somewhat resemble thrombosis of the jugular vein, without the cerebral symptoms. Odd cases have been observed, with osteomyelitis, osteitis, etc. The eruption of the wisdom tooth in the upper jaw is always less severe than in the lower jaw. If the accidents are mild, the treatment is mild. When the accidents are severe, the tooth must be extracted, and the abscesses, fistulae, etc. treated. The extraction of these large teeth, with their double roots may be very difficult. Even when the tooth is not visible, it must be found and extracted. Beside gargles, sublimate compresses, etc., incision of the abscess, irrigation, curettage, drainage, etc. will be necessary. All these phenomena are due to epithelial inclusion; and as the dental canal is invaded the accidents become more severe. Extraction of the tooth is always advised. [M. O.]

6.—Scapulo-humeral arthrodesis for paralytic luxation of the shoulder was first performed by Albert in 1879. Paralytic luxation of the shoulder passes through four stages, a prodromal stage, with fever; a stage of paralysis, total or partial; a stage of partial recovery; and the final stage of the paralysis remaining. Atrophy of the muscles follows, and the luxation develops. Surgical treatment is needed to improve the condition. This is always the same, whether the cause be cerebral, spinal, or peripheral. The paralyzed arm is smaller and shorter than the healthy arm; the shoulder is higher than the well shoulder. The condition exists in five clinical forms: affecting the deltoid alone, or with the external rotators; the deltoid; the external rotators, and the triceps; all the muscles of the arm and the supinator longus; all the muscles of the arm and forearm; and total paraplegia. Electrical reactions are wanting. Surgery offers apparatus and operations for this condition. Apparatus, however, does little good, and is a great inconvenience. The most important operation is scapulo-humeral arthrodesis, which causes ankylosis with the head of the humerus fixed in the glenoid cavity of the scapula. The movements of the scapula are then used to move the arm. Thus abduction, flexion, and extension become possible. Scapulo-humeral arthrodesis is indicated when the paralysis will not yield to medical treatment, and when the muscles of the scapula, elbow and hand are normal. The first condition will be shown by electricity, for investigation and treatment, and by the age of the paralysis. If the muscles of the elbow are also paralyzed, arthrodesis of the elbow can be performed. The technique of the operation is simple. The incision is made anteriorly, the articulation opened, and the glenoid cavity cleaned; the head of the humerus is placed in it, and the wound closed. Muscles which were cut, are sutured. The arm is put into plaster for two months, and massage and electricity employed. Bothezat reports in detail five cases, three his own, with his own technique. Acute anterior poliomyelitis in infancy caused them all. The results were excellent. Movements were made possible and the progress of the muscular atrophy was stopped. Solid osseous ankylosis follows arthrodesis. [M. O.]

Special Article.

PROFESSIONAL OPINIONS OF PROMINENT SURGEONS REGARDING THE PRESIDENT'S WOUNDS.

In view of the absorbing interest, to both the profession and the public, of the President's case, we have obtained the following opinions from well known surgeons on its strictly scientific aspect. It is gratifying to note that there is practical unanimity of opinion on all the grave questions involved:

Dr. John B. Deaver stated that from the nature of the bulletins by which only he could be guided, he believed that the President will recover. He expressed his opinion as follows: "I think that more cases similar to the President's would be followed by recovery, if prompt surgical treatment at the hands of men with the capability of the President's surgeons were instituted. The greatest risk to which the President was exposed, barring hemorrhage, was that of infection of the peritoneal cavity. It is in these cases where procrastination, dilly dallying, the fear of assuming too much responsibility, in short, not having the courage of one's convictions, are responsible too often, I regret to say, when the surgeon finally prepares to repair the damaged tissue. If it is ever indicated to apply the expression "he who hesitates is lost," it is in cases of wound of the abdomen. We are not justified in questioning whether the wound is of a penetrating or of a non-penetrating character. In this day of aseptic clean surgery the immediate action to mechanically correct the damage done is the "*sine qua non*." The promptness with which incision into the abdominal cavity was made, revealing the injured viscus and the extent of the injury, the repair of the same followed by a flushing with sterile salt solution, and the immediate closure of the abdominal cavity, is putting into practice modern surgical art. The results in the President's case demonstrate the value of asepsis and not anti-sepsis.

Dr. J. B. Roberts stated: "From the information given by the newspapers, I believe that the President received a wound which would have been followed by rapidly fatal septic peritonitis, had early operation not been performed. It has been a source of much satisfaction that he has had the services of such well known and justly distinguished surgeons."

Dr. Joseph Price stated, "It is fortunate that a hospital in readiness and with the best modern appointments should have been in the immediate vicinity of the accident, and that prompt abdominal surgery was employed by from two to three of the best men in the country, all of whom have had excellent results in a prolonged practice, and all of whom have performed very complicated and successful work. It is also fortunate that the surgical ability of Buffalo was at home. Most of these operations result disastrously on account of the delay in waiting until the next morning. In this case the surgeons promptly sought perforation, cleaned and closed it, and determined the fact that other important viscera were not injured. There having been no hemorrhage from wounded vessels, probably settled the fact that the ball was innocent and buried in muscle, and therefore no attempt was made to seek or to remove it. As there is no evidence of splenic, renal or spinal injury, we could expect but one result in the hands of such men. The pulse of the President was rapid and the temperature a little high, which would, however, be explained by the extent and nature of the injury in a man of the President's age. The delay caused by sending to adjoining cities or educational centres for surgeons, commonly results disastrously. Promptitude was of paramount importance in this case as it is in similar ones. Again, the surgeons were prompted by their large and varied experiences and were not in the slightest degree influenced by the opinions of Sir William McCormac and Mr. Treves, as to the non-interference in gun shot wounds in the abdomen. Drainage was not necessary in this case. There had been no vomiting, the stomach was empty at the time

of perforation, and if the peritoneum was contaminated at all, the toilet was perfect. In the great work of Dr. Dalton, of St. Louis, about all the operations were performed in general hospitals, but were as prompt as possible. Early interference exceptionally results in death unless some injury be overlooked. Overlooking a perforation of the bladder, bowel or some other important organ is quite common. A few years ago my brother, Dr. M. Price, removed the right kidney for a gunshot wound involving both kidney and liver, hemorrhage having been quite copious from both organs. The kidney was removed and the liver wound carefully drained. In this case drainage was important; had it not been practiced, the results would probably have been disastrous and fatal. Drainage in the President's case was not indicated and would have delayed his convalescence had it been instituted. Large numbers of old soldiers carry large musket or rifle bullets in their muscles or in their bones. I know of three soldiers who are carrying bullets in the mastoid portions of their temporal bones or in the deep structures of their ears, all useful men. In Garfield's case there was an injury to his spinal cord and column as well as injury to large vessels resulting in aneurysmal complications. The injuries in the two President's cases are not at all similar. One could and was repaired by skilled hands, the other could not be repaired.

Dr. R. C. Norris stated, "Following with interest the course of the President's convalescence, the anxiety on account of his pulse particularly has largely disappeared now in view of the fact that symptoms of peritonitis have not developed, and at this day we can feel practically assured that it will not develop. Ability to take food by the mouth, free action of the bowels, his returning strength, cheerful disposition, ability to sleep, together with a steady improvement in his pulse and temperature warrant us to believe that his convalescence is assured. The medical profession should feel especially proud of this triumph of modern surgery, and while the greatest praise should be awarded to all the physicians associated in the management of the President's illness, the prompt and skillful work of Dr. Mann should not be lost sight of as the important factor in rescuing the President from certain death. It is of interest to note the rare good judgment displayed by Dr. Mann in not employing the gauze drain."

Dr. Orville Horwitz stated, "The promptness with which the President was treated saved his life. The fact that the surgeons treated him like any other patient with a similar wound and the skill employed speaks well for American surgery. That there has been no peritonitis shows the value of aseptic closure of the wound. I believe that the surgeons displayed excellent judgment in not continuing their search for the other bullet as no viscera other than the stomach were injured."

Dr. Henry R. Wharton stated, "Following the history of the President's case from the bulletins published by his physicians, I am led to believe that a favorable termination is likely. At present the moderate elevation of the temperature and pulse rate might point to the development of a superficial abscess but does not point to the development of peritonitis. It is probable, by this time, that the perforating wounds in the walls of the stomach, which were promptly closed by sutures, are healed and will cause no further disturbance. The bullet which is supposed to be buried in the muscles of the back is not likely to give rise to serious trouble. The favorable outlook of the case up to the present time seems to be largely due to the modern methods of surgical treatment carried out by the very competent staff of surgeons under whose care the President has been."

Dr. William B. Coley, of New York, stated, "The President's case furnishes new and striking proof of the soundness of the American method of treatment of gun-shot wounds of the abdomen. The brilliant successes of Kocher and Bull in 1883 and 1884 first brought the operation into prominence. American surgeons were the first to accept their teachings, while as late as 1890 two of the leading French surgeons made a vigorous attack upon what they termed the American method of treating shot wounds of the abdomen, and still advocate the old *laissez faire* policy. The same year, I made an analysis of one hundred and sixty-five cases treated by operation, the majority by American surgeons. This analysis showed a mortality of only sixty-seven and two-tenths per cent., in place of the mortality of about ninety per cent. by the old methods. Of twenty-four cases of wounds of the stomach, there were six recoveries. In

forty-eight fatal cases, death was due to peritonitis. In twenty-five cases the average time of death in the fatal cases was twenty-six hours after operation. In only one case did death occur after five days, and this was a case of wounds of stomach, liver and kidney. The enormous importance of early operation is shown by the fact that, of the cases operated upon during the first twelve hours, forty-three and six-tenths recovered, while only twenty-two and seven tenths recovered of those operated upon during the second twelve hours. The fact that the President was operated upon almost immediately after the injury by a very skillful surgeon, combined with the most important fact that the stomach was practically empty, renders the prognosis most hopeful. The fact that he has already progressed favorably for five days, makes the hope of recovery almost a certainty. The further experiences of the last decade, based upon a much larger number of cases treated by operation, confirms the conclusions that I drew in 1890. These were, first, exploratory incision in the region of the wound to see if it be penetrating; second, if penetrating, immediate median laparotomy; third, signs of peritonitis, if present, while lessening the chances of recovery, do not contraindicate operation."

Dr. Christian Fenger, of Chicago, stated, "It is a satisfaction that this life, so precious to us and to the whole civilized world, has been saved by a foundation laid by two of our own immortals. It was the labors of Senn and the late Charles T. Parker that revolutionized the treatment of internal wounds. A perfectly typical and I might say, ideal handling of the President's case was made possible by the exposition hospital facilities and by the mental superiority of the august patient who put himself unreservedly into the hands of able men who did not hesitate an instant to assume the responsibility of prompt action on the lines of most advanced knowledge of rational, intelligent surgery. The masterly technique of Mann, the efficient assistance and counsel of Mynter and Reswell Park, also masters in abdominal surgery, the splendid handling of the anesthetic by Wasdin, the after treatment, so ably conducted by these gentlemen and Rixey, contributed to a result for which not only the nation, but the whole world, is at this moment profoundly thankful. The enormous burden of responsibility that had to be borne was much lightened by the wise counsel and assistance of McBurney. Of inestimable value to all concerned was the clearheadedness of Secretary Cortelyou, who, without hesitation, which in this case would have been fatal, made it possible to save the President's life by prompt decisive action. Irrespective of this happy result, we have to congratulate ourselves that this celebrated case has been handled throughout in so masterly a way, that it will stand forever as an example of perfect, scientific surgery."

Dr. Arpad G. Gerster, of New York City, stated, "The President will recover. His recovery will be due to the prompt assent he gave to the energetic proposal of his medical advisers, and last, but not least, to the excellent surgery practiced on him. The surgeons that are saving the life of President McKinley could probably have done the same for Garfield, because they knew and practiced the same methods in 1881 they are employing so successfully to-day, but they were young men then and the gray hairs at the head of the profession did not practice modern surgery."

THE PRESIDENT'S CONDITION.

FRIDAY NOON, SEPTEMBER 13, 1901.

An unfavorable change having unfortunately developed in President McKinley's condition just as we are about to go to press renders the prognosis very dubious. The opinions quoted above however are so instructive, and teach so much from a purely surgical standpoint that they are well worth recording. It is still to be hoped that the skill of the attending physicians may preserve the life of the Chief Executive of the Nation.

Society Reports.

CANADIAN MEDICAL ASSOCIATION.

Reported by

DR. GEORGE ELLIOTT,

Our Special Correspondent

The 34th Annual Meeting of "The Canadian Medical Association" opened at Winnipeg, Manitoba, on the morning of the 28th of August and continued for the two following days. There were in attendance over 175 members from all parts of the Dominion, the second largest gathering in the history of the Association; and the meeting itself has been pronounced the most successful of any yet held under the auspices of this Association. There were several visiting doctors from the United States.

Dr. H. H. Chown of Winnipeg, the President, occupied the chair, while Dr. N. F. G. Starr of Toronto, discharged the duties of Secretary.

In the absence of Chief Justice Killan Dr. J. H. O'Donnell, one of the oldest practitioners in the West, delivered the address of welcome. He referred to the conditions present in 1869 when Winnipeg was an outpost of civilization, and gave interesting references to Drs. Cowan, Curtis J. Bld., Dr. Beddom, and Dr. Bund who were already in the West when Dr. O'Donnell moved there in 1869. His address was very much appreciated by the members of the Association.

Dr. R. W. Powell of Ottawa, the past President of the Association, then introduced Dr. H. H. Chown, the President-elect, to the Association.

Dr. Chown on rising to reply was received with hearty cheers, testifying to the high esteem in which he is held by his fellow-practitioners through the Dominion. He briefly thanked the Association for the honor they had conferred upon him at the meeting in Ottawa one year ago.

Dr. Starr, the Secretary, presented his Annual Report. It referred to the meeting at Ottawa last year, to the attendance of 153 members, which was an increase over former meetings in that city, to Dominion Registration and to the formation of a Physicians' Protective Association.

Dr. Edebohl of New York and Dr. Sutton of Pittsburg were welcomed to the Convention and requested to participate in the discussions.

The Question of Medical Defence.—This was introduced by Dr. Russell Thomas of Lennoxville, Que., who had been delegated by the St. Francis District Association. He made a strong plea for the formation of a Medical Defence Union and thought that all were agreed of the necessity for such. He supported his contentions by citing two or three cases already well-known to medical practitioners in Canada and after showing that such Defence Unions were a success in England he concluded by outlining the plan of medical defence already in vogue and supported by the St. Francis District Medical Association which he was authorized and prepared to hand over to the Canadian Medical Association. The discussion of this important matter was deferred until later on in the session.

Address in Medicine.—"The Question of Medical Education."—Dr. J. H. Jones of Winnipeg delivered this address. In opening his remarks he referred to the unsolved problems of medical education, the importance of which were especially manifest in view of the establishment of a Dominion Medical Board. Uniform or equivalent curricula, he thought, would greatly facilitate paving the way for the accomplishment of this object. He thought that the great aim of the Canadian Medical Association should be to create a Dominion Medical Board upon such a sound and enduring basis that the qualifications could be registered in every province of the Dominion. They should not only be Canadian but Imperial, capable of registration in Great and Greater Britain. There should be no special education for the profession of medicine, and the defect in the pre-

liminary education of medical students should be corrected. The standard is not high enough. Many students came into the medical colleges, their minds totally unprepared, undisciplined, not competent to engage in the different studies of a profession with advantage. Dr. Jones would not eliminate Latin but would go a step farther and advocate, a more general knowledge of Greek, as Greek was *par excellence* the language of science. He quoted from two eminent authorities, who favor the retaining of "Classical Education" as training for professional studies. —Dr. Alexander Hill, a member of our own profession who is Master of Downing College, Cambridge and Professor Jebb of Berlin. He referred to medical matriculation examinations and deplored the lamentable defects in the English paper, the most neglected subject in our primary schools. From an experience of many years as an examiner at the University of Manitoba Dr. Jones has concluded that the teaching of English takes a very subordinate position in our schools. The defect was a universal one; and it was obvious that if English should become a prominent subject of medical matriculation examination every student ought to be able to express his thoughts coherently and intelligently. The didactic lecture came in for adverse criticism, and defects and useless wastes of time, which could be more profitably employed, were pointed out. Persistent work in the dissecting room under the guidance of an experienced demonstrator, who will describe, discuss, and constantly orally examine the student is a rational and effective method of teaching anatomy. Medical jurisprudence and sanitary science were not properly taught.

Dr. Jones supported the "case" method of teaching; and from personal experience he favors the English system of clinical clerkships and dresserships as the most feasible, practical and thorough for the development of medical teachings. He referred to the question of Dominion Registration and pointed out two serious objections to Dr. Roddick's Bill—first, the great number of the representatives of the Council, entailing expenses beyond, at least, our immediate resources; and second, the fact that one of the contracting parties to Dominion Registration may secede and the elaborate fabric, the work of many years, tumble to the ground. The able paper of Dr. Jones was received with much gratification by the Association.

Dr. R. B. Nevitt, Dean of the Woman's Medical College, Toronto, in moving a vote of thanks to Dr. Jones for his able paper, stated that he had placed his finger on the weak point of Medical Education. Dr. S. J. Tunstall of Vancouver, seconded the motion for the vote of thanks and also congratulated Dr. Jones for the excellent manner in which he presented his subject.

Dominion Registration.—Dr. T. G. Roddick of Montreal, who has so long and so ably advocated this much-to-be-desired measure, delivered a stirring address on the subject, ably reviewing the subject of Inter-Provincial Registration from the time of its inception to the introduction of his Bill at the last Session of the House of Commons. The special committee appointed on this subject had not yet reported, so the discussion was postponed until that committee had a chance to meet and report later on in the session. Dr. Roddick now seems to hold to the opinion that the suggestion of Dr. Britton of Toronto, representation by population, for Ontario at least, would be advisable.

Infectious Pneumonia.—Dr. W. S. Muir, Truro, Nova Scotia, read this paper. He reported four cases all of which had occurred between the 1st and the 13th of April of this year, in the same house and in the same family. The first occurred in a child of ten years, the disease terminating by crisis on the 6th day, the child making a good recovery. A sister, aged 14 years, contracted the disease; terminated by crisis on the 9th day, but followed two days after by left-sided pleuro-pneumonia. This proved fatal. The 3d occurred in a sister, 15 years of age, beginning with a pain on the left side and terminated on the

10th day by crisis and recovery. Number four developed pneumonia but recovery was quick, the patient being about in two weeks. There was no influenza in the town at the time. Dr. Muir spoke of the organism of pneumonia, its cultivation and its detection.

FIRST DAY—AFTERNOON SESSION.

President's Address.—As this was the first time that the Canadian Medical Association had met in Manitoba, Dr. Chown referred briefly to the future of that important province. Although less than 10% of the arable land was under cultivation, Manitoba's farmers would this year have a crop estimated at 85,000,000 bushels of grain. He then referred to the work performed in Winnipeg for the purpose of making that city a healthy one, and in spite of the level nature of the land, an excellent system of sewers had been introduced through all the streets; and efficient arrangements had been made for regular flushing of the sewers by means of tilting basins at the upper end of each main sewer. As Winnipeg has two rivers at her door, the problem of removing sewage was easily and safely solved. Dr. Chown then referred to the water supply and said that the people of Winnipeg enjoyed as pure water as could be found in the world. An examination of the city water would show, that there were in it only nine to thirty colonies of Bacteria. The water is taken from an artesian well seventeen feet in diameter and forty-eight feet deep, and although they have been pumping for months a supply of from two million to three million gallons per day, there is not the slightest evidence of any diminution of the amount flowing in. The well is supposed to tap an underground passage which runs from Lake Manitoba, and as this lake is 130 miles long the supply is inexhaustible. The underlying rock formation in that section of Manitoba is a magnesia limestone and, consequently, the water contains a large amount of the carbonate of lime and of magnesia and is too hard for satisfactory use in boilers and hot-water appliances. This is overcome by using Clarke's method of softening by precipitation of these carbonates through the action of lime water; and the softening plant is unique on this side of the Atlantic. Dr. Chown then referred to the question of tuberculosis and thought that Koch's tentative denial of the oneness of tuberculosis of man and tuberculosis of cattle still needs the proof of non-infectibility from cattle to man. He instanced cases of young farmers free from tuberculous taint, living in newly-built houses harboring no bacilli and separated by long distances from their neighbors, in whom tuberculosis constantly makes its appearance; and we have here an experiment on a wide scale, and if you can eliminate heredity, house infection and contagion from other causes, to what cause can you describe the origin of these outbreaks? Medical education, the plan of the Dominion Registration as introduced by Dr. Reddick, malaria fever, proprietary drugs, the progress in surgery and the future of bacteriology and hematology were subjects ably dealt with; and in concluding, Dr. Chown felt that a duty rests upon the medical profession to get at the true cause of all forms of disease and rescue the public from both the honest fanatic and the ignorant pretender by doing not only all what these claim, but doing more and doing it better.

Sir James Grant of Ottawa, moved a vote of thanks to the President and characterized the address as extremely interesting and instructive. Dr. J. L. Bray of Chatham seconded the motion.

Epidemic Cerebro-Spinal Meningitis.—Dr. James McKenty, Gretna, Manitoba, presented this paper, which gave an account of an epidemic occurring in North Dakota during the winter and spring of 1893. It occurred within an area extending fifty miles from east to west and twenty miles from north to south and was comparatively definitely limited. About 70 persons were seriously ill and almost as many others suffered from mild manifestations of the disease. Of the seventy cases twenty-five ended fatally, —a mortality of about 35%. In the practice of Dr. McKenty there occurred some thirty cases, a brief record of

twenty-two of these being kept. The average age was seventeen years; the youngest fifteen months; the oldest thirty-eight years. The duration of the illness extended from twelve hours to fifteen weeks. No post-mortem was made in any case. Dr. McKenty then described in detail the clinical aspects of several cases.

Splenic Anemia, with Case.—Dr. A. J. Macdonnell, Winnipeg, contributed this paper with the history of the case. This was an exceedingly rare disease. In 1898 the number of cases recorded did not exceed thirty, but since that time fifty additional cases have been reported. R. N., aged 27 years, born and lived all his life in Manitoba; family history good; environment good; has never had malaria; habits and mode of life good; positively never had syphilis. The present illness began in August 1899. Felt heavy on the right side with a feeling of fullness and weight. In January 1900 gave up work on account of muscular weakness. There was no vomiting. The patient consulted Dr. Macdonnell in March 1900, walking into his office with considerable difficulty. There was no enlargement of lymphatic glands. Enlargement of the stomach could never be percussed or palpated. Liver dullness was practically normal. There was no jaundice or pain in the liver region. The patient succumbed to the disease but no post-mortem was held. Another case, occurring in a patient aged seventeen, was reported. Dr. Bell made a blood-count in this case which at different times ranged 3,540,000, then 3,600,000, then 3,400,000, with 7,602 white-bloodcells. In this case all the other organs were normal. And there seemed to be no pre-disposing cause in this case. Dr. Macdonnell stated that only ten autopsies had been made on people dying from this disease. He referred to the conditions found post-mortem in these cases. The treatment was stated to be rest, diet, and vigorous doses of arsenic. The mortality is set down at 20%. As far as operation is concerned, physicians will not be satisfied until it is clear that the patient recovers from the operation as well as from the disease. If we are sure of our diagnosis, then surgical intervention is deemed advisable.

Physical Development.—Dr. J. N. Hutchinsen of Winnipeg, read a carefully prepared paper on Physical Development. The paper did not deal with anything new but called attention to and emphasized certain facts of considerable importance. He considered that children were sent to school at too early an age and as a result there was danger of brain over-work. He insisted upon the necessity of having healthy parents, and deplored the system of education which develops the mind at the expense of the body. He was an advocate of periodical lectures by duly qualified physicians to separate classes of boys and girls on the subject of sex; but the primary responsibility in this matter, he placed upon the parents. There would be real progress in the prevention of tuberculosis when people, the subject of the disease, recognize that they should not marry. The paper which was listened to with close attention closed with a reference to the problems of these unfortunates who are neither mentally nor physically qualified for the duties of life.

Report of Cases Treated with Super-Heated Dry Air.—Dr. W. H. Pepler of Toronto, introduced this subject in a paper which cited his experience and observations in the treatment of certain cases by this plan or process. He briefly described the apparatus and the method of treatment. It only takes twenty minutes to reach a heat of 300 degrees F. The average duration of the application of the heat is forty-five minutes. The physiological and therapeutical effects noticed were referred to, as dilatation of blood-vessels, etc. He administers the treatment one hour after meal time with due regard that there shall be as little as possible excitement and exertion. He has not seen any ill-effects from the treatment. He first gave notes of the case of a patient, a man aged thirty-five years, who had suffered for some time from varicose ulcer of the right leg, with considerable pain. This patient had a treatment of thirty-five minutes duration and was able to walk

home with very little discomfort. After three times, in ten days, the ulcer was very much reduced in size. The second case was a patient twenty-two years of age who had been troubled with rheumatism for two years past. A temperature of 320 degrees was employed with good satisfaction. Several other cases of rheumatism and eczema were reported. The treatment in each case proved highly satisfactory, patients never complaining of any discomfort and all expressing satisfaction with the treatment. Dr. Pepler subjects a considerable portion of the patient's body from a temperature of 280 to 320 degrees F. The results are often not apparent for some time after treatment.

Dr. McAdam of Battleford, asked Dr. Pepler if he had ever tried the treatment with high temperature, where he had any doubts of the condition of the heart.

Dr. MacDonald of Brandon, referred to a case which came under his observation in which there was heart trouble. Perspiration occurred freely but with no effect in a depressing way upon the circulation. Treatment in this case was continued for two weeks but he had never determined that there had been any effect upon the heart although there was a small heart-lesion at the time.

Dr. Pepler in reply; he could not speak personally as to any deleterious results from weak heart. Of course there were many cases reported where heart trouble was present. He personally had never noticed any heart or head symptoms in his case. He thought, with care, there would be no bad results.

Orthopedic Treatment of Deformities and Disabilities Resulting from Diseases of the Nervous System, with Special Reference to Tendon Transposition, by Dr. B. E. McKenzie of Toronto. He spoke of disabilities and deformities resulting from paralysis, some of which were commonly regarded as hopeless; but the conditions of a great majority of them were remediable and should receive a considerable amount of attention. He was at some pains to explain the respective motion of joints particularly the ankle joint and knee joint, especially calling attention to the normal conditions of equilibrium, and then showed how the muscles of some of the groups at times become paralyzed and the balance and equilibrium thereby destroyed. Mechanical treatment was often necessary and often efficacious as well; massage and electricity had their respective places but he made particular reference to the method of treatment that had been in vogue for twenty years and had been introduced on this continent by Dr. Parsh of Philadelphia. He went carefully into an explanation as to how muscles can be transferred from their usual point of action and then he gave an account of several cases in which he had successfully accomplished this. In his opinion amputation of a limb because of apparent disability should seldom or never be resorted to.

In answer to Dr. McAdam, Dr. McKenzie disapproved of jackets in treatment of curvature of the spine.

Dr. Clarence Starr, Toronto, stated the subject was of great interest to him as he was interested pretty largely upon the same lines of surgery. Dr. McKenzie has indicated a large number of cases of paralysis which can be wonderfully helped by operative procedures.

Dr. Starr thought that Dr. Bowlby of Boston, deserved a great deal of credit for the work he has performed in this connection.

Dr. H. B. Small of Ottawa, referred to a case Dr. McKenzie had operated on. In this case, previous to operation, the boy had great difficulty in arising from the sitting posture, and when walking he had to rest every few yards. After the operation he was very much improved and when Dr. Small last saw him about a week ago he could walk very easily, and never had to support himself. The improvement during the last four or five weeks was especially very marked.

SECOND DAY—MORNING SESSION.

Mild Smallpox.—Drs. G. A. Kennedy, McLeod, Alberta, presented this paper. It dealt with the recent outbreak

of the disease in the Northwest Territory, an outbreak which was wide-spread and which had existed for sometime before its true nature was recognized. Dr. Patterson, Quarantine Officer for the Dominion Government was satisfied that there had been 1,500 cases. A noteworthy fact was that the greatest number of cases occurred among the French Halfbreeds, who had never been vaccinated, and further, Indians on reserves had not suffered to any great extent as annual vaccination is the rule. Not one case was seen or heard of among Galicians, Doukhobors or Roumanians, which was due to the fact that compulsory vaccination was the rule in their youth and then they had been re-vaccinated on their recent passage across the Atlantic and at Halifax. Fifty per cent. of all cases were extremely mild in character; forty per cent. were cases of typical varioloid; ten per cent. were severe, almost confluent. The mortality was slight, only thirteen deaths occurring; the disease prevailed fully as much amongst adults as amongst children.

Dr. Muir, Truro, Nova Scotia, discussed the merits of the different vaccines on the market and the paper was further discussed by Dr. MacDonald of Brandon, Dr. Inglis of Winnipeg, Dr. D. H. Wilson of Vancouver, and Dr. Montzambert of Ottawa. The latter considered it he would unfortunate if the impression went abroad that any doubt existed in the minds of the members of The Canadian Medical Association as to the true nature of the disease which had been epidemic for some years. He considered the facts presented in Dr. Kennedy's paper relating to Doukhobors and Galicians were perhaps the most valuable portion of it. At the close of this discussion the following resolution was moved by Dr. R. S. Thornton, seconded by Dr. J. L. Bray and unanimously adopted:—"Resolved that in view of the general prevalence of smallpox throughout the continent this Association desires to urge upon the profession and the public generally the necessity of vaccination and re-vaccination."

Chronic Ulceration of the Stomach, Simulating Cancerous Disease. Relation of a case of Gastro-Enterostomy with Murphy Button, Recovery, by Dr. J. F. W. Ross, Toronto. This occurred in a woman twenty years of age, the condition of whose stomach had been bad for three years. She was a nurse in the Training School of a Hospital and her gastric condition grew gradually worse and worse. Dr. Ross was asked to see the patient by Dr. E. B. O'Reilly, Hamilton, in December, 1899. He found her emaciated with the opium habit already formed. In January, 1900, he again saw her with Dr. Griffin of Hamilton. At this time rectal alimentation was being persevered in with considerable benefit. In March, 1900, she was discharged from the Hospital and remained well for two weeks. As soon as food passed into the stomach great rigidity of the right rectus muscle was noted. When the patient came under Dr. Ross's attention she weighed 75 lbs. As malignant disease of the stomach is rare at this age of life, it was difficult to diagnose the tumor as such, and the symptoms pointed to the pyloric end of the stomach. It was not possible to say whether cancerous or not. The symptoms pointed to the presence of ulcer but the thickening easily made out led to the belief that malignant disease had been grafted on to the ulceration. Some dilatation also could be made out, but the rhythmic muscle waves so characteristic of pyloric obstruction could not be found; but a large growth was found at the pyloric end. The case was looked upon as hopeless and decision was arrived at not to remove the growth but to give temporary relief by gastro-enterostomy. This was done and the patient made an uninterrupted convalescence. Eleven months after the operation the patient weighed 140 lbs. and looked the picture of health. On examination of the abdomen no mass could be felt and the patient was not suffering from any gastric symptoms at all. Dr. Ross then went into the literature on the subject, quoting Ragge, Sydney Martia, Monihan, and Mayo Robson.

Dr. Laphorn Smith, Montreal, began the discussion stating that, the case was especially interesting to him but rather from the general practitioner's point of view. He believes that no case of cancer of the stomach ever begins as cancer of the stomach. First there is some sort of irritation of the mucous membrane. This irritation finally becomes a chronic ulcer and upon this the germ of cancer is engrafted, or whatever it is which is the essential constituent of the cancerous process.

Dr. Martin, Montreal, discussed the importance of the examination of the stomach contents in these cases.

Dr. Bruce, Toronto, stated that he had an experience with a case a year ago which corresponds closely to the one Dr. Ross has reported. His patient was thirty-eight years old.

Dr. Gilbert Gordon of Toronto thought we should look at these cases from the standpoint of the physician as well as from the standpoint of the surgeon.

Dr. Howitt of Guelph, stated that the second case of ulceration of the stomach upon which he operated was one of acute perforation.

Dr. Ross thanked them for the reception they had given his paper.

Some Forms of Hyperacidity and their Treatment.—Dr. C. F. Martin, of Montreal, presented notes of some interest judging from the results of systematic examination of the gastric contents. The unfortunate general employment of the term dyspepsia is responsible for the disregard of this condition. In the case of organic disease producing excessive secretion the diagnosis is often difficult. He gave the history of two cases in illustration, the second being in an individual forty-five years of age, who gave the usual history of having been ill for six months. There was no obstruction of the pylorus, but simple dilatation, and the diagnosis was hyperchlorhydria with simple dilatation of the stomach. He also referred to the medical treatment following gastro-enterostomy.

Dr. Maedonnell of Winnipeg discussed this paper.

Medical Defence.—The report of the Committee on Medical Defence was here presented by W. S. Muir, of Truro, Nova Scotia. It reported favorably on the formation of a Medical Union, and the organization thereof was immediately perfected. It will be known as the Medical Protective Association, will be incorporated, and will have for its object the protection of the character and interests of medical practitioners in Canada. It will further promote honorable practice, will aid in suppressing or prosecuting unauthorized practitioners and will seek to advise and defend or assist in defending members in cases where proceedings involving questions of professional principle or otherwise are brought against them and other like matters. Dr. R. W. Powell of Ottawa, was elected President; Dr. McKinnon of Ottawa, Secretary, and Dr. James Grant, Jr., of Ottawa, Treasurer.

Report of Committee on Dominion Registration.—It is proposed to secure an amendment to the B. M. A. Act, or, to take advantage of section 91 of that Act, and under it obtain legislation from the Dominion Parliament, by which the profession in Canada might form a Dominion Council and which could be supplemented by legislation by the various provinces recognizing any certificate of standing issued by the Dominion Council as entitling a holder to practice in such provinces. Dr. Muir approved Registration and spoke for the Province of Nova Scotia. Dr. Jones voiced the sentiments of the profession for Manitoba. Drs. A. A. McDonald, J. L. Bray, endorsed the scheme for Ontario. Dr. Russell Thomas spoke for Quebec. Dr. Christie said that New Brunswick was in favor of Dominion Registration. Dr. Lafferty said the Northwest Territories were favorable.

(To be Continued.)

British Congress On Tuberculosis

Continued from 396.

Remarks on Tuberculosis and its Treatment.—By Dr. Baradat, Cannes (French Riviera). In the case of tuberculosis, as in that of every infectious disease, two factors must be taken into consideration. The first of these is the infectious agent, the morphological and biological characters of which are so well known nowadays; the second is the soil which the agent has developed itself in, and whose characteristics are either acquired or hereditary. All rational medication must, to be complete and really efficacious, apply to these two factors, and take into account all the elements which arise in a given case. For, as Lendet says, tuberculosis presents, in its varied manifestations, special idiosyncrasies, differing absolutely from one individual to another. Under these conditions only can we hope to be victorious over this dread disease. As a matter of fact, a review of the new methods of treatment employed in dealing with tuberculosis reveals to us the fact that, although these methods are, without doubt, of real value, they are only efficacious against certain given systems, and possess no influence over the whole of the phenomena which are to be overcome; certainly, they have special indications, but they are insufficient, because their field of action is but a limited one. Amongst these indications, the comparative effects of which we shall examine later on, some are destined to improve and to strengthen the soil, others, on the contrary, are specific agents; they give rise to the diapedesis of the white globules, thus multiplying the means of defence with which the organism is provided in its struggle against the bacilli.

A thoroughly rational treatment should take both factors into account, that is to say, the medication employed should act in two ways, both as a dynamogenetic agent and as a specific. One is generally inclined to look upon each new method of treating as one that will immediately effect a radical cure of this terrible disease, without taking into account either the infectious agent and its toxins, or the soil on which these latter react.

We must oppose this tendency, and attempt a true, careful and impartial appreciation of the new medications.

Let us, for instance, take the case of an anemic patient: the Koch bacillus has invaded his organism, but still remains latent; if we leave this patient to himself his anemia will increase, his digestive activity will diminish, his strength dwindle away, and assimilation will be reduced to a minimum; there will be, as has truthfully been said, a failure of the whole organism.

What must be done to meet such a case?

Firstly, the organism must be strengthened, nutrition favored; it is here that a use is found for medications tending to produce these effects, such as arsenic in its more easily assimilable forms (cacodylates), tannin, iodine, cod liver oil, salt lotions, alcohol frictions, sea baths, a hygienic treatment.

By these means the bacilli will be kept under, their action neutralized, and as long as an equilibrium is maintained between the means of defence and the attack, the patient will live.

But a fatal time will come when the bacilli will gain the upper hand, and this under the influence of varied causes, to which an organism already infected will have to pay a large tribute, such as physiological troubles, grief, repeated bronchitis, influenza, measles, scarlatina, and, especially in the case of young subjects, intense physical and intellectual strain—too much bicycling, too much fast living, an excess of emulation and rivalry in examinations and competitions.

So that this treatment of the soil, if we may be allowed this expression, which seemed at first so efficacious, had but an ephemeral effect; enough had not been accomplished, the disease should have been attacked in its very essence, the bacilli and their toxins destroyed.

It is the same with all medications in the case of tuberculosis, and I should willingly call them partial medications.

Let us consider those that address themselves to the soil, the constitution of the subject.

Firstly, we hold that a hygienic treatment should be the basis, the indispensable foundation-stone of every medication; without it, they will all fail.

As Professor Letulle so picturesquely puts it, the patient must be "centrifuged," he must be taken away from large towns, from the centres where diseased persons are collected; he must be given the pure, fresh, invigorating air of the seaside or of the mountains; he must have in profusion sunlight, an agent as salutary to man as it is destructive to microbes.

In our opinion, this hygienic treatment will best be realized by means of *free sanatoria*, Landouzy's home sanatoria, such as we find them scattered, in the shape of villas, along our sun-bathed Mediterranean shores. There all the required conditions, not only hygienic, but moral and inspiring as well, can be fulfilled.

In private sanatoria for the rich, the culinary arrangements for such a large number of people are necessarily unsatisfactory, the cooking is less carefully attended to, the dishes less carefully prepared, and less adapted to the question of individual wants, to stomachs often fatigued and upset. As a matter of fact, the question of food is of vital importance in the treatment of a disease in which superalimentation plays such an important part.

The private sanatorium should be reserved for the impulsive, for those who are incapable of energy and self-direction.

Besides, how many of these sanatoria are carelessly conducted! How many paying sanatoria are under the control of commercial managers, who allow alcohol in all its forms to be freely distributed! who close their eyes to promiscuities which are dangerous, often immoral and always harmful to patients who must carefully husband their strength?

On the contrary, we willingly acknowledge the usefulness of the sanatorium destined to the poor. In their case, hygienic discipline will always be maintained, for there will be no reason for unbending the perspective of rapid gains and big dividends; on the other hand, the poor will always find at a sanatorium better feeding than at home.

As for medical treatment, much has been said of cacodylate of sodium.

We shall not attempt a complete study of this substance. The most important thing for us is to be thoroughly acquainted with its real value. Its action and its efficiency must be measured by the light of the experience of numerous observers, and of our own. Its promoters were wrong, in our opinion, to call cacodylate of sodium a specific agent against tuberculosis. As against the numerous favorable observations, and which we do not doubt in the least, of Messrs. A. Gauthier, Renaut, Letulle and others, we have to set off many others, equally unimpeachable, and where the results on tuberculosis have been nil.

In the course of our practice, we currently employ cacodylate of sodium; its effects have proved excellent in cases of anemia, of ganglionic and lymphatic persons, of chlorosis. In such cases, we have observed a regular revival of the physiological functions, an increase of appetite, a resorption of ganglia. On the contrary, we have obtained less favorable results in cases of ulcerous and cavitory tuberculosis.

Hurlureau, in a recent and thoroughly complete study on cacodylate, has come to the same conclusion. "As for tuberculosis," he says, "I regret to have to say that, contrary to the opinion of Professor Gauthier, it is in this disease that cacodylate has given me the least favorable results. Out of twenty-nine cases of tuberculosis, I have only once obtained a really favorable effect, and that was but temporary."

Cacodylate will be specially useful for the predisposed, for those incipient cases which were so difficult to diagnose, and which we have now learned to recognize.*

As for the vanadates, they have not fulfilled the expectations formed of them; but this is partly due to the difficulty experienced in obtaining thoroughly determined products.

The same must be said of certain artificial serums, which must be classed among the soil strengtheners, and are wanting in bactericidal powers, or rather in the power of exciting diapedesis and phagocytosis.

We now come to the raw meat treatment.

The experimental researches of Richet and Héricourt have proved that raw meat juice acts, not as a strengthening agent, but as an antitoxin. This antitoxin would neutralize the effects of the tuberculous toxin.

This juice is the muscular plasma, obtained either by the press or by congelation followed by rapid thawing of the muscular tissue.

The following is the method I have adopted at Cannes in the case of patients whom I submit to this treatment: the daily quantity of mashed meat is 800 grs. (28 ozs. about); the patient takes as much as he can, the rest of the meat is pressed, in order that the juice may be extracted.

The plasma must be taken immediately after having been prepared, otherwise one risks swallowing a putrefied and toxic substance.

Although this method has given me excellent results, I consider it difficult to put into every day practice.

It possesses many inconveniences; for one thing, it is not within everybody's reach; it is costly in preparation, and requires 800 to 1500 grs. of meat daily; it is supported with difficulty by many patients; it requires constant supervision, for this meat juice soon putrefies and becomes toxic. Injected under the skin of an animal, it causes death in a few minutes.

Experiments with this anti-tuberculous plasma have been made in the laboratory of Messrs. Richet and Héricourt. These attempts at hypodermic injection of an immunizing and even curative liquid led us to read once more the already old but very incomplete works on the bactericidal or antitoxic properties of the blood of animals that are refractory, or seemingly refractory, to tuberculosis.

The medical literature of 1890 to 1895 show us how this question has been strenuously discussed and deeply criticized.

However, from these works we glean the following fact: that the blood of certain animals confers on other animals immunity from tuberculosis, and may even cure this disease. "As far back as 1888," says Professor Bouchard, in writing to Mr. Bertin, one of the promoters of anti-tuberculosis sero-therapy, "I expressed the idea that vaccines were destined to play a part, not only in the prophylaxis, but also in the treatment of this disease."

For my own part, I have no hesitation in attaching myself to the method of anti-tuberculous sero-therapy introduced, at about the same time, in 1889, by Richet and Héricourt, and by Bertin and Picq, for I think that therein lies the solution, so long sought, of the problem of the cure of tuberculosis.

Naturally, with this medication just as with any other, we must not wait for the patient to be emaciated, to present digestive troubles and cachexia before treating him.

For, we insist on this point, tuberculosis is not consumption. A consumptive or phthisical person is one in whose case the Koch bacillus, after having terminated its progressive career, has slowly brought on the suppurative destruction of the cells attacked, and in this mass of destroyed matter, you will find all the processes provoked by the staphylo-, the strepto-, and the pneumococcus, working together with the Koch bacillus.

In this case, you have phthisis, consumption, the hectic fever which brings on a fatal issue; imagine that, by some means, you could at this period destroy the bacilli of tuberculosis, your patient would still succumb to the strepto-, the staphylo-, and the pneumococcus.

*For instance, Landouzy, Grancher, Sanchez have revealed to us the delicate stethoscopic signs of the period of germination; Bard and Paisans have showed us the importance of the cardiac rhythm, of tachycardia; Roussel and Bolx that of the scapulo-thoracic amyotopia; Bouchard, Beclere, Kelsch, Maragliano have taught us the radioscopic signs of incipient tuberculosis; Arloing Mongour, Courmont have established on a sure basis the early diagnosis of tuberculosis by sero-diagnosis by agglutination; Albert Robin and Binet give us the same certitude by the analysis of the respiratory chemism; Sirot and Pinc by the observations of the effects produced by injections of artificial serum; Gaube (of Gers) by the study of the demineralisation of the tissues.

As a matter of fact, says Landouzy, it is this idea of helping those who are in the incipient stage, at a time when the germs of secondary infection have not yet attacked them, that has led medical men to make use of "the immunizing agents that are anti-toxic or bactericidal owing to their strengthening action on phagocytosis."

This science of sero-therapy, which we owe entirely to the French school, has been perfected by Pasteur's most renowned disciples, by Drs. Ducheaux, Itoux, Granicher, No-card, Metschnikoff, Verslin, Calmette, Leroux, Charrin, Marmorek, Dolnet, and many others, among whom we must mention Bertin and Picq, who were, together with Hiebet and Héricourt, the promoters of modern sero-therapy.

The use of natural serum has given me unexpected results in serious cases of tuberculosis, and I have always been surprised to find that this method of treatment is not better known; natural serum seems to me to fulfill all the required conditions, for it is both dynamic and bactericidal.

As we know, in the case of tuberculosis, the bacillus acts as a destructive force, but its action is strengthened by that of other destructive forces due to the soil. In one case it will be anemia, in another heredity, in another influenza, or intellectual or physical strain.

So, with these generalities, what are the characters required of a therapeutic agent against tuberculosis? We admit the stimulating and regenerative properties of the general tonics, cacodylates, phosphates, cod liver oil, etc.; we will even allow the antitoxic property of meat juice, but has anyone the right to say that each of these agents fulfills the two conditions necessary to the cure of tuberculosis? Certainly not, for they are either simply stimulating and strengthening, or simply antitoxic. Bertin and Picq's serum (goat's serum) seems to me, on the other hand, to be at the same time tonic, antitoxic, and bactericidal; it is the one we make use of.

As a matter of fact, daily experience tends to prove that every serum is dynamogenetic, and therefore a general strengthening agent.

This is proved daily by the use of artificial serum in the case of serious hemorrhage, of anemia subsequent to chronic diseases, of traumatic shock consecutive to operations. In taking into account, however, the comparative value of the two serums, natural and artificial, we find that a very small quantity of the former produces an intense therapeutic effect, whilst the same effect can only be obtained by employing a double or even triple dose of artificial serum. There is here a *quid divinum*, due evidently to the intimate composition of natural serum. No one nowadays denies the dynamogenetic action of serum—it is a recognized fact.

All we have to do is to repeat this action as often as required in order to maintain to a remarkable degree the resistance and vitality of the patient.

Whilst awaiting experiments destined to throw light on the still obscure question of the mode of action of serums, we give preference to the theory propounded by Metschnikoff, who looks upon them, not as antitoxic, but as stimulating agents of phagocytosis, in other words, as *stimulus*, provokers of organic resistance.

Therefore, as we admit that the microbial destruction and the arrest of infection are due to phagocytosis, the aim of our therapy must be to increase the activity of the phagocytes, in order that they may the more easily accomplish their mission. Moreover, the happy results that we have obtained this winter by means of sero-therapy lead us to believe that this is the real and only effective method of realizing the cure of tuberculosis, especially in its early stages, now that the means of diagnosis which we possess permit us to discover the very earliest symptoms of incipient tuberculosis.

This treatment is absolutely innocuous and easily applied; one hypodermic injection of two cubic centimetres every other day. In some cases, however, in the case of nerve patients especially, I have observed after each injection an exaggeration of cellular activity, showing itself in the shape of fever, erythema, and dyspnea; in such cases I administer the serum internally. But, in order to obtain the same tonic and stimulating effects, I have to increase the dose, and administer ten cubic centimetres instead of two, as in the case of hypodermic injections.

These results agree with those obtained by Grasset,

who concludes by saying that the administration of serum internally is the method of choice, because it is free from danger and gives rise to no accidents. Nevertheless, even with Bertin's serum, we are of opinion that the cacodylate medication should be employed as a precious adjuvant in most cases on the same level as tannin, iodine, and cod liver oil.

Devitalized Air Toxemia a Prime Cause of Tuberculosis. By Dr. Charles Denison, Denver, Colorado. Under the this head it is intended to discuss the *degenerative effects of deficient ventilation*, and to show how, through the devitalization of the air, by its loss of vitality, due probably to a change in its normal electrical state, a dyscrasia (in persons breathing it) is created, which gradually drifts into degeneration of tissue, the so-called "soil" of tuberculosis. The Richardson experiment is discussed, and the need is emphasized of further experimentation on this line in order to throw more light upon this important matter. The prevailing idea among medical men that the tuberculosis germ is the only cause, to the exclusion of as important predisposing causes, is criticized. The question of "soil" is now even more important than that of "seed," in order to successfully combat this dyscrasic disease. Man, under our present civilization, is very generally tainted with a dyscrasia which goes back to this devitalized air toxemia for its cause. The fault is the disproportion of breathing-space and sun influence to the needs of man in sleeping, living, and working rooms. The *deficient ventilation curve*, upon which the most civilized peoples are living, will, by illustration, be contrasted with the *normal life curve*, which should represent the longer and uncontaminated lives of a people living under natural conditions. *Out-door life* is thus suggested as the *key note* to this congress. The need of education along these lines will be emphasized, and plans for legislative control, through yet to be enacted laws, will be suggested.

The Role of the Nasal Fossae in the Prophylaxis and Treatment of Pulmonary Tuberculosis. By Dr. Maurice Mignon, Nice. When we consider the question of the prophylaxis of tuberculosis, we must recognize the fact that contagion takes place chiefly through the air. Air is the vehicle by which the microbes invade the organism far more frequently than foods, which can be sterilized by cooking. When the air is still infective, in spite of the use of spittoons, in spite of the practice of disinfection, in spite of every precaution intended to prevent the spread of the disease, the nasal fossae are still capable of arresting the danger that threatens us. The microbes that enter with the air are, in a large measure, arrested by the cilia of the nasal vestibule and by the very extensive and very irregular surface of the mucous membrane. One may thus recognize the bactericidal function of the nasal mucus, although it has been questioned by some authors. Clinical experience teaches, indeed, that the nasal fossae are much more resistant to tuberculosis than the rest of the respiratory tract, and even than the bucco-pharyngeal cavity. Insufficient nasal permeability (nasal obstruction from malformations or septal ridges, from hypertrophic or congestive rhinitis, from cysts, vegetations, adenoids, etc.), should therefore be reckoned among the dangers of tuberculous infection. From the point of view of treatment the state of the nasal fossae is of equal importance. As the nose allows more air to enter than the mouth, nasal insufficiency results in deficient oxidation of the blood, and everyone knows how necessary oxygen is to the tuberculous. Entering by the mouth the air brings with it harmful microbes, which, accompanied by dust, favor the malady. Moreover, this air, insufficient and injurious, is unmodified, either in temperature or in pressure; it provokes bucco-pharyngeal, laryngeal and tracheo-bronchial inflammations which impede the action of treatment. It is therefore absolutely necessary that we should be satisfied that patients presenting themselves for examination (especially those disposed to tuberculosis, and those who are themselves tuberculous) are not suffering from any cause of nasal insufficiency. If any defect is present it should be remedied, and we should enjoin the patients to breathe solely by the nose as soon as they are able, for in this habit often plays a part. Instruction on the latter point should be included in the general advice which one makes a point of disseminating amongst all classes of the population.

Original Articles.

THE ETIOLOGY AND EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.*

By D. GILBERT GORDON, B. A., M. D.,

of Toronto, Canada.

Professor of Sanitary Science and Assistant Professor of Clinical Medicine in Trinity University, Toronto. Physician out-door Department, Toronto General Hospital.

It is not a thing to be wondered at that this subject of tuberculosis should be receiving, as it always has done, so much attention from the members of our great profession all the world over. For does not this dread scourge claim as its toll, year by year, about one-fifth of those who go down to death, more than all the other infectious diseases put together. Not satisfied with this, it insists, too, that its victims be taken in great part, at that time, when it is most sweet to live and most hard to die. The most important causes of this disease as found in the lungs and its early detection I desire to treat of in this paper. I feel rather relieved that at the present juncture I need have nothing to say as to the part played by tubercle in meat or milk, for we must all be agreed that as far as pulmonary tuberculosis, at least, is concerned the tubercle bacillus received into the system by the ingesta must play a very unimportant part in its etiology. The direct inheritance of the disease must also be very rare indeed. The only direct cause worth while troubling ourselves about is the inhalation of dried sputum beladen with this tubercle bacillus. This is practically the only source of pulmonary tuberculosis.

But there are other causes which we speak of as predisposing causes all important to us, for by removing, as we are able, these causes we will so cripple our enemy, so remove him from his base of supplies that he will be forced to quit the open field and content himself with the meanest kind of guerilla warfare. What are these causes?

1. Insufficient ventilation and sunlight.
2. Insanitary condition of dwellings, work shops and factories.
3. Density of population.
4. Occupation.
5. Alcoholism.
6. Previous attacks of certain diseases.

Insufficient Ventilation and Sunlight.

With regard to these bacilli it is certainly true that they "Love darkness rather than light," I suppose. "Because their deeds are evil." However, we are certain if we could drive them out of their favorite haunts of darkness and dirt, soon their virulency and aggressiveness would be much diminished.

Insanitary Conditions.

We all know that this is eminently a dirt disease. It should therefore, be placed among the commonly known seven zymotic diseases. Dr. Henry J. Bowditch, as long as fifty years ago, pointed out the close relationship existing between moisture and consumption, and says that "residence near a damp

soil, whether due to inherent dampness or that from percolation from adjacent soils is one of the chief causes of consumption in Massachusetts, and probably elsewhere." He states also, that consumption can be checked in its career or perhaps prevented by observing this law. These statements were made thirty ears before the discovery of the bacillus by the great and noble Koch, and although it is not now believed that the bacilli can breed in the soil and thus impregnate soil air and be drawn into the respiratory air and thus infect man, yet the truth of the statement has never been gainsayed that dampness and dirt are important predisposing causes to pulmonary tuberculosis. In this connection allow me to quote the words of Professor P. Brouardel, of Paris, taken from his paper read at the great conference on tuberculosis held in London a few weeks ago. He says: "Before the scientists I have just mentioned had actually made known their discoveries you English people had already begun the struggle. Convinced by observation that tuberculosis thrived in dark and damp dwellings, in 1836, nearly seventy years ago, you passed a law providing for the construction of healthy houses. And since that date your zeal has not abated. You have with admirable perseverance passed more than ten acts of Parliament; you have rendered salubrious the dwellings of the poor; the workshop, the town and the whole kingdom. This effort has been described by the name of the Queen, who presided over its direction, "The Victorian Era." No greater homage could be paid to Her Most Gracious Majesty, and in the name of all my countrymen I unite with my English colleagues in adopting this characteristic name for the crusade that was undertaken and for the success obtained. You have diminished mortality in England from tuberculosis by forty per cent. Yours is the honor. It will be ours to follow in your steps."

Density of Population.

It is a matter of common observation that this disease is not only more prevalent but more rapidly fatal in those communities where people are huddled together necessarily in conditions of poverty. I copy here a table by Dr. J. B. Russell to the Philosophical Society of Glasgow taken from the Hygiene of Transmissible Diseases by Abbott, which shows the truth of the above as found in Glasgow.

Table showing death rate per 100,000 from certain houses:

	1 and 2 roomed houses	3 and 4 rooms	5 rooms and upward
Zymotic disease,	478	246	114
Acute diseases of lungs including consumption	985	689	328
Nervous diseases and diseases of nutrition	480	235	91

It is gratifying to see that efforts are everywhere being made to eradicate this plague. In Canada—it hurts me to say it—we are woefully behind in this respect. The attention of our Governments and our wealthy men should be persistently directed to this great need. Although the public doubtless is grateful for millions spent on public libraries in their interests, yet it does seem to me that some millions spent in providing means to be used to prevent the spread of this awful plague by which undoubtedly

* Read at the meeting of the Canadian Medical Association at Winnipeg, Aug. 1901, and published synchronously with its appearance in the *Canada Lancet*.

hundreds of lives would be annually saved from infection, would yield a more satisfactory interest on investment than that spent to endow public libraries, or even that spent for payment of fees of a nation's prospective university students.

Occupation.

No doubt occupation bears an important relationship to the causation of pulmonary tuberculosis, but there is no doubt but that the occupation itself is less a causative factor than the condition of the surroundings under which the occupation is carried on.

With regard to alcohol as an etiological factor in tuberculosis I quote again from Professor Brouardel in the *British Medical Journal*. He says: "Unhealthy dwellings cause other disasters. Dark and crowded as they are, cleanliness is difficult if not impossible to preserve. They are not pleasant to pass the time in, and the workman stays in his home as little as possible. He eats there and sleeps there, but the rest of his time is spent in the public house. Sir John Simon was right in saying 'the wretched lodging is the purveyor of the public house.'" And we can add to it that the public house is the purveyor of tuberculosis. In fact, alcoholism is the most potent factor in propagating tuberculosis. The strongest man, who has once taken to drink, is powerless against it.

Previous Attacks of Disease.

The dread disease greatly strengthens its position in its warfare against mankind by the favorable alliances it has succeeded in making, alliances with such diseases as la grippe, pneumonia, pleurisy or bronchitis. An attack by one of these affections does frequently act as an etiological factor in tuberculosis. Or to continue the metaphor that he is unable to resist the onslaught of the relentless tubercle.

The Early Diagnosis of Pulmonary Tuberculosis.

Writers on this subject are in the habit of dividing this disease into stages. We therefore see it divided into a first, second and third stage. We speak also of a pre-tubercular stage, the stage before there is any expectation and generally before the bacilli can be found in the sputum. It is very evident that these stages cannot be well defined. The degree of advancement in each stage differing according to the examiner. This, I have no doubt, accounts largely for the discrepancies found in statistics as to cures in the different stages. Over and over again I am forced to make up my mind as to this question. Has this patient, who is trusting himself to me, the tubercle bacillus in his lung or has he not? If he have, and I being at the time a little hurried or perhaps a little wearied, tell him after a very cursory examination that he has a little cold, but that it is just in his tubes, and that his lungs are all right, then I have done my patient a great wrong. He goes away relieved, but in a few months, not being well, consults some other man who tells him that he has consumption. We may not be able to make a diagnosis on our first examination, but before we allow the patient out of our hands we should do our best to ascertain his condition. The means at our disposal for this purpose are:

First.—The ascertaining of the presence of certain symptoms indicating the tuberculous condition.

Second.—The patient and careful study of the thorax for those symptoms pointing to the same.

Third.—The examination by the Röntgen ray.

Fourth.—The use of the tuberculin test.

Fifth.—The microscopic examination of the sputum.

I will first consider the value of a careful study of the existing symptoms, not because I consider them so important as the physical signs in aiding us to make our diagnosis, but because on account of their presence the patient is, for the most part, first led to seek our advice.

In discussing this question I do not purpose to take into consideration those symptoms or signs so evident during the later stages of the disease, but only those which I have found to be of use in making a diagnosis before, if possible, the tubercle bacillus can be found in the sputum. Our patient is before us. The question of inherited tendencies or the most important question of exposure to infection should be considered.

The presence of cough is in my experience the most common danger signal. Generally a short, hacking cough noticed especially if the patient is about to speak or after full inspiration. It may be the common "clearing of the throat." It may be bronchial. A cough persistent with morning expectoration, bronchial in character, I have found frequently to become tubercular in origin and I believe frequently is. The cough may simply be due to a bad cold; it may follow an attack of pneumonia or gripe. In these cases we must satisfy ourselves that the condition is not tubercular in origin or that it has not become so. There are, of course, other causes for cough, but a persistent cough should make us suspicious.

Hemoptysis.

As we all know, the spitting of bright blood, while not a very common symptom in incipient tuberculosis, is a very certain one and often a very early one.

Giving a case of bloodspitting, whether in mouthfuls of bright blood or as tinged sputum in which we can exclude laryngeal disease and chronic heart disease by examination of the larynx and heart, and pneumonia and carcinoma by the nature of the expectoration, and one hundred to one the case is tubercular.

Temperature.

A slight elevation of temperature, an elevation of 1 or 1½ degrees occurring between three o'clock and four o'clock in the afternoon, and this continuing for some time, is a symptom that should claim our attention. Should the temperature go up a little higher after a slight exercise and perhaps disappear with a two weeks' rest in bed, we are still more convinced that it is due to tubercular influence. An increased pulse rate we expect with this rise in temperature, which increase persists frequently when the temperature is normal.

Pain.

Sometimes the first symptom complained of is a pain in the upper part or less frequently in the side of the chest. Probably pleuritic in character. The absence of pain, in so many of these cases, is one of nature's delinquencies, and like many another failure in duty results in dire consequences. Gastric

disturbances taken with other symptoms are important.

Physical Signs.

Our attention having been directed by the symptoms to the threatened condition of our patient; we proceed to examine his chest. He, or she, must be stripped to the waist, placed in a good light (I prefer to have him standing before me where he can be moved about at will). I think it important that a regular order should always be adhered to in making this examination. Repetition tends to perfection. If there is one thing more than another which I should like to emphasize it is this, the importance of taking plenty of time with this examination. I have been surprised when going over a chest again and again with a class of students, to find how signs gradually become clearer, and when once detected (like bacilli under a microscope) they were plainly observed. The order generally observed is, I think, the best, namely, examination by inspection, palpation, percussion, and auscultation.

Inspection.

Examination by this method does not give us much information at this very early stage. When, however, the disease has progressed somewhat the information gained in this way is most valuable. Yet inspection tells us something of interest to us even now. The long, narrow chest, oblique ribs, prominent clavicles, acute epigastric angle-winged scapulae, will indicate a pre-disposition to tuberculosis. Should the patient have suffered much from pain there may be noticed over the affected part a diminished expansion.

Palpation.

By this method we may perhaps distinguish the nature of the pain, if there has existed any. Should there be any considerable infiltration, and that near the surface of the lung, we may be able to notice an increased tactile fremitus.

Percussion.

With great care and light percussion a tuberculous nodule or even a small infiltrated mass may cause a slightly dull and high pitched percussion note over the affected part, but what I have found more useful at this stage is a more resonant and prolonged note in the neighborhood of the dulness.

Auscultation.

It is, I think, to this means of examination that we will have to trust for our most reliable early diagnostic signs. And the first sign I would notice is that of impaired breathing, a most markedly enfeebled inspiratory sound over the affected part, at the same time there may be, if not, there will be later an increased expiratory sound, and later still the regular harsh bronchial breathing. Here also the increased voice sound is a most valuable sign. Bronchophony I have often found very early. Whispering pectoriloquy likewise. It is well to examine at first the patient breathing naturally, afterwards by more forced breathing. There is one other sign which I should like to mention; though rare, it is when present, very striking, and often early, that is, a markedly interrupted breathing, cog-wheeled respiration. Every part of the thoracic wall where the lung can be reached should be carefully gone over,

and here I should like to emphasize the importance of examining particularly the inter and supra scapular regions as well as the clavicular regions for evidences of disease. While it is not possible to have a standard of normality for chest sounds owing to the different relationship in different persons, yet, taking into consideration the thickness of the wall in each case we should have some idea of what would be normal in that particular case. Then we can use to great advantage the rapid comparison of one part with a corresponding one on the opposite side of the thorax. If the phonendoscope is being used for the purpose of testing the voice sounds, on account of the sensitiveness of this instrument we will be led into error should we forget that on account of the greater number and greater size of the bronchi on the right side the voice sounds are normally increased.

The Roentgen Ray.

This as a means of diagnosis is certainly valuable, and as a confirmatory sign specially so, and in many cases it will in skilled hands discover the enemy. Dr. Francis H. Williams, of Boston, has done most useful work in this connection. In the *Medical Record*, May 13th, 1899, he states that in five cases he discovered by the X-Ray changes in the lung before they could be detected by physical signs. The *Philadelphia Medical Journal* reports six cases examined by Dr. Williams, in which he claims that the diagnosis was made more certain by the use of the X-Ray. It is a method quite free from risk and should be used where practicable. My own experience has been limited in this method of examination, but where I have used it, it has not disappointed me. This month, by the kind assistance of Dr. John McMaster, at the Toronto General Hospital, I examined five patients by the X-Ray. In two of these, where there was but little doubt, the haziness over the parts affected and the limited excursion of the diaphragm were marked.

In one case where there was some doubt the diagnosis was not made plainer.

In the other two it was most helpful as an aid to diagnosis.

The last three cases were in the pre-tubercular stage.

The Tuberculin Test.

This test for diagnostic purposes alone is when used in suitable cases the most certain of all tests, with the exception of the discovery of the germ by the microscope. Advanced cases appear to be non-reactive. The reaction is imperfect also where sarcoma, carcinoma or syphilis exists. And, moreover, it has been pointed out by Trudeau and others that a reaction occurs sometimes in the apparently healthy. In how many of these there may have been latent tuberculosis it would be impossible to say. But what seems to me to exclude from general use this valuable diagnostic test is this, that still many able men aver that the use of this test is dangerous to the patient; that it often kindles the smouldering embers of a dangerous fire.

Microscopical Examination.

The discovery of the tubercle bacillus by the microscope is the one absolutely certain sign that we possess of the existence of pulmonary tuberculosis.

and where any expectoration can be secured, if only a little in the morning, this should be given to a skilled microscopist for examination. But, I would feel inclined to disagree with Professor Llewellyn P. Barbour when he stated in a most excellent paper published in the *Medical Record* of June, 1896, "That if after several attempts by one skilled in the procedure no bacilli are found phthisis may be excluded." This statement was made in 1896. I think all agree now that the disease can be diagnosed in most cases before the bacilli can be found. I would also hope to believe, and do believe, that the statement made by Dr. Barbour in the same paper that not more than one in twenty first-stage cases are recognized, is not true now, and that similar statements made by Dr. Ambler in the *New York Medical Journal* of 1898 are also now not true. We must not trust to one symptom alone. Neither must we be satisfied by one examination alone, but we must spare neither trouble, time nor expense to prevent our patient the loss of months which will in all likelihood mean to him the loss of his life. The study of symptoms and signs must go together, and while I believe that the stethoscope or some allied instrument is the most useful instrument we have for this purpose, yet we must not forget that there is truth in the statement which has been so well put in *American Medicine*, August 3d, of this year: "The absence of audible evidence of internal lesions is a remarkable fact in many cases of even advanced tuberculosis and physical signs may come and go in a way that baffles explanation and discourages the investigator."

THE EMPLOYMENT OF THE RECUPERATIVE POWER OF THE HEART AS AN ESTIMATE OF ITS FUNCTIONAL ABILITY.

By DR. MARTIN MENDELSON.

University Professor at Berlin

Translated, with permission of the Author, by Max R. Dinkelspiel.

Among the many transformations that take place in the course of development of modern medicine, the most remarkable of all is, that diagnosis more and more directs itself toward ascertaining, not, as has been the custom, the altered condition of an organ, but rather its altered functional power. This is done with a good reason. For the highest mission of clinical medicine is always to preserve or increase the functional power of individual organs or groups of organs, for it cannot, or very slightly, influence tissue changes as has long been its unfulfilled hope. By this very fact surgical therapy and internal therapy are most vividly differentiated, in that one directs its power toward the bodily material of the organism, and influences it by depriving the body of dispensable substances, while internal therapy operates only functionally with stimuli, and with powers invested in various vehicles, that only affect the function and not the substratum of the organism.

Clinical medicine must also adapt its therapeutic mission to its diagnostic one and particularly so in

the case of the heart. With the most accurate demonstration of anatomical changes we still have no knowledge whatever as to how far these changes influence the power of the heart; for it is only the latter which is of importance in maintaining circulatory power, and not the actual condition of the heart itself. The physician to whom a patient with heart disease presents himself, is confronted with the task to so regulate the demands that are made from the heart of the patient in the future, that the cardiac power which is present may be able to sufficiently maintain the circulation; and he will only be able to fulfill this task when he is enabled in every case and at every time to recognize and estimate the functional power of the organ. Clinically many attempts have been made to establish such a functional diagnosis. Recently, as is well known, the patients have been instructed to perform many exertions during the examination, such as climbing stairs, bending the knees, running backward and forward, and many others, in order that it may be seen how, with these exercises, the cardiac function is affected, keeping in view what has been learned by experience, that the weaker the heart the more actively does it react to such stimuli. But an exact estimation can never be obtained. A further experiment was then made by ascertaining the degree of cardiac power which resulted from an accurate amount of imposed work causing acceleration of the heart's action; neither Christ (1) nor Staehelin (2) could find any generally definite relation between the amount of work performed and the cardiac acceleration. Kraus (3) then employed the amount of fatigue caused by accurate doses of work as an estimate of the individual constitution; those experimented upon performed a maximum amount of work up to the point of exhaustion; and the "economic gain" was determined according to the degree of work performed, thus leading up to the inference as to the total constitutional power of the individual and then that of his heart. But in this case there was always selected, as an indicator, the exhaustion of the whole organism, and not the beginning of cardiac fatigue, which is by no means a feasible estimate for determining the power of the heart; for a diagnostic method, which demands complete exhaustion from the patient, can only be available for physiologists, and not for physicians; and, furthermore, it is very difficult, if not impossible, in cases of progressive exertion, to accurately determine the moment at which the "fatigue" occurs. Especially true is this of the heart, for if the conception of the term "fatigue" is stretched in that we assume in other organs it occurs until these refuse to further perform their functions, it certainly is not applicable in the case of the heart; it is, therefore, purely arbitrariness to claim that a certain degree of cardiac acceleration, dyspnea or disturbing symptoms, should be considered as indicators for complete cardiac fatigue. Fatigue is not

available for a functional diagnosis of the heart, and is a dangerous procedure for the patient.

I would like to briefly report the results of experiments which I have performed, and established facts resulting therefrom, and in which an entirely new experimental phase was employed as an estimate of functional diagnosis of the heart, a procedure which will be found to be suitably available, not only in the case of the heart, but for entire functional diagnosis. This is, namely, "recuperation."

As the most important point of these investigations I desire to emphasize the statement that every cell, every organ, every organism, is the better able to thoroughly exert its functional power, the more it is enabled to replace the material which has been consumed during its function. Of course, upon this depend congenital differences of constitution, which cause variations in functional capacity, according to whether the individuals be vigorous or weak; and in addition, there must also be considered the difference that exists in the acquired demands of youthful and aged organs. It is easily comprehended that every cell in a living organism stores up energy which it again gives up under the influence of stimuli; but it will always remain an enigma why the energy which is stored up by the muscle cell, when it becomes unloaded and transformed into living power should give rise to mechanical service, why the energy garnered in the glandular cell should be endowed with specific mechanical power, why the energy taken up by the ganglion cell should result in a sensory or physical expression, and why all the various cells of the organism around which the same stream of nutritive substance flows, should exert a selective affinity for the particular material, needed to replace that which has been consumed. Thus every active cell in the organism represents to a certain degree a transformer, which collects within itself energies which, according to the peculiarities of each particular cell, are again transformed and given up; the qualitative and specific transformation occurring in these processes must be considered by us as due to a congenital peculiarity of the economy. The quantitative phenomenon, on the other hand, the amount of transformation corresponds with the amount of material replaced, and is equivalent to the degree of functional recuperation. The more invariably and the more completely an organ replaces its consumed energies with new materials, the more thorough is its functional power; the two great conceptions of modern therapy, exercise and rest, have, I believe, a far-reaching significance for this subject. The exercise causes the replacement of material to the fullest extent, while the rest gradually increases the replacement of material but always within natural limits.

The replenishment of a consumed substance, not only albumin, but also oxygen, is performed by the heart during its periods of rest between the individual muscle contractions; that is, during the diastole. Therefore, every retardation of the cardiac function affects most the diastole and least the systole; and with the length of the diastole the opportunities for nourishing the heart increase. That this really occurs during diastole can be ex-

perimentally proven. A heart which has been artificially slowed for a time by stimulating the pneumogastric nerve and, in consequence, has its diastolic periods lengthened, becomes much more functionally active than if such artificial retardation had not taken place. The great importance of the pneumogastric nerve can therefore be seen by the increase of the diastolic period of rest and the cardiac recuperation caused by it. As increased demands upon the heart cause it to show its over-exertion by an increased activity, and as its exhaustion and lowered nutrition are signified by a subnormal number of pulse beats, so does also the return to the normal number of pulse beats show that the increased consumption of material has been replaced and that a complete recuperation has occurred. This can be shown. If such great demands are made from a heart that, even after their removal, the increased cardiac activity persists, the frequency of the heart, provided the work is again renewed, will far exceed that occurring when the first work was imposed—a sign that the heart had not yet been in a state of normal activity, and that its consumed material had not yet been entirely replaced. In order to employ for diagnostic purposes the sign of complete cardiac recuperation, as evidenced by the return of heart frequency to normal, it will be necessary to definitely determine the normal functional activity of the heart by its normal beats; a starting point for such an investigation, however, cannot be selected *ad libitum*, as the functional power of the heart is influenced by too great a variety of factors. In every case the absolute heart frequency must to a certain extent be ascertained as a starting point, and, if possible, with the individual entirely exempt from all secondary stimuli; and this normal number of heart beats can be best ascertained during the night rest, as during that time there can be eliminated all the stimuli which generally affect the heart, either from without or within the body. Under certain conditions the number of pulse beats during the night may be taken as a starting point; but ordinarily it will suffice to ascertain the number of pulse beats with the patient in a recumbent position. This subject has been more closely investigated by Schapiro (1), Hasenfeld (2) Minassian (3), Graüpner (4), and Langowoy (5), who found that there is a marked difference in the frequency of the pulse whether the individual is standing or is in a recumbent position, and that this relationship is particularly conformable to the normal heart. Every individual in a state of cardiac sufficiency, if changed from a vertical position to a horizontal one, shows a well-pro-

nounced slowing of the heart-beat not less than from ten to twelve beats per minute, a retardation which persists as long as the horizontal position is retained. This is also the case with a pathological heart, although quantitatively less marked, independent of the nature of its lesions, as long as it remains in a state of sufficiency; if, on the other hand, insufficiency is threatening, or has more or less already taken place, there will occur, as we have been able to show in a great number of heart lesions, a slowing of the pulse while the patient is in the recumbent position; and in cases of marked insufficiency with rupture of compensation the decrease in pulse beats even ceases to be present. In such cases the pulse shows the same number of beats both with the patient in a vertical and horizontal position, and should more intense rupture of compensation occur, the pulse beats even increase in frequency with the patient in a horizontal posture.

Of these different number of pulse beats, the number with the patient in a recumbent position is the normal one; as varied as are the number of pulse beats in the vertical position in individuals without heart disease, as well as in those with cardiac lesions but without ruptured compensation, we nevertheless always find, even if not absolutely definitely, a pulse frequency with the patients in the recumbent position, which fluctuates so little that it may be considered as the normal. This normal number of pulse beats is peculiar to each individual and gives a starting point for the functional tests of the heart as based upon its power of recuperation. For this normal number signifies that the replenishment of material in the heart has completely taken place and that the heart is enabled to completely maintain its individual functional activity. A heart which, after the elimination of all external influences that tend to accelerate its action, immediately returns to its normal number of beats, shows thereby that at that moment the previously consumed material has been entirely and thoroughly replaced.

The problem then presented itself, to ascertain up to what degree a healthy heart is able to replace the consumed substance; that is, up to what degree of performed work it is again able to return to its normal number of beats; and, furthermore, how this recuperation, this replenishment of material, conducts itself when still greater demands of equalization are imposed upon the heart. The large number of experiments in this direction were performed by means of Gärtner's ergostats, all the individuals experimented upon working uniformly and for the same length of time. The apparatus was so arranged that by every turn it represented one, two, three or more Kg., of work performed each turn occupying one second. As has already been determined, the number of pulse beats was always counted with the individual in a recumbent position; with the last turn of the crank the individuals experimented upon lied down horizontally or flat upon a couch placed next to them, and upon which the normal number of pulse beats had been previously ascertained. The experiments were invariably again repeated, and sometimes even three times; only those

results which agreed with each other were taken into consideration, although they almost as a rule tallied, showing that we had to deal with conformable results.

As far as the replacement of the consumed material by the heart is concerned, the following laws became established as a consequence of the experiments: (1) If a moderate amount of work is performed by an individual with a healthy heart and equivalent to between 100 and 200 Kg., the increase of pulse frequency occurring during the performance of this work immediately ceases when work is stopped, and again returns to the normal number. (2) If a greater amount of work is performed by an individual with a normal heart equivalent to between 200 and 500 Kg., the pulse frequency also becomes less, not immediately after the cessation of the work, but nevertheless within a short time, and may even sink to below the normal, only then to return again to normal in two to three minutes. (3) If a still greater amount of work is performed by a person with a normal heart in amounts averaging over 500 Kg., the heart does not return to normal, but persists in its increased frequency; the amount of acceleration and the time of its persistence is dependent upon the amount of work performed; but frequently later on, and after some time, the heart returns to normal after it has, in most cases, but not always, passed through a short period of subnormal frequency.

The replacement of expended material takes place as follows: Every heart may immediately replenish an increase in its consumption of material, but only up to a certain degree. This degree varies extremely in each individual; in a heart with only slight functional power it is quite little, but in a vigorous normal heart, this power is quite marked. Every heart, however, has the power up to a certain degree of imposed work to immediately replace the material that has been consumed in the preceding systole, so that when the increased imposition of work ceases, recuperation at once takes place, and with the individual in the horizontal position, the heart immediately resumes its normal number of beats.

If, on the other hand, the demands made upon the heart exceed the amount that can normally be performed by that organ, another estimate can thereby be established, which is applicable for every heart; for with the increased amount of work the consumption of substance is not entirely replaced during the diastolic periods of rest, although equalized to a greater part. Invariably after such a procedure it is observed that the frequency of the heart sinks to below normal, but only for a brief period, that is, for about one, two, or three minutes only, to again assume the normal condition. In addition, where there is an increased amount of work imposed upon the heart, that organ possesses the power, after cessation of the work, to equalize within a short time the deficit of consumed material, which still exists; and this equalization is accomplished by the heart in that its frequency of beats sinks below normal, the diastolic periods becoming, in consequence, increased; in a short time recuperation becomes definitely established and normal conditions are again reached. That this subnormal number

of beats is an expression on the part of the heart that an entire replacement of consumed material and complete recuperation have not yet entirely taken place, may be shown by the fact that an amount of work equal to that originally performed, while a subnormal number of heart beats were still present, causes a much more marked increase in the pulse frequency than during recuperation.

If a still greater amount of work is imposed upon the heart, and one which far exceeds the amount under which the heart can immediately replace the consumed material, the heart will retain its increased frequency for a more or less amount of time after the imposed work has ceased. In this case the demands upon the functional power of the organ have been so great that even after the cessation of the external work, the resistance in the capillary system still continues, so that even after external influences have been removed, the heart is still in a state of over-exertion. Only when the increased powers of resistance still present become gradually equalized does the cardiac acceleration cease, the diastolic periods gradually becoming longer and the heart more and more becomes enabled to replace lost material which in this case of over-exertion makes very exacting demands at the expense of cellular materials. Should the heart no longer be able to bring about this equalization, we have under the acute expression of this phenomenon "heart disease due to over-exertion" and when as a consequence a chronic faulty relationship in the functional activity of the heart occurs we have the typical dilatations, which are the expressions of the final yielding of the heart substance, which has been shattered to such an extent that it can never be entirely replaced. Here, as the heart frequency decreases, there is more and more a replacement of material and not rarely the heart beats finally sink below normal, and thus recuperation for the heart is acquired.

These three phases of replenishment can be recognized in every heart as the amount of work imposed upon it becomes greater; and the functional activity of every heart is proportionately greater, the longer the intervals between each of these phases. The greater the number of Kgs. that a heart can master and then again return to its normal number of beats, the greater is its functional power, all things of course being equal, such as the size of the body and general constitution. The latter factors can, however, not always be embraced in definite numbers; the average estimate of a large series of experiments upon individuals with healthy hearts, as I have tabulated and shall report later, show, that under an external work of about 300 Kg. recuperation takes place even during the work; and in these persons the second amount of work required for a transitory decrease in heart beats to result, amounted to 500 Kg. before the normal number was again reached. But how different is the functional power in individuals with heart disease, even if unimportant objective symptoms are present, as for instance in juvenile cardiac disturbances or slight valvular lesions in a state of compensation, where, according to the clinical appearance the heart is in a state of complete functional service. In such cases

an external work of even 25 to 50 Kg. will suffice in order to bring about an acceleration of the heart beat, which only again returns to normal after a long time. These figures only should serve as examples and in no way the normal; for relative values in these cases are more important than absolute ones, if systematic investigations of the recuperative power are made on the same patient.

And this is not very difficult; the investigations require the employment of an ergostat, and whoever has many cases of heart disease to treat ought to be able to include this instrument among his diagnostic apparatuses. The difference in pulse frequency with the patient in a horizontal and vertical position, an examination which should never be omitted, is in the first place of value from a functional standpoint; this difference in the pulse frequency whether it is slight or entirely disappears in itself indicates with great accuracy an impending insufficiency.

If we test the functional activity of the heart in our patients in the manner herein delineated, we will have a simple and accurate auxiliary method for observing and following up the conditions of their hearts; not the anatomical condition, which is of but little importance for therapeutic and prophylactic purposes, but the condition of the functional activity of the organ. Thus we will also increase our therapeutic knowledge; for I know of no way by which the physician may accomplish more in the treatment of heart disease, than when he is still empowered to ascertain and cope with the cardiac condition of his patients, and to apply this knowledge to their treatment, care and habits.

THE PRINCIPLES OF TREATMENT OF TUBERCULOUS LARYNGITIS.*

By ST. CLAIR THOMSON, M. D., M. R. C. P., Lond.,
F. R. C. S., Eng.,
of London, England.

Physician to the Throat Hospital, Golden Square, Surgeon to the Royal Ear Hospital, London.

The statistics of the pathological department of the Brompton Consumption Hospital show that the larynx is affected in over fifty per cent. of the cases which succumb to pulmonary tuberculosis. As 70,000 persons die annually in the United Kingdom from this disease, at least 35,000 of them would have claimed our help in diminishing their sufferings from tuberculosis of the larynx. The statistics of averages warrant us in saying that there are in this country at least 75,000 who require our aid in arresting or easing the progress of tuberculosis of the larynx. The widespread character of this disease is therefore in itself a claim upon our attention; and when we remember the long drawn-out sufferings which may accompany it, and the youth of the majority of its victims, our humanity is keenly stimulated on their behalf.

The moment seems opportune for briefly reviewing the principles which may guide us in the treatment of tuberculosis of the larynx, for not only must we re-adjust older views to the modern light which has come upon the scene, but such an occasion as the present congress rarely occurs for supplementing the experience of the laryngologist by that of the

* From advance sheets furnished by our representative at the Congress on Tuberculosis, London.

general physician and the pathologist. That this review is very necessary has been impressed upon me by the perusal of a large number of the most recent text-books on laryngology, few of which contain any reference to the treatment of laryngeal tuberculosis by modern hygienic methods. The frame of mind of many laryngologists is reflected in a recent paper by Dr. Johann Sendziak, in which he makes mention of the "rational—that is, the surgical—treatment"*** of this disease, as if any method of treatment short of surgical was not worthy of being denominated as reasonable, and as if hygiene and rest were of no avail, and the *vis medicatrix naturae* a myth.

Our principles of treatment are guided by clinical experience, but, when available, are based on pathological knowledge. The pathology of tuberculous laryngitis is rendered difficult by the complexity of the anatomical arrangement of the larynx. The varieties in the structure of the mucous membrane and submucosa, the functions it performs, the proximity of tendons, ligaments, muscles, cartilages and joints, the disposition of lymphatics and vessels, the occasional movements required in deglutition and the constant rhythmic action of the vocal cords in respiration, are all points which have to be taken into consideration. While the morbid histology of tuberculosis can be so readily studied in the larynx that Virchow recommended it as one of the best opportunities for observing the process, yet the complicated nature of the larynx renders an investigation of the anatomical conditions an equally important part of our task.

Tuberculous affections of the larynx have been classified under four categories:

- (a) Superficial ulceration commencing from the surface;
- (b) Infiltration, followed by
- (c) Ulceration; and
- (d) Tumor formation, or tuberculoma.

This classification is of course somewhat arbitrary. It is seldom that two or more of these forms are not combined when a case first presents itself. As there is little doubt that in the large majority of cases infiltration precedes every other process, it is deserving of particular study as to its situation. It commences in the subepithelial layer, and when it takes place in regions where the mucous membrane is closely adherent to deeper tissue, and particularly to cartilage—as in the epiglottis, vocal processes, and arytenoids—it is very apt to spread to deeper parts, leading to perichondritis and necrosis of cartilage. Although the mucous membrane of the vocal cords is closely attached to the underlying tissue, the absence of subjacent cartilage renders infection of this part of the larynx a less rapidly destructive process. On the ventricular bands there is still less danger of immediate spread to adjacent cartilage.

Of all the various situations in the larynx the most frequently attacked is that of the arytenoids and the neighboring inter-arytenoid space. Lake found this part affected twice as often as the vocal cords, and

three times as often as the epiglottis and ventricular bands.*

In the early stages of such cases the vocal cords not only show a want of tension, but careful inspection will show that their movements are impaired both in adduction and in abduction. This tendency to remain in the natural cadaveric position (i. e., the position of rest), the inter-arytenoid thickening, and the consequent dysphonia or aphonia, have inclined W. Fowler to look upon tubercular laryngitis as chiefly a joint disease. He supports his view by the record of between forty and fifty autopsies of tubercular laryngitis, and as his knowledge as a laryngologist helped to render these examinations very complete, I think the results deserve careful consideration. "In every case," he writes, "the greatest seat of the mischief was in the immediate neighborhood of the crico-arytenoid joint, and the joint itself was always implicated. The deepest part of the ulcer, when ulceration existed, was always immediately in front of the joint, and the joint not only communicated with the floor of the ulcer, but was also more or less disorganized. In many cases the arytenoid was a loose piece of dead cartilage."**

The pathology of laryngeal tuberculosis requires still further study, but in any case we seem warranted in assuming that, as in other parts of the body the first process is one of infiltration. Universal clinical experience and pathological observations concord in establishing the fact that in a large majority of cases this infiltration first takes place in or about the arytenoid joints. Other parts are occasionally attacked primarily; the epiglottis less frequently than any other.

Leaving now for a moment the pathological aspect of the subject, let us consider it from the result of treatment. Writing in 1880, Morell Mackenzie observed, "It is not certain that any cases ever recover" (p. 383), and he states that he only knew of four in which he had reason to believe that the disease was entirely arrested.***

This view has been somewhat modified in the succeeding twenty-one years by the work of Moritz Schmidt, Krause, Heryng and others. Their work has, unfortunately, diverted attention too exclusively to the possibility of exterminating the disease from the larynx by knife and caustic. Recoveries have, indeed, been claimed under various treatments, but we must remember that arrest will take place in the larynx as elsewhere without any local treatment whatever. When reaction and resistance of neighboring tissues are sufficiently vigorous, the advance of infection is checked by the fibroid change, which is the natural and desirable process of cure. In many cases the recovery is deceptive; partial cicatrization of an ulcer may take place in one part, or retrogression of an infiltration occur in the region visible in the mirror, while the process may be spreading in the depths of the tissues, or in such parts as the ventricles of Morgagni and the subglottic region. Besides, the foreshortened image what we see in the mirror is a very unsatisfactory picture

* Laryngeal Phthisis, London, 1901.

*** "Diseases of the throat and nose," vol. i., p. 383.

of the posterior laryngeal wall—the most important region in tuberculosis—and is always inadequate as regards the parts lying below the cords. Every one who performs a laryngo-fissure, or opens a larynx on the *post-mortem* table, is prepared to find disease invariably more extensive than it appeared in the laryngoscope.

But what remains to us of all the various methods of local treatment which have from time to time been vaunted as curative of laryngeal tuberculosis? Their very number is eloquent of their inefficiency, and although some cases may have recovered under treatment, and many may have been locally relieved, yet we need hardly stop to consider whether the various sprays, pigments, insufflations, submucous injections, or intratracheal injections, had more than an alleviative effect, or whether, in the majority of cases, the irritation and reaction they produced did not far counterbalance any possibility of good.

None of the numerous methods which have from time to time secured some attention have ever appeared to me sufficiently rational to make them worthy of an extended trial. On the other hand, their disadvantages and uncertainties were only too apparent. I have therefore been compelled to appeal to the experience of others on this matter, and in doing so will only refer to what we may term the lactic acid and the surgical methods of treatment.

Applications of lactic acid to the tuberculous larynx have obtained such a vogue in the last ten or twelve years that the method has been applied *à tort et à travers*, practitioners in many cases persevering with it while the patient was being prevented, through its effects, from improving generally, or even steadily deteriorating in health. In many cases I have known of its being applied over unbroken mucous membrane, covering deep infiltrations, or evident perichondritis, the surgeon apparently not stopping to ask himself how this superficial caustic could affect these deep processes, or do more than distress the patient and hurry on the progress of the disease. And now Freudenthal, who used it freely, states frankly that "it ought to be dispensed with as antiquated and barbarous torture of the patients."*

In 1899 Freudenthal subjected twenty-nine cases to surgical treatment without being able to record one single cure.** He then treated his cases of tuberculous laryngitis without curettage, and after a year's observations he wrote: "I believe my patients are just as well and perhaps better off than they would have been with the operation."***

The extensive and trustworthy experience of Jonathan Wright has led him to the following statement: "The permanent radical cure of the local lesion of tubercular laryngitis is not materially hastened by the various methods of treatment in any but an insignificant number of cases."

That a certain number of apparently permanent cures have been effected is undoubted. I have myself verified such a case both before and after treatment, which was shown by Dr. Lack to the Laryngological Society of London,**** but the chief point to realize is that even the most enthusiastic sup-

porters of surgical treatment of tuberculous laryngitis admit themselves that the majority of cases are unsuitable even for attempting operative measures. We must also remember that in this small minority of cases the method is painful and distressing; it cannot but react unfavorably on any general condition; and the result is extremely doubtful.

It seems to me that the treatment of the last decade has been based too exclusively on the bacillus as the one and only etiological factor, and that due regard has not been given to more general considerations.

In indicating the slight and unsatisfactory results which have been gained from the direct treatment of laryngeal tuberculosis I must be understood as only deprecating much of the treatment in so far as it has been regarded as affecting a local cure. Where the progress of the disease—in the lungs and in the larynx—is not stimulated by local interference then many measures are available for symptomatic treatment, and we are well equipped nowadays for soothing laryngeal irritation and cough, easing pain, facilitating swallowing, and thus contributing to the general treatment and the possibility of cure.

We must look elsewhere at present than to surgical measures for a prospect of progress in the treatment of tuberculosis of the larynx. This progress is ready to hand in making an earlier diagnosis of local infection. The present is hardly the occasion, even if time permitted, for me to enlarge on the symptoms of the early diagnosis of laryngeal tuberculosis. Besides, the most detailed description of the laryngoscopic appearances could hardly portray a condition which would be recognized by any but an expert, so slight are the early changes and so variously are they combined. "In general," says Grünwald, "it may be said that it is impossible to teach anyone theoretically how to make a diagnosis from the picture in any given case, because, in order to arrive at a decision, one must first learn the development of many successive pictures by long personal observation. Not the picture of to-day, but that of yesterday, and that of to-morrow, must decide for or against laryngeal tuberculosis."* But it is not only from the laryngoscopic appearances that a diagnosis of early tubercular infiltration, or of even pre-tubercular laryngitis, can be made. We must make a careful and thorough examination of the entire body, and pay careful attention to such symptoms as anemia, anorexia, dyspepsia, loss of weight and strength, hurried pulse, and evening rise of temperature. The previous history of the patient, particularly in regard to hemoptysis and pleurisy, must be taken into consideration, and the family history should not be forgotten. There are many other indications of early tuberculosis, and these, together with the indications for the employment of tuberculin as a diagnostic test, I must at present leave out of consideration. In this way evidence can often be obtained which will complete the diagnosis of a laryngeal condition which might otherwise be treated as a simple catarrh. In the absence of positive confirmatory symptoms and of other adequate explanation of laryngeal symptoms, we must treat suspicious cases by measures that we know now will avert a condition which, once

*** Medical News, New York, 19 Jan., 1901.

**** Trans. Laryngol. Soc., London.

*Atlas and Abstract of the Larynx, 1898.

well established, is almost always incurable. In doing this we are but working along the lines and making the same plea for early diagnosis which has been so forcibly advanced in recent years in the subject of pulmonary tuberculosis.

Once the early diagnosis is made the treatment is exactly the same as that now employed in pulmonary phthisis—the sanatorium treatment in what should practically be the open air, with rest, hygienic surroundings, and good food. To this must be added, more or less, strict insistence on voice rest. This is found to be beneficial in many cases, even when the larynx is not affected. It must be much more so in laryngeal cases, when we realize that in the majority of instances the focus starts near or in the crico-arytenoid joints.

The treatment of catarrhal or obstructive affections of the nose and throat, and of any intercurrent conditions of the larynx, must, of course, receive careful and suitable treatment, and it is, therefore, very desirable that those in medical charge of sanatoria should be skilled in practical laryngoscopy. But the important principle to bear in mind is *primum non nocere*, for even a clumsy examination of the throat may produce more irritation and harm than any treatment can counterbalance.

Briefly recapitulated, the principles to bear in mind in tuberculosis of the larynx are as follows:

1. Pathology and clinical experience show that in the majority of cases the focus of infection is near or in the crico-arytenoid joint.
2. Many cases only present themselves at a stage when the possibility of effecting a cure by local measures is quite untenable.
3. The principle of *primum non nocere*, should be constantly kept before us, as many measures which have been tried in this affection have only distressed the patient and hastened the disease.
4. In the light of present knowledge and therapeutic resources, the most rational principle is to attempt to make an early diagnosis of the disease while in an incipient stage. Any persistent or suspicious laryngeal catarrh should be treated seriously on even a presumptive diagnosis.
5. Once diagnosed, the patient should be treated on the principles laid down in the modern method of sanatorium treatment.
6. Symptomatic treatment should be directed to any irritative, catarrhal or obstructive condition of the air passages.
7. In addition, silence should be enjoined, the disuse of the voice being proportionate to the degree in which the focus of infiltration approaches or interferes with the arytenoid joint.
8. In cases where the situation or extent of disease do not warrant an expectation of complete arrest of the process, treatment should be symptomatic, and in many such cases the sanatorium treatment is uncalled for.

The Duration of Life of the Plague Bacillus in Cultures.—N. K. Schults (*Archiv Biologischesch Nauk*, Vol. VIII, No. 4) found that the bacillus of plague may retain its vitality and virulence on culture media for a period of 4 years. During this time the organism becomes shortened, due to the contraction of the protoplasm, and may assume the form of small, round granules, but takes on an active vegetative growth as soon as favorable conditions present themselves. [A. R.]

THE TREATMENT OF TUBERCULOSIS WITH UREA.*

By ARTHUR H. BUCH, F. R. C. S.,

of Sussex County England

Assistant Surgeon, Sussex County Hospital

It is, I take it, generally granted that the most important factors in dealing with any cure for tuberculosis are susceptibility and immunity.

Jenner first recognized the importance of the immunity of a portion of the community to a particular disease, and eventually his labors have procured the immunity of the rest from that disease.

It was not, however, till comparatively recently that the importance of his work was understood.

All the great workers in this direction, whilst studying susceptibility and immunity, have tended to be drawn in one direction, and that is the preparation of antitoxins, by means of the injection of which into the human body we can either render such immune to, or modify an attack already begun, by the germ peculiar to each disease.

These antitoxins have been prepared from the growth of the different organisms concerned, under various conditions, and the result is that the chemical substances which have been injected into the tissue of those to be protected are powerful alkaloids or toxalbumins differing chemically from any combinations hitherto demonstrated in our organizations.

Now this class of antitoxins have so far proved of greater value in acute specific fevers, such as diphtheria, smallpox, typhoid and bubonic plague, than has the corresponding antitoxin in tuberculosis. But tuberculosis differs in many other respects from acute specific fevers. The former is a chronic disease, the latter are acute.

The tubercle bacillus is one of the family of organisms which are termed infective granulomata, the latter belong to a class which produce their toxic effects in the body without the formation of new growth around them.

The tubercle bacillus has an exceedingly wide distribution, that of the others is, comparatively speaking, extremely limited.

Every one of us has been exposed, some constantly, to infection by tubercle, but comparatively few have developed the disease; whereas of those who, being unprotected either by a special antitoxin or by a previous attack, are exposed to active infection by any of the acute specific fevers, I presume it is safe to say that the great majority would develop such.

In other words, by far the greater proportion of mankind provide a fit soil for the growth of the germs of acute specific fevers, whereas a small minority only are capable of harboring and developing in their tissues the tubercle bacillus.

The majority of us, therefore, possess in our systems some vito-chemical combination or condition which renders us immune to any ordinary dose of infection by the tubercle bacillus, and it follows that that combination or condition must be actively hostile to the bacillus, for we are all exposed to the infection.

This substance, or condition, therefore, whatever it may be, in contradistinction to the antitoxins,

* From advance sheets furnished by our representative at the Congress on Tuberculosis London.

must be such as is neither harmful nor foreign to the human organism. It most probably exists in some in a greater degree than in others; but in any case, if we could induce in the tissues of the susceptible some difference in metabolism so that this substance or condition was introduced into or manufactured in their systems, there can be no manner of doubt but that we should rid the human race of tuberculosis.

It was by the observation that in his experience the gouty were particularly immune to tubercle that induced Dr. Harper, of Nottingham, to prescribe pure urea to the tuberculous with a view to increasing the amount of urea and uric acid in their systems, and it is because of the enormous importance that I believe attaches to this treatment that I am reading this paper.

Dr. Harper has published two papers full of interest in the *Lancet* this year (March 9th and June 15th), in which he mentions many cases of phthisis which, being apparently incurable, have recovered. I would draw attention to the fact that Dr. Harper was induced to try this treatment by the observation of the peculiar immunity of a small part of the community, namely, the gouty, to tuberculosis; in other words, for reasons similar to those which induced Jenner to try vaccination for smallpox.

I think it is an extremely interesting fact to note that urea, in the shape of urine, has been taken from time immemorial as a medicine, and that the natives of India are at present using it in this way.

On the books of the Calcutta Zoological Gardens is an item, in the receipts, of £60 annually paid for the urine of the rhinoceros, which I am informed, by the gentleman who told me of this fact, the natives buy and take internally in cases of lung disease.

Does urea benefit cases of tuberculosis; if so, how and why?

It is extremely hard to convince anyone of the value of a drug who has not tried it himself, but from the extraordinary results I have myself seen I have not the slightest doubt in answering the first question with a decided affirmative as regards some cases.

As the treatment is still on trial and in its infancy, the answer to the second must necessarily be uncertain. The following facts, however, will, I believe, be found to have a bearing on the case.

Urea is one of the end products of nitrogenous metabolism, *i. e.*, of the oxidization or reduction of proteid matter, and the medium in which most of the nitrogen excreted from the body is carried away in the urine. Its chemical formula is $\text{CO}(\text{NH}_2)_2$, and it is isomeric with cyanate of ammonium $(\text{NH}_4)\text{CNO}$, from which it can be prepared synthetically.

Urea is formed, according to our latest knowledge, in the spleen, lymph and secreting glands, but principally by the liver. It is excreted by the kidneys.

Urea has lately been produced from proteid material in the chemical laboratory, but by processes which cannot be the same as those which go on in the body.

The original source of the nitrogenous matter, which eventually supplies urea, is, of course, the proteids consumed as foods.

"These proteids are the most important sub-

stances," to quote Dr. Halliburton, "that occur in animal or vegetable organisms. None of the phenomena of life occur without their presence;" and yet we do not know their exact constitutional formula, nor, indeed, do we know whether they exist as such in living protoplasm, "though they are always obtained by subjecting living structures to analytical processes."

"All that we know with certainty is that many different substances may be obtained by the decomposition of proteids. How they are built up into the proteid molecule is unknown. The decompositions that occur in the body are, moreover, different from those which can be made to occur in the chemical laboratory, hence the conclusion that living protoplasm differs somewhat from the non-living proteid matter obtainable from it."

With this state of uncertainty it is evidently impossible at present to understand precisely why and how urea can act beneficially in tuberculosis, or what changes exactly take place on its re-entrance into the body. Again we can only deal with facts.

Urea contains nitrogen, as do these all important proteid matters.

During the period of growth and development less nitrogen is eliminated from the body than during the decline of life. The balance of nitrogen, therefore, with absorption at one end of the scale and elimination at the other, plays an important part in the cell activity and vito-chemical constitution of the body. If we can prove that urea splits up during the process of absorption, and that its nitrogen is assimilated, it can only be assimilated in the metabolism of protoplasm. We shall then have established the curious fact that an apparently waste product, the result of a process of reduction by oxidization of protoplasm, on being passed through the mill, so to speak, a second time, assists in building up tissues similar to those from which it was originally derived. The proof that urea was decomposed in the process of absorption and assimilation, and that its nitrogen is wholly or in part retained in the body, can only be ascertained with certainty by elaborate processes of analysis.

With the general practitioner this is, as a rule, impossible, owing to lack of experience, time, and apparatus. But more experiments, including estimation of total nitrogen eliminated, will be necessary before definite statements can be made. Dr. Harper mentions in his paper that the urea in most cases is not increased. In appeal a few notes on this subject which I have obtained, from which it will be seen that the urea is more often below normal than above. For the estimation of the uric acid I have to express my best thanks to Mr. Gomess, of South Kensington, and for the urea to Mr. Tweedy, of the Sussex County Hospital.

Dose Urea.	Average Total Urine	Average Urea.	Uric Acid.	Age of Patient.
1 30 grs. t.i.d.	41 oz.	21 per cent	01 per cent	32
2 40 " "	50 "	11.9 "	before taking urea	55
3 1 dr "	43 "	16 "	after " " "	36
4 20 gr "	33 "	15 "	" " "	12
5 10 " "	Uncertain.	25 "	" " "	25
6 30 " "	" "	7 "	" " "	18
7 20 " "	35 oz	22 "	" " "	12
8 25 " "	36 "	25 "	" " "	15

Mr. Gomess has also very kindly worked out the total amount of nitrogen in the first two cases with the following result:

1st. By Kjeldahl's method 5 c.c. urine=37.8 c.c. Nitrogen.

2nd. By Kjeldahl's method 5 c.c. urine=36.4 c.c. Nitrogen.

Total amount of nitrogen in 45 ozs. urine in first case equals 8640 c.c., and in 50 ozs. urine in second equals 9245 c.c. Mr. Gomess adds, "My own opinion, is, if I may judge from above figures, that the nitrogen eliminated in the urine is much less than the amount given in the form of urea."

The percentage of nitrogen in urea to that in flesh is as 46 2-3 to 16. It will be seen that the nitrogen taken in the food has to be added to that taken in the urea, and it seems plain that the extra nitrogen has not been excreted in the urine, at all events in the two cases quoted above.

A short description of some cases which I have treated in this way is as follows:

CASE 1.

Man, aged thirty-six. Was deserted as an infant, and suffered from tuberculous disease of left ankle and both elbow joints during childhood.

Amputation was performed below the knee for the ankle joint disease, and double arthrectomy of elbows at age of ten to eleven.

Twelve years ago lupus commenced in nostrils and spread with some rapidity to face and forehead. In spite of various treatment the disease progressed, and the following was the condition when on the 26th of March last I commenced treatment with urea.

One large ulcer occupied an area, around which I will trace an imaginary line commencing at the centre of hair of forehead to a point half an inch above the outer end of each eyebrow, then inwards along the upper border of the eyebrows to a point above the root of the nose. The nasal bones had necrosed and come away, leaving a round hole leading into nasal cavity. Ulceration existed on both cheeks, and the left lower eyelid had gone. From the outer edge of the ulcer on one cheek to a corresponding point on the other measured six and a half inches. In the centre of the face was a bridge of tissue, representing remains of the nose covered with epithelium. Below this was another irregular hole where had been the nostrils. Ulceration was present over the area where the upper lip had existed, most of this having disappeared. The edges of these large ulcers were very much raised, irregular nodules composed of chestnut-colored, apple-jelly-like matter, sharp cut towards the ulcer and gradually sloping down towards healthy skin. Some of the nodules stood three-sixteenths to a quarter of an inch above the level of the ulcer.

Inside the nose one large cavity existed, the septum, part of the ethmoid and most of the turbinated bones having disappeared. The walls of this cavity were in a similar condition of ulceration to the external parts. The granulations over all the ulcers were unhealthy, and showed no signs of healing except at the parts most distant to the spreading edge. Here such attempts were very feeble. There was very much discharge of a thin, purulent character. So much collected in the naso-pharynx that the pa-

tient almost choked every morning before he could get rid of this.

The general condition was poor and the man most miserable.

On March 25th, 20 grs. urea t.d.s. ex Aq. Menth. Pip. 1 oz. were prescribed.

April 25th. Granulations much more healthy, edges distal to spreading edge healing. Discharge very much less. Spreading edges not so raised. 30 grs. urea t.d.s. prescribed.

April 30th. Ulcers quite healthy. Edges less raised. Healing up rapidly from parts first affected. 40 grs. urea t.d.s. prescribed and Maltine $\frac{1}{2}$ oz. t.d.s.

May 7th. Edges of ulcers flat. Line of healing. Epithelium from these. 50 grs. urea prescribed.

May 27th Ulcers nearly all healed. Little nodules left on temples and on upper lip.

June 4th. 1 drachm urea t.d.s. prescribed.

June 11th. Nodules on temples disappeared, that on lip disappearing.

At present time the forehead is practically healed, a small sore on the lip, owing to the local application not suiting it, formed, and has not yet healed again.

The local application during the whole treatment was not changed, nor was patient's diet or way of living. His diet was chiefly potatoes, and had been for years. His mode of living was to keep in one room all day, and come out to sell papers in the evening.

CASE 2.

Man, aged thirty. Father died of phthisis. Nine years ago lupus commenced on right side of face, and gradually spread round to under chin, healing behind as it traveled, except at junction of lobule of ear with face.

Four years ago left side of nose and face was attacked.

The patient also developed dactylitis in second finger of right hand four years ago, this eventually healed with deformity, leaving a tuberculous dermatitis on back of right hand.

June 24th. Urea grs. 30 t.d.s. was prescribed. The patches were then all raised and nodular and covered with scales and scabs, under which, on removal, was the jelly-like granulation tissue.

The most marked patch was on left side of nose, as big as half-a-crown.

July 2nd. Very great improvement. The raised areas are level at the circumferences with surrounding skin, and are less red. Sensation in them has improved. The scabs are now limited to central parts. Urea continued.

July 9th. The skin, which was stiff and hard where it was affected, is getting pliable and softer. The patches of lupus are melting away. Patient is still under treatment.

CASE 3.

A man, *act* twenty-two. Glands both groins began to swell a month ago. No apparent cause found. One gland on left, softening in centre, opened, and typical tuberculous caseous gland substance scraped out. Other glands enlarged, and on the right, one softened. Urea grs. 30 t.d.s., increased gradually to grs. 40 t.d.s. The patient, who looked poor and thin, rapidly improved, and the glands did remarkably well; the one that was first scraped out healed in

three weeks, the other enlarged glands undergoing resolution. The man was at work in three weeks. Diet and general conditions fairly good.

CASE 4.

Woman, *act.* thirty, married. Family history of phthisis. Glands enlarged for fifteen years left side of neck. Operated on four years ago, and again by myself six months ago, when I removed glands from base of skull to clavicle. Recurred two months ago, just under angle of jaw, and when put on urea, there was a large mass of glands in this situation pushing out the skin and looking as if they must come through. After urea grs. 35 t.d.s. for six weeks, these glands have almost disappeared, and the woman is better in every respect. Still under treatment. Diet and conditions fair.

CASE 5.

Boy, *act.* fifteen. History of phthisis. History of two months pain and weakness in right elbow. The joint was almost fixed at a right angle, and very painful. All the hollows were filled with typical soft tuberculous granulation tissue in the synovial membrane. Wasting of forearm half inch. No history injury.

July 2nd. After urea gr. xx t.d.s., and rest on a splint for ten days, patient was much improved. Could flex forearm, so that fingers could touch shoulder. Extension not so good. Pronation on arm and supination nearly perfect. All these movements done without pain.

The swelling about the elbow was very much diminished.

July 9th. Swelling about elbow has disappeared altogether. Movements as before, but extension from full flexion to within forty-five degrees of full extension. Still under treatment. Diet and conditions fair. Urea 1.4 per cent. Average total quantity urine, 36 ozs.

CASE 6.

Girl, *act.* eighteen. History of phthisis on mother's side. Lupus commenced two years ago in nostrils. Glands enlarged in both submaxillary regions and broke leaving ulcers. In the left nostril only the orifice could be seen, owing to granulations of jelly-like material and swelling of the parts. There was a typical patch of lupus about the left part of the upper lip and cheek.

July 9. After a month with urea grs. xxx t.d.s. the left nostril can be examined with ease and the septum seen to be occupied by a healthy granulating ulcer. The lupus on the lip and cheek have all but faded away, and the tuberculous ulcers in the submaxillary regions have healed. Patient under treatment. Diet and general conditions poor.

CASE 7.

Patient, *act.* twenty-two. Many enlarged glands on right side of neck, together with large tuberculous abscess under sterno mastoid from the softening of one. The abscess was opened, washed out and stitched up, no drain being used. In six weeks' time, after an average dose of 30 grs. urea three times a day, the whole of these enlarged glands had entirely disappeared. There was a history of phthisis in this case, but diet and general conditions were very good.

In all other tuberculous cases in which I have given urea myself I am having, or have had, good results.

Not a single untoward symptom has arisen; on the contrary, the action has evidently been in many cases that of a nervous tonic.

In conclusion, I will draw attention to the fact that Dr. Harper has already laid stress in the *Lancet* on the facts that the tubercle bacillus in the laboratory grows best on media that are of low nitrogenous value, and that in the lower animals it attacks the herbivorous rather than the carnivorous.

The cow is an interesting animal, from this point of view, as it is the animal more often attacked by tuberculosis than any other. Here we have a large amount of energy expended in procuring a sufficiency of nitrogen from herbs and a large loss daily in proportion in the casein of milk. This process of extraction of nitrogen goes on far beyond the ordinary period of lactation. It would seem that there may well be a relationship between nitrogenous absorption, assimilation and elimination, and the tubercle bacillus in this case.

I sincerely hope that elaborate experiments will be made with urea in the near future and that it will be widely tried in all forms of tuberculosis.

Personally I believe that Dr. Harper's discovery will lead to a revolution in the treatment of this disease, and that many cases which have been considered hopeless in the past will be cured in the future.

UNDILUTED MILK IN THE CHRONIC GASTROENTERITIS OF RACHITIC INFANTS.*

By MAURICE OSTHEIMER, M. D.,

of Philadelphia.

Physician to the Children's Dispensary, University of Pennsylvania; Dispensary Physician to St. Christopher's Hospital for Children, Philadelphia.

In the address made by Dr. Holt at the April meeting of the Pediatric Society, he mentioned that he had obtained good results in some cases of chronic gastroenteritis from the administration of concentrated food. Experience in the Paris hospitals has shown me that babies over five months old can thrive upon undiluted milk in small quantities. In half a year's service at the Children's Dispensary in the University Hospital I found but three infants, aged respectively eight, eleven and thirteen months, who might be expected to improve upon such food. In not one case had breast milk been given over three months, after which all sorts of patented foods and diluted milk formulae were tried. They were all more or less rachitic and asthenic, examples of that extreme emaciation which is seen in infants habitually overfed with, perhaps, too diluted food.

In the first case, Sadie G., the patient, weighed 8 pounds at birth. She had been nursed for one month, then took Horlick's food, Mellin's food, and condensed milk, in turn. Gastroenteritis naturally persisted upon this diet. Different grades of diluted milk were then tried, all without success. Signs of rickets and inanition had appeared by this time, and four physicians, to whom the mother applied, gave up hope of saving the child. When the mother brought the child, then 6 months old, to the dispensary, she weighed 7½ pounds. She was taking a diluted milk formula, 5 ounces every three hours, the approximate percentage of which I made out to be 2.5% of fat, 6% of sugar, and 0.60% of pro-

* Read before the Philadelphia Pediatric Society, June 11, 1901.

tolds. She vomited immediately after feeding, cried continually, and had 4 or 5 greenish yellow stools daily. She was very thin and anemic, with somewhat square head, wide open fontanelle, slight rosary, and prominent abdomen, but no epiphyseal enlargement or bowing of the long bones. After a day upon barley water, a mixture of fat, 4%; sugar, 6%, and proteids, 1%, was tried, 3 ounces every three hours. The vomiting diminished, but the bowels remained unchanged. She improved, however, and at 7 months weighed 11 pounds. As there was no vomiting, a formula of fat 4%, sugar 7% and proteids 2%, was given, 5 ounces every three hours. During the succeeding 6 weeks she not only did not improve, but, from the crying, developed an umbilical hernia. I discovered that her mother had increased the quantity of milk given every three hours to 8 ounces. Believing that a smaller amount of a stronger milk would help her, I ordered undiluted, unboiled milk, 4 ounces every three hours, with from two to four tablespoonfuls of boiled water between bottles. She was then 8½ months old. At 10 months she weighed 16 pounds, and no further signs of rickets appeared. She had grown larger, stouter, and constipated. Her mother brought her last at the age of 15 months, when she weighed 25 pounds. The milk had been increased, while abdominal massage, enemata, and glycerin suppositories relieved the constipation. Her first tooth appeared at 11 months, and she had eight teeth at 15 months. The amount of milk was decreased, and fruit, cereals, and green vegetables were added to her diet list.

The second case, Maggie McM., came to the dispensary at 11 months. She was an eight month baby, and had vomited frequently since birth. Diarrhea was constant, in spite of all foods tried. There was no history of tuberculosis or syphilis on either side of the family. At 11 months she was taking 4 ounces of a mixture containing approximately 3% fat, 6% sugar, and 2.5% proteids, every two hours. Her head was large and square, the fontanelle wide open and the eyes deeply sunken. The cervical and inguinal lymph-glands were much enlarged, and there was faint dulness anteriorly, to either side of the sternum, in the second interspace. Eustace Smith's sign was present. She was chicken-breasted, with a well marked rosary. There was slight epiphyseal thickening with some bowing of the tibiae. She perspired freely and moaned a great deal. Her temperature rose in the afternoons as high as 102°F. After a day upon barley water, undiluted milk, unboiled, was given, 4 ounces every three hours, and orange juice twice a day. She thrived so well upon this that it was two months before her mother brought her again. Then she had aphthous stomatitis. She was pale, but had grown stouter. The enlarged lymph-glands, still palpable, were no longer visible. The stomatitis, in spite of vigorous treatment, spread to the pharynx, and laryngitis followed. Klebs-Loeffer bacilli were not found in the cultures made. She recovered, and has grown well since. She is now 18 months old, and runs about. Her milk has been increased to 6 ounces six times a day, and table food is just beginning to attract her attention. Her square head and faint rosary are the only signs of rachitis remaining. She has not been at all constipated. The symptoms of enlarged bronchial glands have all disappeared.

The third case, Martin K., was nursed only three months. As his mother was paralyzed, condensed milk was then given for five months. From 8 months until I saw him at 13 months, he took large amounts of a mixture containing 2/3 milk and 1/3 water, given much too often. His head was large, with prominent forehead, the frontanelle open; there was some epiphyseal thickening, with a rosary. Besides, growing backward from the coccyx was a rudimentary bony tail, 1/2 an inch long, which had almost broken through the skin over it. He rarely vomited, weighed 9 pounds, and looked asthenic, thin, and pale. Undiluted milk, 3 ounces every three hours, was ordered. Two months later he weighed 12½ pounds. At 17 months he weighed 16 pounds and had 12 teeth. When I last saw him, he was 21 months old and weighed 24 pounds. The skin over the rudimentary tail had become normal, showing a dimple 1/4 of an inch deep. The bony process was still palpable beneath the subcutaneous fat. He was living in the country, and took three pints of milk daily. The signs of rickets have all disappeared. He seems a fat, healthy infant, is just beginning to walk, has 16 teeth, and is not constipated.

The only drugs given in these cases were cod liver oil, both internally and by inunction, and increasing doses of syrup of the iodide of iron. I have seen A. B. Marfan, at *L'Hôpital des Enfants Malades*, give undiluted milk to children over five months old, but at longer intervals and in smaller doses than a diluted milk formula. E. Schlesinger (1) has recently published a table showing the improvement which occurred in a number of infants upon substituting undiluted milk for diluted milk formulae.

G. Variot (2) has just reported a case of infantile scurvy in a child of seven months, from the use of "*lait maternel*," cured simply by giving undiluted milk. To resume, then, in the cases reported, from the varied and probably diluted character of the food, rachitis with gastroenteritis of months duration developed. It seems but just to conclude that there are many little patients in whom long standing gastroenteritis is due to the ingestion of too large a quantity of a too dilute food. In such cases the main indication will be small amounts of pure milk, unboiled and undiluted.

UNUSUAL AFTER EFFECTS OF A SNAKE BITE.

By LAWRENCE E. HOLMES, A. B., M. D.,

of Biltmore, Asheville, N. C.

I report this case on account of the curious after-effects of a snake bite.

The patient was a woman, 21 years old, and married. While stooping down to pick up some weeds she was bitten by a snake on the right forearm, on the ulnar side, about two inches above the wrist joint. I saw her about half an hour after it happened. Two minute punctures (teeth marks) were visible in the above mentioned position, and the area around them was red and swollen.

Tobacco-juice—a home remedy—had already been applied. The woman did not know what kind of a snake it was that had bitten her, though she thought it was a garter-snake, a non-poisonous variety. In this uncertainty I gave her the benefit of the doubt, though being out in the country at the time, there was not much choice in the method of treatment, which consisted in circular compression of the forearm above the wound, incising the latter, which was allowed to bleed freely, and was then washed out with a 10% carbolic acid solution, and the same solution used on the dressing. The arm was then put up in a sling, whiskey was given internally, though there were no marked constitutional symptoms, except some faintness. Pain became severe, morphia being required, and continuous cold applications were made to the forearm. In a day or two the swelling subsided, and the numbness, of which she had complained, disappeared, though the pain in the forearm and axilla continued. On the fifth day she noticed some weakness and numbness of the hand, which prevented her buttoning her clothes, and the next day she came back to me. The forearm was slightly swollen, tender and red anteriorly, and she complained of pain in the arm and axilla, though no decided enlargement of the axillary glands could be made out. The wound was in good condition. On careful examination I found that there was complete anesthesia of the hand and wrist, anteriorly, below the position of the wound; posteriorly, below a line corresponding about with the carpo-metacarpal articulation. Within this area, even under the nails, a pin stuck in deep enough to draw the blood, could not be felt. Temperature sense was also lost over the same area. The movements of the hand were impaired, showing loss of power in the hand muscles. Two days later I saw her again. The forearm was less swollen, the pain and tenderness had also diminished. Anteriorly the anesthetic area had not changed, posteriorly, it included the whole surface below the level of the wound. In a few days, under no special treatment.

(2) *Bulletins et Memoires de la Société Médicale des Hôpitaux de Paris*, March 7, 1901.

sensibility and muscular power began to return, and shortly afterwards the hand and forearm had regained their normal condition.

The interesting point in this case is the cause of the motor and sensory paralysis. The possibility of the nerves having been wounded in the incision being out of the question, it lies between hysteria and a toxic neuritis, somewhat similar in character to that occurring in diphtheria, caused by the serpent venom. The fact that the paralysis did not appear for four days after the infliction of the wound, and the absence of any other signs of neuritis, would favor the idea that it was of hysterical origin; the fact that it came and went gradually, that it affected only those movements of the hand controlled by the muscles of the hand, and not by those of the forearm; in other words, that it affected those muscles whose supplying nerves lay in the neighborhood of the wound; and the absence of any neuropathic tendencies in the woman, would favor the diagnosis of a toxic neuritis.

PRESSE MEDICALE.

1. Spasmodic Constipation. ALEXANDER MAZERAN.
2. Painful Anal Fissure Treated by Electricity.

A. ZIMMERN and A. LAQUERIERE.

1.—While constipation generally is accompanied by atony of the intestinal muscle, it is possible for constipation to occur with spasmodic contraction of the intestines. Spasmodic constipation may be essential or dependent upon an organic condition, of which it is but a symptom. This condition may be due to a genito-urinary affection, to abdominal injury, to calculi, to localized inflammation of the intestine, to foreign bodies, or to intoxication. The essential form is found with the neuroses, due to a want of physical energy. The spasm is either the result of this lack of energy in the nerve centers, or the consequence of the hyperexcitability of the peripheral nerves. It may occur with large abdomen and hemorrhoids, in a well man of sedentary occupation; with hollow abdomen and dyspepsia, in the pale, atonic, listless individual; or with normal abdomen, tympany and pain, in women, as a rule. A crisis comes on suddenly, the symptoms being sensations of constriction, expulsion, and torsion of the intestine. The patient complains of feeling a moving ball in the intestines. Other nervous symptoms accompany the pain of the attack. The rest of the time constipation is the main symptom, though there may be flatulence and hicough. Enteroclysis, which is given easily when the constipation is due to atony, is impossible when the spasm is total; or when the spasm is but partial, the liquid may all be retained. Mucocomembranous enterocolitis always co-exists. The prognosis may be serious. The treatment consists of antispasmodics locally, belladonna, assafetida, etc., abdominal douches, baths, and compresses, enteroclysis, and electricity; antispasmodics generally, hygiene, tonics, hydrotherapy, etc.; and diet, mild laxatives, and mineral waters, as adjuvants. [M. O.]

2.—Electricity in the treatment of anal fissure was only attempted three years ago. Surgical treatment alone had hitherto caused a cure, by dilatation of the anal sphincter. After a review of the literature, Zimmern and Laquerrière report the histories of seven cases treated with rapidly interrupted electric currents. Only four of these patients came regularly, but they were cured. All were or had been syphilitic. The apparatus employed is described in detail. Superficial insensibility is produced by the application of the current, followed by a profound diminution of the senses of excitability and irritability. Thus all spasmodic contractions cease, and cicatrization can occur. [M. O.]

June 26, 1901. (No. 51).

1. Exploratory Incision in Doubtful Tumors. QUENU.
2. The Practice of Medicine in China. E. JEANSELME.

1.—Quenu believes that exploratory incision should be performed in patients in whom malignant tumors are suspected. For it will be too late to operate after adhesions,

enlarged glands, rapid increase in size, cachexia, etc., appear. Especially is this true of tumors of the breast. It is thus possible to procure enough to diagnose the nature of the tumor. After describing a number of cases treated thus, Quenu states that exploratory incision will indicate the correct operation to be done. [M. O.]

2.—In China, treatment consists of three sorts of drugs, the curative, the preparatory, and the reparatory or reconstructive remedies. For ailments due to excess of vital heat a cold drug is given, and vice versa. Rock crystal is given for blindness; ginseng, the roots of which resemble the male genitalia, is given for sexual impotence. For most diseases the horns of the stag or rhinoceros, with ginseng, are given. Gold leaf, human bile and urine are often employed. Iron, arsenic, mercury and sulphur are often well prescribed. Ergot is widely used for producing abortion; cantharides as an aphrodisiac. Scarification, cauterization, and acupuncture are all much used in China. Massage is universal. Warm water applications are employed generally after hard work, for fatigue. Any one may practice medicine or pharmacy; he must only attend patients with a practitioner for a short time, and must have read a few Chinese books upon the subject. A son will be taught by his father, thus keeping secrets of treatment in the family. Specialists on all subjects are numerous. Only one visit is made, the physician waiting for another call before going again. Women especially object to a physical examination, even when parents and husband consent. Jeanseime describes the ideas of a number of Chinese physicians he met. A few have added exact observation to the ridiculous theories held. Anatomy and physiology are all lacking. They receive 4 or 5 cents a visit. Jeanseime believes that when the Chinese realize the methods of modern medicine, they will not only copy them, but develop them further. [M. O.]

1. A Short Atypical Epidemic of Pest.

ROBERT JACQUES and

J. CONSTANTIN GAUTHIER.

1.—In August, 1900, a steamer from Constantinople reached the Pirou Islands, where the Marseilles Lazaretto is situated, with three supposed cases of pest. Two other cases had debarked a few days before, at Clazomene, one of whom had been taken ill the day before, the other two days before. They both recovered without their buboes suppurating. They undoubtedly had the pest. The first case which came to Marseilles arrived on the third day of his illness. He had himself injected 50 c.c. of antipest serum twice. He was given normal salt solution and the Yersin serum. He recovered after three weeks of fever. The man who had been looking after him showed slight symptoms, which were cured in a week. Then a stoker died with the pest, after vague symptoms of only a few days' duration. Three other mild cases of mixed malaria and pest infections were seen. Whether the pest case infected the rest, or whether the rats were responsible for the epidemic, is unknown. The only death occurred in the case not treated with antipest serum. Intravenous injections of antipest serum were shown to be a very simple and beneficial proceeding. [M. O.]

JOURNAL DE MEDECINE DE BORDEAUX.

1. Separation of the Nail.

W. DUBREUILH and D. FRECHE.

2. Supra-vaginal Hysterectomy with Phlebitis.

L. VERDELET.

1.—Separation of the nail from its bed occurs secondarily in many ungual affections, such as psoriasis, eczema, onychia, etc. There is always some hyperkeratosis at first, with desquamation of the bed of the nail. Seven case-histories are given in full, some due to trophic disturbances, others being purely local. In one case the separation occurred with painful attacks; in the next three, it was trophic; and in the rest, no cause could be found. [M. O.]

2.—Verdelet reports two cases of supra-vaginal hysterectomy for fibromata and double hydrosalpinx, in whom phlebitis of the left leg developed about three weeks after operation. There were but these two cases of phlebitis out of five cases operated upon by this method. Verdelet believes this to be due to insufficient drainage by this method, and he prefers to perform total hysterectomy, either abdominal or vaginal, on that account. [M. O.]

The President's Death.—In the shadow of this great national bereavement any mere disappointment to professional pride that arises from the unforeseen result must sink into insignificance. Yet the case of President McKinley has assumed immense proportions from a merely surgical standpoint, and will doubtless rank for a long while as a precedent of exceptional importance. The disastrous end—so sudden and so disillusioning—came to no class in the community with a greater shock than to the medical profession. There may have been—and there were—conservative and cautious minds in the profession who hesitated from the first to follow the lead of optimism that characterized the progress of the case, but it is safe to say that the majority of physicians and surgeons were buoyed up with the inspiring hope that the wounded Chief Magistrate was to live, and to owe his life to the achievements of modern scientific surgery.

But man proposes and God disposes. All that human skill, knowledge, promptness, daring and an overmastering sense of duty could accomplish, were devoted to the case of the President. There is nothing to retract, to explain or to apologize for in all that has been said or done by the brave and devoted staff who gave their best knowledge and skill to the saving of that valuable life. An unforeseen contingency, such as may happen in any surgical case; an unavoidable constitutional defect, such as may appear in any man well passed middle life; these were the undoing of the best planned and best executed operation of which the case permitted. From the technical standpoint we believe that the case is not open to adverse criticism. Some of its purely scientific aspects we shall discuss further on.

To the surgeons and physicians who bore the burden of this heavy responsibility we extend acknowledgment and sympathy. They performed a grave public duty, and their names will always be honored by an appreciative people.

The memory of the distinguished patient and martyr needs no eulogy from us. The members of the medical profession, who encounter death in all its forms, will pay tribute to President McKinley's fortitude in the face of a great tragedy, his resignation in suffering, and his nobility in death as in life.

The Autopsy.—The report of the autopsy in President McKinley's case is admirably brief, clear and free from technicalities. This is most fortunate, as it is desirable on every account that the public should fully understand it. From the medical standpoint it perhaps leaves some things to be desired. For the pathologist it is not exhaustive, and some queries are bound to arise; some speculation is sure to occur in an attempt fully to interpret it.

The essential point in the case was the occurrence of gangrene. This process had occurred not only in and around the wounds in the stomach, but also along the track of the penetrating bullet. Even the superficial wound made by the first bullet was, according to one observer, not in a healthy condition, but was also the seat of beginning gangrenous change. With all this there was no formation of pus nor any evidence of a distinct septic or pyemic infection. Contrary to what had been thought, two of the viscera beside the stomach were found to have been wounded. One of these, the kidney, was only slightly abraded, and its injury does not seem to have been responsible in any way for the fatal result. The other viscus involved was the pancreas, and this injury was probably of far greater significance. In our review of the case last week we spoke of a possible wound of the pancreas, and pointed out the fatal consequence of such a wound.

In the light of the autopsy the determination of the cause of such an unusual sequela as widely disseminated gangrene, must be largely a matter of speculation. As such we do not intend to enter fully into its discussion, and yet there are a few considerations that suggest themselves in this connection.

The escape of the pancreatic fluid and its constant bathing of the wounded parts are not to be ignored. In disease of the pancreas, with formation of pus, gangrene has been observed (Starr, *Pepper's System of Medicine*, Vol. II).

Again, the occurrence of gangrene, following upon wounds and some suppurative lesions, such as boils and carbuncles, has been observed in diabetes. We have no evidence that such a complication existed in the President's case. The only suggestion of it has come from newspaper reports and other unauthor-

ized statements. Hence we are not entitled to adopt such an interpretation, and must put it aside.

The heart muscle was thin, a condition in which there is always the suggestion of some muscular degeneration in the case of a man almost 60 years of age. The state of the coronary arteries, a thickening of which would induce beginning muscular degeneration and dilatation, is not recorded. The state of the pulse from the first was suggestive of shock, acting upon a somewhat weakened heart.

From the autopsy it is evident that the best directed surgical skill was doomed from the beginning to be frustrated.

The Abdominal Wound.—The gravity of the wound, arising from the important and vital structures in its close proximity, was recognized by abdominal surgeons, and it was the general belief that forty-eight to seventy-two hours must elapse before a reasonable hope for recovery could be entertained. It was, therefore, a source of intense satisfaction, not only to the medical attendants, but to the whole medical profession, that this limit was reached with all the symptoms—save one—pointing towards a rapid and uncomplicated recovery. The rapidity of the heart's action was not accounted for. The steady improvement in every other respect justified the hopeful view of the case that was taken by those in charge. As we pointed out last week a wound of the pancreas did not seem to be indicated because of the favorable progress of the case. The next contingency, a wound of the kidney, was contraindicated by the absence of blood in the urine. The fact that, in spite of a wound of the pancreas, the patient lived for a week, is one of the most noteworthy in the case. The wound of the kidney was so slight as to be insignificant. The fatal collapse which dashed expectations to the ground so abruptly and so irretrievably, could meet with no adequate explanation. Late sepsis, heart-failure, hemorrhage, indiscretion in feeding, all were suggested, but none was satisfactory to those who by long experience knew what to expect and how to recognize the nature of the complication when it came. Now that the track of the wound has been laid bare an exclamation of surprise has swept over the land. Gangrene, the result of intense devitalization of tissues or possibly of the irritating action of some unrecognized germ or virus, had destroyed the patient. The unexpected had happened. The proper course had been pursued, the dreaded complications that were common had been averted, and the medical and surgical men who had labored so loyally and conscientiously in behalf of their patient, had the satisfaction of knowing that no mistake had been made. The unusual sequel against which no precautions could have been taken, had

only revealed itself in its latent stage by rapidity of the pulse, a symptom which might have been purely functional, and one common to many conditions. We as medical men may point with satisfaction to the surgical records of the two great national patients, President Garfield and President McKinley, as an exemplification of the vast strides that have been made in the technique of surgery during the last two decades.

Affections of the Pancreas and Diabetes.—The reported wounding of the pancreas in the President's case suggests at least one physiological question which might have had a direct bearing upon his death. This question relates to the subject of accidental diabetes, and the possible effect of this condition, if it was present, on the gangrenous state of the wounds. Minkowski is authority for the statement that the complete extirpation of the pancreas in dogs invariably leads to diabetes. According to Minkowski the time which elapses after the extirpation of the pancreas and the appearance of sugar in the urine varies. Frequently after but a few hours the glycosuria is noted, and sometimes only after the elapse of three days. Hemorrhage into the pancreas in man has upon several occasions given rise to diabetes, such cases having been reported by Sarfert (*Deutsche Zeitschr. f. Chir.*, 1895, Bd. 42, S. 125) and Cutler (*Boston Med. and Surg. Jour.*, 11, 4, 1895). It is well known, as we point out elsewhere, that gangrene is not uncommonly seen in wounds and in suppurative lesions—such as boils and carbuncles—in cases of diabetes.

The Condition of the President's Heart.—In a man of the late, lamented President's age there are a number of factors to be considered by way of accounting for the heart failure, or weakness, which was a source of continued anxiety to his attending physicians. There were, it appears, no signs indicating the lesion of the pancreas or the gangrene which followed the course of the assassin's bullet.

The blood counts which were made revealed nothing, and the important index in the lack of correlation between the pulse and the temperature was not regarded seriously, owing to the fact that the President was known to have a most erratic pulse. In a man of Mr. McKinley's obese frame and full, sedentary habit, fatty degeneration of the organ was to be expected. This would naturally have followed the hypertrophy succeeding his active army life. Granting the absence of organic valvular disease, as medical men we are interested in speculating as to what might have produced the asthenic condition. In addition to the cause of the original hypertrophy present, the arduous life of the President's younger manhood, he is said to have

been an habitual user of tobacco. The effect of tobacco is to cause nervous over-action, which will in time lead to a hypertrophic condition of the heart, owing to the extra work it throws on the organ. This hypertrophy in time naturally underwent changes of fatty infiltration and degeneration, and consequently dilatation. These may be accounted for by the increased obesity of the distinguished patient and the condition of arteriosclerosis, to be expected in a man of his years and affecting to some extent the coronary arteries.

The effect of the long continued, general anesthesia is not to be overlooked. It has been shown quite conclusively that blood inspissation, a condition of anhydremia, is present after etherization. The hemoglobin is reduced absolutely and a general hemolysis of varying degrees occurs.

These conditions would throw increased work on the already weakened muscular structure, oxygenation requiring so much more effort. If we add to this the effect of the shock, and the toxemia induced by the pathological processes within the abdominal cavity, it is easy to understand how tired nature was beaten in the heroic battle and how one of God's noblemen was lost to a sorrowing people.

The Assassin.—The world once more stands aghast at the crime of an unrestrained Nihilist. The American people—impotent in their benevolence, tolerant to the last degree of any and every extreme social and political heresy that airs itself under the ægis of free speech—stand at the bier of one of their best beloved Chief Magistrates, and tacitly confess that they see no remedy under the constitution and the laws. The situation, shorn of its elements of direst tragedy, would be grim in its suggestion merely of what is helpless and maladroit.

To the mind of the sociologist—of the scientist who studies the pathology of the body politic, just as the physician studies that of the body physical—the situation does not present itself as such a paradox. If there is any standing principle in pathology it is that a disease process should be rooted out. This whole cankerous process of nihilism and anarchy is a disease—social and political infection.

Let no one misapprehend the real elements of this problem. We do not intend for a moment to raise in these columns the threshed out questions of insanity and responsibility. Fortunately and indubitably these questions ought not to be raised in this case. But there may be more than one kind of pathological process in the state. Ignorance, superstition, crime, class hatred, insanity and degeneracy—these are not interchangeable terms. However closely they may dovetail with one another (and that they are mutually reinforceful is not to be denied) they are nevertheless distinct and individual. They must

be studied apart as well as together. They must be analyzed and dissected, and the morbid state of each must be differentiated. The modern school, headed by Lombroso, which confuses criminality and insanity, has gone too far. Ignorance is more potent than either of these for harm to the State.

So long as a civilized state commits itself to the theory that any harebrained doctrines are harmless (and therefore permissible) so long as they are merely spoken, just so long will such a state be subject to the rude surprises that come when such doctrines are bodied forth in deeds. To such a rude surprise have we come now in this country, as we sit in our supreme sorrow and our profound humiliation. This assassination is the foul discharge of a local gangrene in the political body, and the moral, drawn from medical science, is obvious.

Abuses in the Pension Bureau.—There has recently been issued a stirring circular, signed by the Commissioner of Pensions and addressed to the United States Examining Surgeons. It states that carelessness and indifference in constructing certificates have compelled the recent dismissal of a number of boards; and that continuance of such conduct by others will result in dispensing with their services in the near future. The things chiefly complained of are "the use of stock phrases, the machine-made character of the descriptions of the disabilities, and the persistence in rating on the statement of the claimant or his attending physician." It states that many boards "describe organic disease of the heart as present in nearly every claimant they examine." They report "the same condition present in each case and describe it in practically the same machine-made phraseology."

It is a question whether the abuses here exposed reflect more upon the medical profession than they do on the political methods by which examining boards have been selected and kept in office. Certain it is, that the duties of the medical examiner demand both scientific enthusiasm and rigid adherence to truth. The problems presented to him are complex and often baffling. Only the enthusiast will persistently grapple with them and bring all his powers to their mastery. Only the man who enjoys overcoming difficulties of diagnosis can be trusted not to lie down and accept the suggestions of interest or habit. The profession can furnish plenty of the right kind of material, if the Commissioner will devise some improved way of selecting it.

A Valuable Surgical Procedure in Ophthalmology.—While the progress of medical science in the aggregate has for some time been deliberate and gradual, it is not rare for one of its numerous specialties occasionally to make prodigious strides. This

is exemplified in the paper which we publish in this issue on the treatment of the apparently unaffected, or at the most but slightly involved eye in cases of glaucoma, written by Dr. G. E. de Schweinitz. Operative procedures, such, as for instance, the disarticulation of a limb for malignant disease, situated at some distance from the articulation, would at one time have aroused not only much adverse criticism, but even condemnation; and to the surgeons who succeeded in taking time and life by the forelock is due the gratitude of humanity. No less a service is promised by the stimulation of discussion on the subject agitated by Dr. de Schweinitz. The bilateral tendency of the varieties of glaucoma under discussion seems clearly to indicate the practice of preventive iridectomy on the neighboring eye. In a destructive affection like glaucoma an opportune and successful preventive iridectomy on the not yet or only slightly implicated eye is of no little import. The results of extensive clinical experience have frequently revolutionized individual doctrines contained in text books, which may possibly also account for the dearth of recognition which this matter has received in treatises on ophthalmology. But will the patients submit to an operation on an eye which only expert examination can pronounce to be already affected? They will, provided we educate them as they have been in the case of other surgical procedures, notably the operation for appendicitis, which is frequently performed between attacks and in the absence of subjective disturbances. A subject like the one coming from the pen of Dr. de Schweinitz we cannot afford to ignore.

The Bribe for the Doctor.—A circular lies before us assuring the "Dear Doctor" to whom it is addressed that a certain "Institute" has "a perfect specific for all addictions." It winds up thus: "Our prices for cures: Opiates, \$100; liquors, \$60. Your compensation for each patient sent us will be 20 per cent. cash." Such circulars are more common of late. Probably the men who pay for printing and distributing them hope to get their money back and more with it. We wonder what they base their hope upon! Has the late discussion on division of fees given a fresh impetus to these efforts to make the profession a catpaw to quackery?

It is said that the great majority of efforts to make a fortune out of a patent medicine are failures. It is probable that these efforts to get the doctor to play the part of a bunco-steerer are very often as much of a disappointment and harm to their promoters as to any one else. But it is unpleasant to reflect that sometimes such schemes must get the assistance of so-called doctors, or they would not continue to bid for it.

Of course the man who is ready to sell his con-

science and self-respect for 20 per cent. of a fee generally drops quickly to a level of degeneracy, at which he can do little harm. He soon loses the confidence of the community, and with it the power to aid in schemes for swindling it. But it is a matter of regret and shame that he should ever have been counted as a member of the medical profession. We wish that this reflection could be impressed on the faculties of medical schools. Could not some young men be saved from falling into such practices and disgracing the schools that turn them into the profession by a little systematic instruction in medical ethics?

Reviews.

Diseases of the Intestines, by Dr. I. Boas, Specialist for Gastro-Intestinal Diseases in Berlin. Authorized Translations from the First German Edition, with Special Additions, by Seymour Basch, M. D., New York City. With Forty-seven Illustrations. New York. D. Appleton Company, 1901.

Some of the most difficult problems in internal medicine are presented by the diseases of the digestive system, and, more especially, of the intestinal tract. This is partly due to their physical relations, which are so intimate that the imaginary surface lines of their boundaries are of little value in topical diagnosis; but still more to the fact that the symptoms of their disorders are generally vague and often misleading. It is unnecessary to give examples of these facts, which are admitted, as soon as stated, by all experienced clinicians.

The thorough study of the diseases of one of these organs is necessarily directly helpful, but it cannot be undertaken successfully without indirectly contributing to our knowledge of them all. This is particularly true of the intestinal tract which not only underlies, but covers and interpenetrates all the abdominal viscera; a statement which applies as well to their functional as to their anatomical relations.

In the work before us, the problem, i. e., the facts, the symptoms, of diseases of the intestines, is fully and clearly stated; the proper methods of its study inculcated, and the solution—the diagnosis—logically deduced. Let it not be supposed, however, that therapeutics are neglected. About sixty pages are devoted to the general therapeutics of intestinal diseases, while the special therapeutics of each affection receives separate consideration.

The work is divided into two parts, a general and special, one of the most interesting chapters of the former being devoted to the examination of the feces. In this connection it is important to note that the *yellow mucous granules*, barely visible macroscopically, which Nothnagel regards as indicative of catarrh of the small intestines, have never been detected by Boas, and that Ad. Schmidt, who also questions their mucous structure, regards them as dead amebae.

In this chapter Boas calls attention to the fact, not generally known, that fully developed sarcinae are not infrequently found in the feces of patients suffering from gastrectasia, and states that several times his suspicions of a dilated stomach were first excited by the detection of sarcinae in the stools.

Another sign to which varying degrees of diagnostic significance is attached by different authorities, is the presence of Charcot-Leyden crystals in the feces. First associated with ancylostomiasis by Perroncito and Bäumer, they are regarded by Leichtenstern as pathognomonic of that condition, although the value of this statement is somewhat impaired by his admission of their great frequency in association with all forms of intestinal para-

sites. Boas justly remarks that Leichenstern's observations have not received the attention they deserve.

After all, however, the presence of these crystals in cases of helminthiasis is a fact of purely scientific interest, for they are much more difficult of detection in the feces than are the eggs of the parasites with which they are associated.

The chapter on the diagnostic value of urinary examinations in intestinal diseases is short but suggestive. The decision with reference to indican is that this substance in the urine is "of decisive value only when taken in connection with all other clinical symptoms."

One of the admirable features of the book is the generous recognition of the work of other clinicians and especially that of Americans. A gratifying example of this statement is to be found in the chapter on membranous enteritis where the "first classical description" of this disease is justly attributed to the late Professor J. M. DaCosta.

The chapters on round ulcer of the duodenum, as well as those on intestinal neoplasms and intestinal obstruction, though concise, are sufficiently elaborate for a work of this sort. In fact, they are excellent examples of condensed information.

To chapter XIX, which is devoted to appendicitis, the editor has appended "a brief résumé of the American views on appendicitis." This addition is most proper, for, as Dr. Basch remarks: "Whether from climatic, racial, dietetic, or other influences, the type of disease in Europe is a far milder one than in the United States, or whether, because less prevalent, its gravity is not so fully appreciated, certain it is that the medical profession abroad regard appendicitis in a far more sanguine light than we do in this country."

The work of the translator, a former assistant of Dr. Boas, is worthy of the highest praise. It shows him to be so thoroughly conversant with the structure of the German and English languages as to be able to keep the idiom of each in their proper places, i. e., at home.

It is proper to inform the would-be purchasers of this book that it does not contain a separate chapter on intestinal parasites. This, in our opinion, is scarcely to be regarded as an omission, for, as Dr. Boas remarks: "They are treated of fully in the standard text-books of medicine and in numerous monographs."

In conclusion, we heartily recommend this book to the American profession, believing that its object as stated in the preface: "To aid the practitioner in solving some of the difficult problems in intestinal pathology and assist him in the treatment of his patients," will be attained.

[F. P. H.]

Practical Surgery, A Work for the General Practitioner.

By Nicholas Senn, M. D., Ph. D., L. L. D., Professor of Surgery, Rush Medical College, Chicago. 8vo., pp.1133, 650 illustrations. Philadelphia and London. W. B. Saunders & Co., 1901.

A volume of this magnitude and character, from the pen of a great surgeon, demands more than passing notice. It must be looked at from the point of view of the practical surgeon, who opens it to learn the views of one, whose acknowledged position gives his opinions unusual weight, and from that of the general practitioner for whom it is said to have been written.

The trained surgeon will open it eagerly and find its contents of extreme interest and great value. He will read with zest the arguments on mooted points, add to his knowledge by absorbing some of the learning of Dr. Senn, revise his own views by comparing them with the opinions of a teacher of wide experience, and close the volume with a feeling of astonishment at the great amount of original work done by the author.

The general practitioner, however, will scarcely find it of the value he expected. In a technical work of reference, arrangement and method are almost as important as matter. In these essentials the present work is deficient. It lays too much stress on some subjects, says too little, or nothing, about others; and gives up too many pages to historical accounts, details of experimental work and original investigations, to be a convenient and practical guide to the man who fills the honorable and anxious post of general practitioner.

The book is full of the author's personality and many of its statements deserve quotation, because of their in-

trinsic value, and because they illustrate the nature of its teachings. "The life of every anesthetized patient is always in danger." "Very few physicians are safe anesthetizers." "No matter how competent the anesthetizer may be, the surgeon should never lose sight of his patient, no matter how trying the operation."

"Asepsis is the precious, hard-earned reward for faithful antiseptic labor." A wound from a modern bullet "should never be probed, either for diagnostic or therapeutic purposes." "Dirty hands have destroyed more lives than all the implements of warfare." "As an unmistakable indication of fracture, a new point of motion is of greater diagnostic significance than preternatural motion." "The search for crepitation (in fractures) should never be made unnecessarily, as in many instances this sign is absent, and in the vast majority of cases a satisfactory diagnosis can be made by a careful study and analysis of the other symptoms."

"In all dislocations the untorn portion of the capsule or ligaments plays an important rôle in fixing the displaced bone in its abnormal position and in resisting efforts at reduction."

In speaking of cellulito-cutaneous flaps in amputation, he says: "I am strongly impressed with the importance of including in the flap the deep connective tissue, **** as by doing so an important hold on the cut muscles is secured."

In science it is not unusual to criticize even the work of a master, and criticism is proper, when necessity arises; but the criticism should have at its root the wish for better results from so high a source. The author is a standard by which an author's work is judged, and a great man must not fall below his best. It is this feeling, which causes regret that the volume under review has not the system, conciseness, and directness, which have made the value of many books of less distinguished men. [J. B. R.]

Staining of Ameba.—E. S. London, in a paper entitled "Histologic Notes" (*Archiv. Biologischeschik Nauk*, Vol. VIII, No. 3) points out that in the examination of fresh unstained specimens for ameba leukocytes may be encountered which are indistinguishable from the ameba. For this reason the latter are detected with more certainty in stained specimens. The method of staining is as follows: The suspected mass is spread in a thick layer on a cover glass or slide, and dried in the air until it assumes the consistency of dough. The preparation is then treated with a saturated solution of bichloride of mercury for 5-10 minutes, washed several times with 95% alcohol and finally with distilled water. If the film shows a tendency to wash off the water may be omitted and the alcohol allowed to evaporate. The film is stained for 2 to 3 minutes with a stain containing rose bengale, 0.1 grm., aniline yellow, 0.15 grm., 95% alcohol 30 c.c. and distilled water, 70 c.c. It is then washed with distilled water until the washings are no longer colored and counterstained by Loeffler's methylene blue for 1 to 2 minutes, the excess of stain being removed by 95% alcohol followed by absolute alcohol. The preparation is then mounted in balsam. The following microscopical appearance is presented: The protoplasm of the leukocytes is stained red and the nuclei blue, while in the case of ameba the reverse is seen, the protoplasm is blue and the nuclei red. These observations were made on ameba nitrophila. [A. R.]

Alquist-Alexander-Adams Operation for Retroversion and Prolapsus of the Uterus.—A. Eberlin (*Medicinskoie Obozrenie*, June, 1901) gives the following conclusions based on observation of 24 cases: 1. Of all the operations recommended for the treatment of retroversion and prolapsus the shortening of the round ligaments in the inguinal canal is the most rational, the least dangerous and the more satisfactory as to a permanent cure. 2. With good technique, the operation is always successful. 3. The best way of finding the ligament is to open the inguinal canal. 4. The operation is free from complications and does not interfere with pregnancy or labor; while the latter do not weaken the effect of the operation. 5. After rational and careful closure of the wound there is no danger of hernia. 6. The careful isolation of the round ligaments at the internal ring plays the primary rôle in securing good results and preventing hernia. 6. It is desirable that authors report their observations on the remote effects of this operation. [A. R.]

American News and Notes.

The Death of President McKinley.—After an operation which was perfect in the surgical aspect, the lack of development of symptoms of sepsis and peritonitis, and the lapse of almost a week, in which all the indications pointed to a speedy recovery, the sudden change for the worse in the President's condition, altogether unlooked for, came as a shock to the whole country. Hourly bulletins, issued direct from the sick chamber and signed by the physicians in charge, were very encouraging. Feeding by the mouth was begun on Tuesday morning, and was well borne, and since Wednesday all nourishment had been administered in this way. Thursday night, however, brought a decided change for the worse. On Friday he rallied slightly, but Friday evening his condition grew gradually worse, until 2.15 A. M. Saturday, when he died. The autopsy was held on Saturday morning at 11 o'clock. It was performed by Drs. Gaylord and Matzinger, in the presence of all the physicians who had attended the President during his illness. The report was awaited with great interest, and when it appeared it occasioned much surprise. It showed the President's death to be due to gangrene. The whole course of the bullet's track was gangrenous. The bullet perforated both walls of the cardiac portion of the stomach, and lacerated the upper portion of the left kidney. The physicians, though they did not find the bullet at the autopsy, are confident it is imbedded in the muscles of the back. Both wounds in the stomach were found to be perfectly closed, but around each wound was a gangrenous area the size of a silver dollar. The upper portion of the left kidney, part of the spleen and pancreas were also found to be gangrenous. The heart walls proved to be thin, but otherwise were normal. There was no sign of peritonitis or disease of other organs. This closes all criticism as to the methods of treatment employed by the President's physicians and surgeons, death being unavoidable by any medical or surgical treatment. Dr. Mynter is of the opinion that the ball was poisoned, and a bacteriological examination is to be made of the remaining bullets in the chamber of Czolgosz's revolver, a report of which will be awaited with much interest, as will also a further report of the autopsy.

A Brief Personnel of the Surgeons in Attendance Upon President McKinley.—Dr. Matthew Mann, known as an eminent abdominal surgeon, is 56 years of age, and has practiced in Buffalo for about thirty years. He is the author of a standard text-book on gynecology, professor of gynecology at the University of Buffalo, and gynecologist in the Buffalo General Hospital.

Dr. Roswell Park is a graduate of Rush Medical College, and is about 48 years of age. He is the author of Park's "System of Surgery," and is well known to the profession the world over. He is surgeon-in-chief to the Buffalo General Hospital and professor of surgery at the University of Buffalo.

Dr. Herman Mynter is an expert abdominal surgeon, and author of a valuable work on appendicitis. He has recently lectured abroad on this subject. He is now surgeon to the German Deaconess Home at the German Hospital.

Dr. John Parmenter is about 40 years of age. He is professor of anatomy at the University of Buffalo, and is a careful operator.

Dr. Eugene Wasdin is about 40 years of age. He is surgeon to the Marine Hospital. He was one of the experts recently detailed to investigate yellow fever in Cuba.

Dr. T. W. Lee, of St. Louis, was medical director of the Omaha Exposition.

Dr. N. W. Wilson is post surgeon at Fort Porter. He is the sanitary officer of the Pan-American Exposition.

Dr. P. M. Rixey is a medical inspector in the United States Navy. He served as assistant surgeon in the navy for a number of years. Dr. Rixey was chosen physician to the McKinley family three years ago upon the removal from Washington of General Leonard Wood, who had been the family physician.

Charged with Spreading Smallpox.—A suit for \$10,000 damages has been brought by Elmer C. Meyers and his wife against John Crum, a farmer near Linglestown, Pa., based on the allegation that Crum took a smallpox patient to the home of Mr. Meyers, and in consequence infected the entire Meyers' family.

PHILADELPHIA, PENNSYLVANIA, ETC.

Philadelphia County Medical Society.—The first regular meeting of this society after the summer intermission was held September 11, President George Erety Shoemaker occupying the chair.

The scientific business included two papers. The first was read by Dr. Emma E. Musson, on *Rarefying Ostitis in Chronic Purulent Ethmoiditis Simulating Atrophic Rhinitis*. After considering the opinions of various authorities, Dr. Musson stated that clinical experience had convinced her that the following two conditions are separate and distinct diseases, viz: (1) chronic empyema of the accessory sinuses leading to rarefying ostitis and (2) atrophic rhinitis. Prognosis differs greatly in the two conditions, being favorable in the former and decidedly unfavorable in the latter. Four illustrative cases were briefly detailed by Dr. Musson. Some of them had been diagnosed and treated as atrophic rhinitis, one at least having the four typical symptoms of that disease. Cure (or in cases now being treated, improvement) followed curettement and treatment of the ethmoidal cells which were found to contain pus and necrosed bone. Differential diagnosis between the two affections is difficult. The involvement in atrophic rhinitis is usually more extensive, the sense of smell is more often lost, probing finds no carious bone, and the disease does not tolerate surgical treatment. In suppuration of the ethmoidal or other sinuses probing reveals carious bone, the sense of smell is more often retained, and plugging of the nasal cavity will show the presence of pus on the surface of the plug which borders the cells.

Dr. Boardman Reed read a paper on *The Etiology and Symptomatology of Constipation, including the Differential Diagnosis between Atonic and Spasmodic Constipation*.

Dr. Reed spoke of the various causes of constipation and stated that the most prolific causes were atony and spasm. These two forms are also the most amenable to treatment other than surgical procedures. Constipation due to spasm is the most often seen in hysterical and neurasthenic individuals. Massage of the intestines is not indicated in this form, unless it be in the shape of light stroking in some cases. General roborant treatment, diet, and special exercises are indicated. The differential diagnosis between the two varieties is of great importance in determining the treatment. In the atonic form the stool is too small in amount, there is little straining during the movement and the patient feels relieved as after a thorough passage. The condition is more constant and there is no rigidity of the muscles. Percussion often reveals general tympany. In the spastic variety the condition is never constant. The stools will be normal at times or there will be diarrhea. Movements cause great straining and there is no feeling of relief afterward. Tender spots in the abdomen are apt to occur. Occasionally both forms may be found in the same individual.

Dr. William McKinley Dead.—Dr. William McKinley, a distant relative of the late President McKinley, and a graduate of the Baltimore Medical College, was found dead at his home at Polk, Pa., on the night of Sept. 14th. He was 44 years old. On that day Dr. McKinley was in Franklin, Pa., and discussed the death of the late President with friends there. He was of a highly nervous disposition, and at different times during these discussions he became greatly excited over the assassination. In the evening he returned to Polk, and a few hours after his arrival there his dead body was found lying on the ground in the rear of his residence. Death is said to have been due to apoplexy.

Vital Statistics for Philadelphia for the week ending September 14, 1901:

Total mortality	430	Cases.	Death.
Inflammation of the appendix 3,			
bladder 1, brain 9, bronchi 5, kid-			
neys 16, larynx 1, liver 2, lungs			
26, pericardium 1, peritoneum 6,			
pleura 1, stomach and bowels 31,			
spleen 1			103
Marasmus 29, inanition 20, debility			
6			55
Tuberculosis of the lungs			47

	Cases.	Deaths
Apoplexy 16, paralysis 11		27
Heart-disease of 27, neuralgia of 4 ..		31
Uremia 10, Bright's disease 7, diabetes 2		19
Carcinoma of the face 1, breast 3, stomach 3, uterus 6, liver 1		14
Convulsions		13
Diphtheria	51	4
Brain-disease of 1, softening of 2 ..		3
Typhoid fever	97	11
Old age		10
Scarlet fever	24	1
Abscess of lungs 2, atheroma 1, asthma 2, burns and scalds 4, casualties 12, child birth 1, cholera infantum 14, cholera morbus 1, cirrhosis of the liver 4, croup, membranous 2, cyanosis 1, diarrhoea 2, drowned 3, dysentery 2, erysipelas 1, fever, remittent 1, hemorrhage from stomach 1, homicide 2, jaundice 1, leukemia 1, locomotor ataxia 1, obstruction of the bowels 3, rheumatism 1, sclerosis, liver 2, shock, surgical 1, septicemia 6, smallpox 4, sarcoma 1, suffocation 1, suicide 8, unknown coroner case 1, whooping cough 4		91

NEW YORK.

Hospital Superintendents Confer.—The third annual conference of the National Association of Hospital Superintendents was held in New York, September 10 and 11, with a good attendance of delegates. An invitation to hold the next annual conference in Philadelphia was accepted by a unanimous vote.

Medical Association of Central New York.—Among the most important medical societies in the East is the Medical Association of Central New York. This society was organized by the generation now almost passed away, and has had an interesting and active life for more than a third of a century. Its meetings are held annually, rotating between Syracuse, Rochester and Buffalo, usually in October. This year's meeting was held in the latter city a little earlier (August 27 and 28) to accommodate itself to Pan-American arrangements. Dr. Lucien Howe, of Buffalo, presided, and the literary program was unusually attractive. The usual banquet was held in the "Streets of Mexico," at the Exposition. The after-dinner speeches were made by Dr. William B. Jones, of Rochester; Dr. Floyd S. Crego, of Buffalo; Dr. John L. Heffron, of Syracuse; Dr. Eugene Wasdin, of the United States Army, and various other representative men. The next meeting will be held at the usual time at Syracuse.

NEW ENGLAND.

New England Hospital for Women and Children.—Henry A. Turner, who died recently in Boston, bequeathed \$10,000 to the New England Hospital for Women and Children in that city as a memorial to his two daughters.

New Hospital for Tuberculosis.—A new hospital for tuberculosis is being erected in a suburban section of Hartford, Conn., at a cost of \$50,000, half of which has been donated by the State.

WESTERN STATES.

New Hospital for San Francisco.—San Francisco is to have a new hospital. It is to be erected by the German General Benevolent Society of that city, at a cost of \$250,000.

Banquet in Honor of Nathan Smith Davis, M. D., L. L. D.—Under the auspices of the Chicago Medical Society a banquet and celebration will be given in honor of Nathan Smith Davis, M. D., L. L. D., who is the oldest living presi-

dent of the society, and widely known and honored among the profession through his long connection with the American Medical and other associations. The banquet will take place at the Auditorium Hotel Chicago, Saturday evening, October 5, 1901.

Dr. Stewart L. McCurdy, formerly professor of orthopedic surgery, Ohio Medical University; at present professor of anatomy and surgery in the dental department of the Western University, has been elected to the chair of orthopedic surgery in the Western Pennsylvania Medical College, Pittsburg.

Dr. H. G. Nicks, physician to the Christian Orphans' Home, has been elected clinical professor of diseases of children in the St. Louis College of Physicians and Surgeons.

Chicago Hospital School for Nervous, Delicate and Invalid Children.—The Board of Trustees of the Chicago Hospital School for Nervous, Delicate and Invalid Children, has added to the school curriculum a special department for the correction of speech defects. The school will open Tuesday, October 1st, 1901. After this date, in addition to the present course of study, the school will be prepared to furnish instruction either by classes at the hospital-school or private instruction by the hour, in the correction of speech defects and speech inaccuracies. This phase of work will cover cases of stammering, major and minor inaccuracies—enunciation, pronunciation, cases of retarded speech development, and lip-reading whereby those having lost hearing may be taught to read lips of others. Instruction will also be given to young deaf children, and children of slightly imperfect hearing. For this department they have provided four teachers: Miss Gwendolyn Williams for voice development and voice placing, stammering and stuttering, she has studied under William Shakespeare, of London, Prof. William Tomlins, of Chicago, and at the Curry School of Expression, Boston, Mass. She has taken special work in correction of speech defect under Mrs. Monroe, member of the faculty of the Fuller School for the Deaf and of the faculty of the Curry School of Expression, Boston, Mass. Miss Laura Robie, for non-development of speech, lip reading for adults and juveniles, and for instruction of young deaf, or partially deaf children. Miss Robie is a graduate of the Wisconsin Phonological Training School for Teachers, 1899-1900, and was head of the Educational Department for Deaf Children at Muskegon, Mich., 1900-1901. Miss Catherine Dewey for music—vocal and instrumental, voice development and musical phonetics, has studied under Prof. William Tomlins, of Chicago, and Mrs. Kern, in charge of the Department of Music at the John Dewey School and of the Chicago Institute of the University of Chicago. Miss Margaret McKee will continue in charge of a special case in the school—a congenital-partly-deaf child. Miss McKee is head teacher of the Department for Deaf Children in the Kosminski School.

New Hospital for Fort Smith, Ark.—A new hospital is to be erected at Fort Smith, Ark., at a cost of \$10,000.

Appointment.—Dr. L. Blake Baldwin has been appointed professor of clinical dermatology at the College of Physicians and Surgeons of Chicago.

A Chinese Leper.—A Chinese Leper has been unearthed at St. Louis. The patient is Dong Goud, whose vanity caused him to seek relief for an eruption of the face. The examination led to his being suspected, and upon a further examination by dermatologists, he was declared to be affected with macular leprosy of the anesthetic type. He will be isolated.

Southern Minnesota Medical Association.—The tenth annual convention of the Southern Minnesota Medical Association was recently held at Rochester, Minn. A number of interesting papers were read.

CANADA.

(From Our Special Correspondent.)

Deaths from Consumption in Ontario are beginning to wane, and it is hoped by the Provincial Health Officer that the fight against the plague is beginning to tell in the monthly vital statistics. One hundred and eighty-two deaths occurred in the province during July of the present

year, municipalities containing 91 per cent. of the population registering. Compare this number with 264 deaths from the same cause in July of 1900, when municipalities containing 97 per cent. of the population reported. Thus it would seem that a small, but steady, improvement was being made, which may be set down to improvements in isolation and regulations controlling the disposal of expectoration.

Theories re Tuberculosis have recently been discussed by Prof. J. George Adami, of McGill University, who attended the Tuberculosis Conference at London. He believes that too great emphasis has been placed in the past on the danger to be apprehended in milk, from tuberculosis in cattle; but he does not believe it is right to state there is no danger. Two years ago, when the Canadian Medical Association met in Toronto, Dr. Adami contributed an able paper on this very subject, and, therefore, Koch's theory is not an entirely new one to the profession here. The paper, which he then read, along with other documents, was sent to Berlin and came into the hands of Dr. Koch, who in this manner became conversant with the work then being done in Canada in this connection. For the last two years Prof. Adami, Dr. C. F. Martin and Dr. Higgins, of Montreal, have been working along these very same lines, and the Canadian Government was fully aware of the trend of the work. Dr. Adami's paper referred to was entitled "Is Bovine Tuberculosis Infectious from Animal to Man?"

The Ontario Medical Council and the Medical Defence Association are not much in love with each other, and the latter promises to have it out to the full. This Medical Defence Association must not be confounded with any organization looking towards protecting practitioners from suits for alleged criminal malpractice, as it is nothing of the kind, its object being primarily and all the time to correct evils which they claim exist in the composition and laws of the governing body of the College of Physicians and Surgeons of Ontario—the Medical Council. The Executive Committee of this organization recently held a meeting in Toronto and decided that the grievances against the Medical Council should be properly brought before the profession in Ontario and the public generally, with the object of influencing the Legislature in their behalf at the coming session. Dr. J. H. Sangster, the Secretary of the Committee, was urgently and unanimously requested to undertake the compilation and presentation of a series of letters to the public press, and in his first letter declares there are three formidable, but not insuperable, obstacles to success in this matter, viz: The absence of public interest and sympathy, the almost Asiatic apathy of a large section of the profession itself and the determined resistance of the medical schools, that were suffered to shape the Medical Act of 1869, by which they engineered themselves and a comparatively large contingent of homeopaths into the executive of the profession. It will be interesting to report further on what sort of a case Dr. Sangster will be able to make out against the constituted authority of the profession in Ontario.

The College of Physicians and Surgeons of Quebec, like its contemporary in Ontario, too, is having troubles of its own, but in a somewhat different way. Dr. H. C. Dumont, who has been refused a license in that Province, although he claims to have passed all the examinations and had studied medicine during the number of prescribed years, only a few days ago was granted a petition by Mr. Justice Langle for a writ of mandamus. On the part of the College, it has been urged that Mr. Dumont had not conformed with the regulations governing the admission to study prescribed by the College of Physicians and Surgeons; hence their refusal to license. The mandamus orders the College to issue the license. Last year five or six cases were decided similarly against the College, and the present one will now be considered as a test case. The College will take the case through the court of appeal and to higher courts, if it be found necessary.

The British Columbia Medical Association held its second annual meeting at Victoria on the 5th and 6th days of September, when a full representation from the Province was present, and several practitioners from the East, who had been attending the Canadian Medical Association at Winnipeg, came on after the close of that meeting. Dr. Dune presided, while Dr. J. M. Pearson, of Vancouver, acted as secretary. A special steamer took the delegates to the William Head Quarantine Station, and to a visit to the

lepers confined on Darcy Island. The annual banquet was held at the Driad. Several interesting and valuable papers were read, including one by Dr. R. E. McKechnie, of Nanaimo, on "Midwifery" and one by Dr. Fagan on the subject of "Tuberculosis." The following officers were elected for the ensuing year: President, Dr. Walker, of New Westminster; vice-president, Dr. McEugan, Vancouver; treasurer, Dr. Helmchen; secretary, Dr. J. M. Pearson, Vancouver.

Two Dowieites have been arrested at Victoria, B. C., one an elder and the other a disciple. They are charged with manslaughter for refusing to provide proper medical assistance for the infant child of the latter.

The Medical Staff of the Montreal General Hospital for the ensuing year will be composed of Dr. von Eberts as medical superintendent and the following as house surgeons: Drs. Turner, Secord, Robertson, Campbell Howard, Bruce, Brown, Rogers and Ker.

Dr. Montizambert, Director-General of Public Health at Ottawa, has handed in his report to the Dominion Government on the recent Tuberculosis Conference held at London, to which he was a delegate. It is understood he combats Professor Koch's theory regarding the transmissibility of bovine tuberculosis to human beings.

Dr. Laberge, Medical Health Officer of the city of Montreal, has gone to Germany to attend a medical conference shortly to be held in that country.

Hospital for Contagious Diseases.—A hospital for contagious diseases is to be erected in Ottawa, Canada, at a cost of nearly \$20,000.

MISCELLANY.

Obituary.—Dr. Louis Warfield Ritchie, at Georgetown, D. C., September 10, 1901, aged 48 years—Dr. William McKinley, at Polk, Pa., September 14, 1901, aged 44 years.

Poisoning From Tin Chloride in Stockings.—An interesting case is reported in the *Wiener klin. Rundschau* of this kind of poisoning, and quoted in the *Oklahoma Medical News*. A young lady, who had been wearing yellow silk stockings, noticed a sudden disturbance in motility and sensibility in her limbs. Several weeks later more intense symptoms, simulating ataxia, set in again after wearing the stockings. On examination these were found to be impregnated with tin chloride. The urine contained albumoses, serum albumen and globulin, and gave the tin reaction for months after she ceased wearing the stockings. There was also some destruction of the corpuscular elements. Silk, especially the light shades, should not be worn next to the skin, as it is oftentimes considerably impregnated with tin chloride to increase the body of the silk. The patient in this case recovered, although hysterical symptoms persisted for a long time.

Olive Oil.—Seventy-five per cent. of the "olive oil" in our markets, says Schlichting, consists of mixtures of cottonseed and other oils (peanut, palm, etc.). Most of the "pure imported Lucca oil" comes from the cotton fields of Georgia, whence it is sent in bulk to Europe, and there used to adulterate the olive oil.

Segregation of Lepers in the Philippines.—The United States War Department has received the report of a Board of Officers, appointed not long ago to recommend a suitable island of the Batanes Islands for the segregation of lepers. The Board recommended the island of Barri. Its water supply is good, soil fertile, and timber is good. The report states, however, that at certain seasons of the year the group of islands to which it belongs is swept by typhoons.

Changes in the Medical Corps of the Navy, Week Ended September 14, 1901.

MEDICAL INSPECTOR H. WELLS, ordered to the Boston Navy Yard, September 14—Sept. 7.

MEDICAL INSPECTOR W. E. TAYLOR, retired, ordered to the Honolulu Naval Station—Sept. 7.

MEDICAL INSPECTOR R. C. PERSONS, ordered to duty at the marine recruiting rendezvous, New York, N. Y., September 9, and to other special duty—Sept. 7.

SURGEON M. H. CRAWFORD, detached from duty at the marine recruiting rendezvous, New York, N. Y., September 9, and ordered to duty in connection with fitting out the Illinois and to duty on that vessel when put in commission. Sept. 7.

PASSED ASSISTANT SURGEON D. N. CARPENTER, detached from the Naval Hospital, Norfolk, Va., and ordered to duty in connection with fitting out the Illinois, and to duty on that vessel when put in commission Sept. 7.

PASSED ASSISTANT SURGEON G. D. COSTIGAN, resignation accepted, to take effect September 16—Sept. 9.

PHARMACIST J. COWAN, detached from the Naval Hospital, Mare Island, Cal., ordered home and granted sick leave for one month—Sept. 9.

PASSED ASSISTANT SURGEON C. E. HIGGS, detached from the New York Navy Yard and ordered to the Port Royal Naval Station—Sept. 11.

ASSISTANT SURGEON J. C. THOMPSON, detached from the Port Royal Naval Station and ordered to the Columbian—Sept. 11.

ASSISTANT SURGEON R. M. YOUNG, detached from the Naval Hospital, New York, September 14, and ordered to the New York Navy Yard, same day—Sept. 11.

ASSISTANT SURGEON A. G. GRUNWELL, detached from the Brooklyn and ordered home—Sept. 12.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ended September 14, 1901.

GREAT BRITAIN.

A Chair on Anesthesia.—The reorganized University of London has arranged for a corps of teachers for instructing in anesthesia.

Death of Alfred E. A. Lawrence.—We regret to learn that Dr. Alfred E. A. Lawrence, professor of midwifery and diseases of women in University College, Bristol, died suddenly on the 30th ult. while on holiday with his family.

Honored by the University of Glasgow.—The University

of Glasgow at its recent four hundred and fiftieth anniversary conferred honorary degrees on Quincke, Mikulicz and Kronecker, of Germany.

Mr. Trevor N. Smith, J. P., F. R. C. S. I., has been appointed Assistant Master of the Coombe Hospital, Dublin.

Dr. R. Tanner Hewlett has been appointed professor of general pathology and bacteriology at King's College, London.

CONTINENTAL EUROPE.

The Eightieth Anniversary of Prof. Virchow's Birthday.—On October 13th Professor Virchow, the renowned German pathologist, will have tendered to him by his confrères a celebration which promises to rival many that have yet taken place. A detailed description of this event will be published in due time in these columns.

New Clinics in Odessa.—The city appropriated 500,000 roubles (\$250,000) for the establishment of new clinics in connection with the University.

The Regulation of Admission of Foreign Physicians to Practice in Russia.—The Department of Public Instruction is framing a law compelling foreign physicians who desire to practice in Russia to pass the regular medical examination only in the Russian language and present a certificate of preliminary education equivalent to the Russian Gymnasium.

A Twentieth Century Drug Store.—In St. Petersburg a woman-pharmacist opened a drug store, in which all the employees, except one, are women. This establishment will also serve as a school of pharmacy for women.

A Self-sacrificing Nurse.—In the Government of Vitebsk, Russia, a ten-year-old boy received severe burns, necessitating skin grafting to save his life. One of the nurses, a Sister of Mercy, offered to supply the necessary skin, and refused to take an anesthetic during the operation. She was presented with a medal.

Leprosy in Russia.—Several cases of leprosy developed in the Government of Lifland. Two cases appeared in the Government of Smolensk.

Homeopathy in Russia.—There are about 100 homeopaths, 20 dispensaries, 1 hospital and 30 drug stores in the entire country. The homeopaths are preparing to gather for the first time in St. Petersburg. The chief objects of the meeting will be the discussion of infinitesimals, as well as means of bringing the two schools together.

Legislation Against Pellagra in Italy.—An influential group of Italian Senators is promoting legislation for the prevention of pellagra, which is becoming more and more prevalent. According to the last official statistics there are about 60,000 sufferers from the disease in Italy, only 3000 of whom are in public institutions. The drying, preservation, and consumption of maize and its derivatives are to be supervised by the local authorities. The notification of every case of pellagra is made compulsory.

Dr. Juergens, for many years assistant of Virchow, and curator of the Pathological Institute, has been appointed professor.

Professor Dr. Steinbruegge, aged 70 years, died at Glessen, Germany.

Dr. Bide, of Cherment, has been appointed professor of pathology and operative medicine at the college of the same city.

Dr. Laurent has been appointed professor of pharmacy at the Rennes Medical School, replacing Dr. Lenormant, who has become professor of medical chemistry.

Dr. Bataille has been appointed professor of anatomy at the Poitiers Medical School.

Post-Graduate School of Medicine in Paris.—An effort is being made to form a Post-Graduate School of Medicine in Paris. A report has been made by the Paris Municipal Council, which favors the foundation of this Municipal Institute of Applied Medicine, for graduated physicians only. A special hospital will eventually be built for the use of the physicians, with dispensaries for all the specialties.

A League Against Syphilis.—As an outcome of the Congress on the Prophylaxis of Syphilis held in Brussels in 1899, a league against syphilis has recently been founded in Paris. The president is Professor Fournier; the vice-presidents are Drs. Béranger, Brissaud, and le Pileur. Dr. Barthélemy is secretary-general.

FERDINAND HUEPPE.

2.—Sanders reports the following case: A private soldier received a bullet wound of the head about 2½ inches above the external occipital protuberance and 1½ inches to the right of the median line. He immediately became blind and subsequently had fever. Ten days later he was operated upon and 4 drams of pus evacuated from the brain just beneath the bullet aperture. The portions of the brain involved were the anterior part of the occipital cortex on its outer aspect, the hindmost portion of the angular gyrus, and part of the white substance of the occipital lobe including part of the optic radiation. The point of chief interest is the cause for the extensive impairment of vision in both fields by an apparently unilateral lesion. This case tends to show that in man both sides of both retinæ are represented to some extent on one side of the brain. The author says the case may be described as one of left hemianopia due to injury to the occipital lobe with concentric contraction of the fields of vision on the same side as the lesion, due to the destruction of fibres of the optic below the angular gyrus. There was no mind blindness.

[F. T. S.]

4.—Keetley believes carcinoma is caused by a living organism which flourishes in either the secretions or the cells of the skin glands, e. g., milk, butter, cheese, sebaceous material and sweat, and that before milk, butter and cheese are used they should be sterilized by heat, while the secretions of the glands of the skin should be kept away by washing. The commonest seats of primary carcinomata are in the alimentary canal, where food may lodge or adhere. He says that primary cancerous infection in places which are not accessible to milk and its products may be due to conveyed infection via the lymphatics. The secondary carcinoma implies that not only the cancer germ, but the epithelium in which it lives have been conveyed from one part of the body to another. He speaks of the importance of removing chronic inflammations, suppurations and ulcerations; of avoiding well-known sources of irritation of skin or mucous membrane. He says nothing but smooth, clean linen, cotton or silk, and soap and water should come in contact with the nipples. They must not be touched with the hand or fingers. [F. T. S.]

3.—White and Hay discuss the recent inquiries and re-

searches into the poisonous properties of naphthalene and aromatic compounds. This article deals with the dosage and the relative poisonous action of naphthalene and of the aromatic series of compounds. Nitrid aromatic compounds, act as powerful poisons and influence the higher centers. In small doses they act upon the sympathetic nerves, their influence upon the blood is of a hemolytic character, and degeneration takes place in the tissues of certain organs. They found that dinitro-benzene naphthalene was more poisonous than the mono-nitro preparation. Mono-nitro-benzene did not seem to have a poisonous effect upon cats, while dinitro-benzene was found exceedingly poisonous to both animals and men. Tri-nitro benzene was slightly more poisonous than dinitro-benzene. Mono-nitro toluene did not affect cats. They did not experiment with nitro-toluene, as the compound was too dangerous to work with. Tri-nitro toluene was found comparatively harmless. By series of experiments, these authors were able to demonstrate that dinitro-benzene, when in close contact with the skin, is absorbed. [F. J. K.]

5.—Bowes reports a case of spontaneous gangrene in an infant. The infant at birth, on March 25, 1901, appeared in perfect health. On April 7th, a vesicle was noticed in center of the back in the lumbar region; this soon developed into a pustule which was surrounded by a dusky red area. The pustule ruptured, leaving a small circular ulcer, which continued to spread upwards. A red discoloration appeared in the neighborhood of the umbilicus; some of the finger tips also showed discolored patches. On April 13th, the discolored area on the back was three inches in diameter. It still continued to spread upwards and downwards. The skin appeared dusky and lifeless. Death occurred on the 14th. A post-mortem examination was not made. [F. J. K.]

6.—Nicol writes on hospital sanitation in South Africa. This article points out very clearly that the hospital alms, in certain instances, might have been more carefully selected, and also that a more careful supervision of the details of the sanitary work would have resulted in a lessening of the sickness among the hospital staff. The continued use of one particular hospital was not considered disadvantageous by the authorities, but undoubtedly fouling of the ground continually occurred when a large number of typhoid fever cases were brought together for a long time. The advantages of the canvas hospital are stated. The most important one is its mobility. [F. J. K.]

7.—Gamgee discusses the behavior of oxy-hemoglobin, carbonic-oxide-hemoglobin, methemoglobin, and certain other derivatives in the magnetic field. This author first discusses the observations made by Faraday in 1845, who concluded that the blood, notwithstanding the iron which it contains, is a diamagnetic liquid. Reference is also made to Plucker's study on the diamagnetic properties of blood. This investigator demonstrated that the blood corpuscles are more strongly diamagnetic than the plasma in which they float. The object of Gamgee's present investigation was to determine the magnetic properties of crystalline blood coloring matter. In his researches, he employed the electro-magnet constructed by Ladd many years ago, and which was found to be sufficiently powerful. He suspended between the poles of the magnet, by means of a few fibres of silk, a cake of the crystalline bodies of oxy-hemoglobin, CO-hemoglobin, and methemoglobin. He reached the following conclusions: 1. Oxy-hemoglobin, CO hemoglobin, and methemoglobin, are decidedly diamagnetic bodies. 2. Iron-containing derivatives, hematin and acethemin, possess powerful magnetic properties. The decomposition when the hemoglobin is reduced in the presence of oxygen, probably induces the change in magnetic behavior of the blood coloring matter, and the hematin and acethemin. From a preliminary study of the electrolysis of the oxy-hemoglobin and CO-hemoglobin, he found that the iron-containing group of the coloring matter was the electro-negative radical. [F. J. K.]

8.—Wingrave discusses tonsillotomy rash. He found that in his experience, both in the hospital and private practice, a rash often follows tonsillotomy, which is not necessarily specific. He noticed this rash in 34 cases, in the course of seven years. Generally, the rash makes its appearance on the second or third day. It is either papular, roseolar or erythematous in character. It may be situated upon the neck, the chest, the abdomen, the face, and the extremities. Generally, its duration is from two to three days, rarely as long as five. In the 34 cases are in-

cluded three which proved to be scarlet fever, one diphtheria, and the remaining cases were of the non-specific character. [F. J. K.]

MEDICAL RECORD.

September 14, 1901.

1. The Origin and Formation of Fibroid Tumors of the Uterus. MARY A. DIXON JONES.
2. Some Observations on Cardiotherapy. HOMER WAKEFIELD.
3. The Function of the Tonsils, etc. R. C. MATHENY.
4. A Unique Specimen of Vesical Calculi. F. C. LARIMORE.

1.—Jones, in speaking of the origin of fibroid tumors, says that medullary tissue or protoplasm contains the life-elements, and only from these life-elements can come any new formation. This is nature's law. In this way fibroid growths of the uterus are formed, and it is the only way that they or any abnormal growth can be developed. One tissue cannot produce another, nor can one structure give birth to another anatomical formation. When there is a myofibroma not only the uterus is diseased, but it is this disease of the uterus that produces the fibroid growths. Fibroid growths are diseased products and the outcome of diseased conditions. The tissues of the uterus are first reduced to granular or medullary tissue, and from this granular or medullary tissue fibroid tumors are developed. A new growth can only come by some tissue being reduced to its primal elements or to protoplasm. If any part of the uterus is seriously diseased, other portions are in a similar state. The fibroid growth does not depend upon the year, age or period of life; it is when there is infection and consequent inflammation that the growth develops. When the tumor appears it is no indication of the time of life, but it reveals the important fact that there is disease. There is a still more advanced transformation, a more thoroughly diseased uterus, the inflammation going on to ulceration. We may call them fibroid growths, myoma, fibromyoma, or what not; they are diseased products, changing formations, abnormal and uncertain growths, and continually giving new manifestations of disease. [W. A. N. D.]

2.—Homer Wakefield presents some observations on modern cardio-therapy. He details the essential action of the Nauheim bath treatment and the method of mountain climbing first suggested by Stokes and put in practice by Oertel. Speaking of the physiological action of the Schott treatment, while acknowledging the pressure of the abdomen by reflex action of the splanchnics proves a valuable means of resuscitation in collapse, especially when visceral venous stasis is marked, he does not believe that the essential beneficial results of the treatment are due to percussion. He mentions the fact that the physiological method of blood-letting as practiced by the old-time physicians in one respect accomplished the same end as the Schott method, in that it lowered the arterial pressure in reducing the total quantity of blood in the body. He mentions one of the incidental results of the Nauheim bath, the fact that the patients often have an attack of acute or subacute rheumatism after taking their initial baths, and mentions that this may possibly be due to the rapid production of peripheral hyperemia. A valuable bibliography of reference is appended to this article. [T. L. C.]

3.—R. C. Matheny discusses the function of the tonsils, with a few suggestions regarding the differential diagnosis of tonsillar affections. He mentions the condition of simple hypertrophy of the tonsils and the effects of such hypertrophy, as well as conditions of lupus or tuberculosis of the tonsils and malignant diseases. He discusses the differential diagnosis of acute follicular tonsillitis, herpetic tonsillitis and ulcerative lacunar tonsillitis. [T. L. C.]

4.—F. C. Larimore reports a case presenting unique specimens of vesical calculi. The stones were eight in number, uniform in size, tetrahedral in shape, hard, smooth, weighing one drachm each, and were taken from the bladder of a physician. The section of one demonstrates that it was formed from a central nucleus, with concentric layers, each formed in the same way. When all of the stones are matched together a complete hemisphere is formed. A history of the case and report of the opera-

tion shows that there was residual urine in the bladder for a long time; hence the stones were always in a fluid medium. They were removed by a superpubic cystotomy. The stones were all in one place in the bladder, like eggs in a bird's nest. [T. L. C.]

MEDICAL NEWS.

September 14, 1901. (Vol LXXIX, No. 11.)

1. The President's Case.
2. The Garfield Case; A Summary of its Important Features.
3. A Case of Foreign Body in the Esophagus. RUSSELL S. FOWLER
4. Infantile Atrophy. JOHN LOVETT MORSE.
5. The Treatment of Cystitis. CHARLES CHASSAIGNAC.
6. Medical Treatment of Diabetes Mellitus. ARCHIBALD DIXON.

3.—R. S. Fowler reports three cases of the above condition in which esophagotomy was finally resorted to after other efforts at dislodging the coin had failed. In one case the coin was not found by operation, but appeared later at stool. So far as the author's experience goes he recommends complete anesthesia in children; the use of extremely flexible instruments, particularly in children; the lowering of the patient's head as the foreign body approaches the pharynx to avoid of its falling into the larynx; the constant visual supervision of the instrument through the fluoroscope; and finally, that such instrumentation should always precede any operative attempt at removal. [T. M. T.]

4.—J. L. Morse gives the diagnosis of infantile atrophy as follows: The condition is to be differentiated from starvation, wasting secondary to functional or organic disease of the stomach or intestine, congenital syphilis and disseminated tuberculosis. The differentiation from starvation due to congenital deformities is self-evident; that from starvation due to insufficient but suitable food is also plain. The rapid gain when sufficient food is given will settle any doubt. That from starvation due to food of improper character can usually be readily made by a careful consideration of the food in question and by a rapid improvement when a suitable food is given. The differentiation from gastro-intestinal diseases associated with wasting must often be a difficult one, as infantile atrophy is frequently complicated by them. In them, however, the wasting is not the one prominent symptom, as it is in infantile atrophy. It is, moreover, not the earliest, but a late symptom, always following symptoms of gastric or intestinal disturbance. Vomiting and diarrhea are more common. The stools show evidences of indigestion and inflammation not present in those of infantile atrophy. The abdomen is, as a rule, distended. The temperature is usually elevated. There is fretfulness and sleeplessness instead of apathy. The course is not so progressively and uninterruptedly downward. Infantile atrophy in the vast majority of cases occurs in the first six months, and rarely after the first year; the other conditions occur at any age. The history of syphilis in the parents and the presence of other signs of syphilis, active or inactive, make the diagnosis from syphilis with emaciation easy. The differentiation from disseminated tuberculosis, however, is frequently difficult and at times almost impossible, for in the tuberculosis of infancy the local symptoms are subordinate to the general. A family history of tuberculosis or of continued exposure is of certain, but not of great importance. So also is doubtful milk supply. The temperature is likely to be elevated in tuberculosis, but is not always. On the other hand, in some cases of infantile atrophy, especially if complicated, there is fever. Diarrhea cannot be considered as pointing especially to tuberculosis of the intestines, as it may as well be due to some complicating condition. Enlargement of the spleen is in favor of tuberculosis. Enlargement of the liver may occur in either. Rales are almost always present in the lungs of cases of a complicating bronchitis. Solidification of the lung is the most important point in the differential diagnosis, except in the rare instances in which the tubercle bacilli can be demonstrated in the sputum or feces. Even solidification, however, may be due to a complicating bronchopneumonia. [T. M. T.]

5.—In the treatment of cystitis, C. Chassaignac, before considering the treatment, always takes into account the

etiology of the various clinical types, namely: (1) Gonorrheal cystitis. (2) Tuberculous cystitis. (3) Cystitis of urethral stricture. (4) Cystitis of prostatitis. (5) Cystitis of calculus. (6) Cystitis of tumor. (7) Traumatic cystitis. (8) Cystitis by direct infection. (9) Descending cystitis. (10) Cystitis from ingestion of certain irritants. A mere enumeration of them suggests what is in all cases the first indication, namely, the removal of the cause when possible. However, before taking them up *seriatim*, it will be useful to study briefly the general indications applying to a greater or lesser degree to all forms of cystitis. [T. M. T.]

6. A. Dixon, in speaking of treatment of diabetes mellitus from a medical standpoint, says that we can hardly afford to ignore the question of diet. The main object to be accomplished is the reduction of carbohydrates as far as may be. It is not possible to do this absolutely for any length of time, nor indeed does he think it necessary, but by a careful selection of food the amount of starch can be reduced to a very small quantity. It is, of course, necessary in each case to write out and give to the patient careful directions as to diet, but we all know how distasteful a strictly diabetic diet becomes, and how difficult a matter it is to confine a patient to it, in fact, he thinks this is rarely, if ever, done, except in cases of exceptional severity when the patient is himself alarmed. In mild cases, when the amount of sugar is small and is, as so often happens, associated with gout, all that is needed is that the patient be given a diet that is suited for that malady. Cases are often encountered in which, although much starch occasions much glycosuria, a small quantity will not do so, the amount of the disturbance of the glyco-genic function being slight. It is, therefore, important to discover in case of any individual patient how much, if any, starch he can consume without increase of sugar in the urine. He should be allowed to take a certain small quantity of starchy food, and, if no increase of sugar results, a little more may be given, and in this way can be learned what quantity of starch it is safe to give. In a number of the author's cases there was no strict adherence to rules of diet, and in two cases the patients took both bread and potatoes and other interdicted things as well.

[T. M. T.]

THE NEW YORK MEDICAL JOURNAL.

September 14, 1901. (Vol. LXXIV, No. 11).

1. The Lane Lectures on the Social Aspects of Dermatology. MALCOLM MORRIS.
2. Professor Max Schuller's Views on Malignancy. JAMES EDDY BLAKE.
3. The Clinical Diagnosis of Carcinoma of the Esophagus, and the Techniques of Gastrostomy. CHARLES GREENE CUMSTON.

2.—Charles Greene Cumston divides carcinoma of the esophagus into five groups: (1) In this form of disease the first symptom which declares itself is the difficulty that the patient experiences in swallowing solid food. The dysphagia occurs suddenly in some instances, while in other cases it develops slowly, becoming more and more intense, while the pain increases as the stricture produced by the neoplasm becomes tighter. When the stricture has closed to such a degree that food can no longer enter the stomach, the esophagus becomes filled with the alimentary mass and dilates above the obstruction, forming a pocket which varies very much from one case to another. In a case that was under the author's care an hour-glass dilatation was found at the autopsy. (2) By far the most frequent, may be properly called the tracheo-bronchial type, not only on account of the extensive and intimate relationship that the esophagus has with the trachea and the large bronchial tubes, but also on account of the tracheobronchial lymphatic glands which are often involved by a metastasis, resulting in a disintegration and secondary infection occasionally, from which fistulae between the trachea and esophagus or the esophagus and the bronchial tubes are formed. Symptoms of compression are first noticed when the neoplasm in the esophagus begins to press on the posterior aspect of the trachea, and finally almost completely occludes the lumen of the latter, and ultimately results in a permanent dyspnea with pulmonary emphysema; (3) This group of cases may be called, the

laryngeal, and under this title may be classed two different forms, one being the result of extension of carcinoma of the mucous membrane, muscles and cartilage of the larynx, while the second is due to the compression or inclusion of the laryngeal nerves. The first type is the most infrequent, because primary carcinoma of the esophagus rarely makes its appearance at the level of the larynx, but when both organs are affected the neoplasm usually begins in the larynx and only invades the esophagus. This type is only a modification of the tracheal variety, and has the same symptoms, namely, dyspnea, and attacks of coughing and suffocation. The second type is not much more frequent than the one that has been considered, and is always extremely serious. The special objective symptoms are produced by a paralysis of the inferior vocal cords; (4) The pleuropulmonary complications following carcinoma of the esophagus may be produced by the extension of the malignant mass to the lung, but often also pneumonia or pleurisy or a combination of both is met with, although the lung and pleura are free from the neoplasm. When extension of the growth does occur, we may have either a serous or a purulent pleurisy, a hydropneumothorax or pneumonia. Usually one finds a mixed lesion: there are a few carcinomatous nodules disseminated in the pulmonary tissue which have become the nucleus of hepaticization, but carcinoma can never reach the lung without involving the pleura, and consequently, along with a pulmonary lesion, there is always a pleurisy, usually with a bloody liquid. This pleurisy may be encysted and give stethoscopic signs of pneumonia; (5) The fifth and last group of carcinoma of the esophagus which the author describes is the cardiovascular form. The heart and large vessels are in too intimate relation with the esophagus to escape lesions in many cases where this organ is the seat of carcinoma, and consequently we often meet with complications either of the heart or pericardium, the aorta, the carotid, the inferior thyroid artery, the brachiocephalic trunk, or the vena cava or the subclavicular veins.

2. Some Cases of Cancer Treated by the X-Rays. FRANCIS H. WILLIAMS.
3. General Anesthesia in Operation upon the Nose and Throat.—Nitrous Oxide, Chloroform and Ether. F. B. HOPKINS.
4. Eosinophile Leukocytes and Nuclein Bases. EDWARD T. WILLIAMS.
5. Discussion Upon Climatic Treatment of Pulmonary Tuberculosis versus Home Sanatoria. S. G. BONNEY.

2.—The cases of carcinoma that have been treated by Williams with the X-rays include, not only the smaller and lesser forms, but also some that were believed to be inoperable, for example, a carcinoma of the eyelid in an old man. Microscopic examination has been used, not only to make the diagnosis, but also for the purpose of observing the changes that were taking place in the growth during the treatment. The tumor was a typical, rapidly growing epidermoid carcinoma and, after the treatment had been progressing for some time, the microscope showed that the central portion of the ulcerated area was free from carcinoma cells, but that near the edges of the ulceration there were still a few islands of epithelial cells. The persistence of the epithelial cells in this area may have been due to the fact that the periphery of the growth was in some way protected from the X-rays by the lead shield used to prevent the rays from striking the healthy skin. In treating carcinoma of the skin with the X-rays there is danger of producing an X-ray burn. Williams' experience has led him to believe that the X-ray may be used in the early stages of skin carcinoma. [J. M. S.]

3.—Hopkins finds that nitrous oxide is a safe anesthetic and that it is not disagreeable to the patient, either while he is taking it or in its after effects. The short period of the duration of the anesthesia produced by it renders it of doubtful utility in operation on the nose and throat. Chloroform is particularly dangerous when administered to children who suffer from adenoids. The author has had no serious after effects from the use of ether. He recommends the rectal administration of ether after the anes-

themia has been induced by the usual method of inhalation. [J. M. S.]

4.—In 4 of the eosinophilous diseases, namely, leukocythemia, asthma, helminthiasis and trichiniasis, eosinophilic leukocytes are constantly associated with all the nuclein bases either in the blood, the marrow, the glands, the organs, the tissues or the excretions. The presence of the nuclein bases in eosinophilia proves that there is a decomposition of nuclein going on somewhere in the body. But nuclein is only to be found in nuclein-bearing cells. According to Williams, nuclein-bearing cells, therefore, are undergoing decomposition and these cells are the eosinophiles themselves. [J. M. S.]

5.—Bonney is an earnest advocate of the value of climate in the treatment of consumption and he is, likewise, heartily in support of a suitable regime of daily life and management, but believes this to bear to the preceding condition the relation chiefly of a most valuable adjunct. While each separately constitutes an exceedingly important factor in the effort to secure arrest, they are, nevertheless, mutually interdependent, with the best results obtained only through their conjoined effect. He believes, however, that life in a sanatorium is not the *sine qua non* for the observance of the strictest disciplinary system of regimen. The prevailing tendency to provide home sanatoria for all classes and to repudiate the established facts of climatic influence cannot fail, in the end, to prove a most unfortunate delusion. [J. M. S.]

7. The Relation of Unbalanced Physical Development to Pubertal Morbidity as Shown by Physical Measurements. W. S. CHRISTOPHER.

1.—Park says the only hypotheses concerning cancer that are worth mentioning are the dietetic, the embryologic, the irritation and the parasitic theories, and that the dietetic theory is of importance only in case we may succeed in maintaining the parasitic nature of the disease. He believes cancer to be due to parasites, and that these parasites have been discovered in the Buffalo laboratory. The arguments adduced in favor of the parasitic hypothesis are those by analogy, comparative pathology, the study of well-known affections which produce tumor formations, the study of metastases, the local infectivity of the cancerous lesions, and the microscopic appearances of the growths. Tumors in plants are due to parasites as well as tumors that are common in the lower animal. The higher we go in the animal scale the more closely these tumors resemble those of human beings. By a study of the infections which produce tumor formation one of the strongest arguments is set forth. This is not a question of bacteria, but a question of organisms, about which we as yet know very little. In answering the argument against the parasitic theory, that the duration of cancer is too long to permit its recognition as an infectious disease, the facts that cancer is often as rapid as tuberculosis and more rapid than syphilis or leprosy, are given. He claims that Dr. Gaylord had absolutely produced adenocarcinoma by inoculation in animals. The organisms of cancer appear to belong to the protozoa. They undergo ameboid movement, but a minute description of these organisms can scarcely yet be given. The most successful way that has yet been devised to cultivate them is to deposit them in collodion sacks in the living animal. He says that if cancer be recognized and be removed thoroughly it can be absolutely cured. If we establish the parasitic cause it is not too much to hope that some agent, be it vegetable or mineral drug, or animal antitoxin, may yet be discovered by which the ravages of the disease may be checked or prevented. [F. T. S.]

2.—Powers deplores the delay in diagnosis of carcinoma. This is due to the non-perception of the patient or to his fear of being given an unpleasant report, or to a lack of

recognition by the medical attendant. The first may be met by a systematic instruction of the laity through suitable lectures, magazine articles and the like. If the blood exhibits no giant and nucleated forms of red corpuscles and no leukocytosis, we may exclude the presence of pernicious anemia. Tentacular and pseudo-parasitic forms of red corpuscle, with abundant hematoblasts, point to cancer. Marked anemia without an anemic murmur suggests cancer. That the hemoglobin may be reduced is true of simple gastric ulcer as well as cancer. Of seventeen cases of cancer of the stomach a digestion leukocytosis was found in four, and hydrochloric acid persisted in certain instances. The discovery of the *Boas filiform bacillus* in large amounts in the stomach contents justifies the diagnosis of cancer. The diagnostic reaction from the use of cancer serum is also mentioned. This is prepared from the parasite of the so-called cancer of trees, and is without effect when injected into animals; but in man and animals with cancer, injections produce a rise of temperature of from 1 to 3 degrees in from two to four hours. Larger doses produce chills, rapid pulse, cardiac palpitations, headache and thirst; the crisis terminates at the end of some hours in polyuria and profound sleep. Auto-inoculation as an aid to the early diagnosis of cancer is discussed. Concerning the microscopic examination, he says that experienced surgeons resort to trial excisions in suitable doubtful cases. Some claim this to be dangerous because of the rapid dissemination which the excision may initiate, while all recognized the element of error which may be present in an individual instance. The writer believes that trial excision should always be avoided, if possible, and that it is best to always be prepared for immediate operation. The greater the surgeon's experience, the greater reliance will he be able to place on his general estimate of the individual case. [F. T. S.]

3.—McElroy discusses some phases of malaria. The author reports a case of malaria which occurred in a strong negro, 60 years of age. The patient developed coma, which lasted for seven hours. During the illness large bullae developed on each knee. The blood examination revealed estivo-autumnal parasites. The fever subsided after vigorous anti-malarial treatment in seventy-two hours. After four weeks the skin where the bullae appeared became gangrenous. The patient finally recovered. The author states that in the Mississippi Valley a few cases of pernicious malaria have been reported, in which the benign parasites were responsible for the symptoms. In the author's experience he has found that a large majority of malarial fever occurring in the Mississippi Valley were of the estivo-autumnal character. He also emphasizes that, as a rule, two predominating broods of parasites are responsible for grave symptoms. In the author's experience he has not found the negro immune, but, on the contrary, the comatose, convulsive, cardiac, gastric, choleric, hemorrhagic and hemoglobinuric types occurred in negroes, and in some of the cases death resulted. The article is concluded with a report of a case of estivo-autumnal malaria, with multiple gangrene, which occurred in a mulatto girl, four years of age. [F. J. K.]

4.—Osborne suggests the term **medical shock** as meaning a condition due to many acute chronic diseases, and characterized by rapid heart action, irregular, soft, and perhaps diastolic or intermittent pulse, incomplete inspiration without actual dyspnea, and precordial oppression. The author believes that we are justified in using the term, as we are using the term, surgical shock. He contends that this condition is brought about by vasomotor paralysis, except perhaps in some very acute diseases, where there may be excessive hemolysis. The treatment of medical shock is laid down on the same lines as that of surgical shock. [F. J. K.]

5.—Boston has made a series of investigations to show that tuberculosis may be spread by coughing. He found that tuberculous patients, during the act of coughing, would eject a spray of fine droplets of sputum. He collected this spray of sputum on a mask, placed in front of the mouth and nostrils. He studied 50 cases of unquestionable tuberculosis. In 38 of these he was able to detect tubercle bacilli in variable numbers in the spray ejected by coughing. The author suggests that this method of collecting may be of some value in the diagnosis, particularly in those cases of tuberculosis where the chest examination is unsatisfactory, and the sputum is swal-

lowed. We are reminded that it is probable that a number of acute infectious diseases may be spread by coughing. [F. J. K.]

6.—Williams remarks the increase of cancer in the various countries. From the standpoint of treatment by the X-rays, he divides cancers into the external and internal forms, and discusses the external form only. Diagnosis of all cases has been made by a microscopic examination. He has treated cases of epidermoid cancers, typical epitheliomas and rodent ulcers, and also cases which have had the clinical appearance of beginning cancers, but which, under the microscope, were found to be plasmoma or simple cases of ulceration, necrosis or inflammation. He says we have in this new agent a useful therapeutic agent for all forms of external growths except syphilis. All forms of growths yield to the treatment by the X-rays. Great care is necessary in carrying out the treatment; the surrounding parts should be protected from the action of the rays, and the treatment should not be so vigorous as to cause an X-ray burn. The advantages of this method are no pain, healing without a burn, some cases improve after a certain number of sittings without further renewal of the treatment, treatment can be carried on without interfering with the work of the patient, and it causes a cessation of pain and foul odor from ulcers. Its disadvantages are: The necessary apparatus is expensive and difficult to use, and that the treatment must be continued for some weeks. He cites three cases which were cured. These were an epidermoid cancer of the lip, an epithelioma of the eyelid and a rodent ulcer on the side of the nose and cheek. He mentions a fourth case, an epithelioma of the right hand, which is still under treatment, and is markedly improving. [F. T. S.]

7.—Christopher writes on "the relation of unbalanced physical development to pubertal morbidity, as shown by the physical measurements." In this article are included a number of statistical tables. He offers the following conclusions: At the pubertal period there is an exaltation of life processes, which manifests itself not only in an increased rate of growth, but also in an increase of physical power. In girls this exaltation begins at an earlier age and is of shorter duration than in boys. The period of puberty is one of great individualization. During the ages of childhood (including puberty) the range of physical measurements is of uniform distribution above and below the line of average measurements. Morbidity is high at puberty, while mortality is low. The principal morbid conditions of the physical, intellectual and emotional turmoil which characterize puberty are neuroses, psychoses, neurasthenias, cardiopathies, deformities and anemias. An important factor in the production of morbid conditions is unbalanced physical development. This unbalanced physical state occurs during the developmental period of life, and is especially marked at puberty. [F. J. K.]

1.—Will be abstracted when concluded.

2.—Will be abstracted when concluded.

3.—Wharton Sinkler has made a personal canvass by means of letters to the different State and private institutions in Pennsylvania as to the condition of epileptics in

the State. He has had reports of 1,164 cases, and these incomplete returns show that the epileptics bear a proportion of 1 to 5,414 to the population. These are in public institutions. There are probably twice as many who are cared for by their families, so that we are safe in assuming that there is at least one epileptic to every 2000 persons. A large number of epileptics in the different institutions is undoubtedly able to do a moderate amount of work if given the opportunity. A great majority of the cases in asylums and other institutions is insane, but many of this number could be employed, and thus be benefited physically. The benefit of a well-regulated life and constant out-door employments to the physical health of the patients is very great. It has been noted that a very much smaller amount of medicine is required than formerly given. At the Pennsylvania Colony Farm for Epileptics one patient, who had several attacks each day, passed eight months without a seizure. Some patients went an entire year without an attack. A considerable number had one fit instead of a number, as in the past. A decided improvement was noted in the mental action and intelligence of the patients. [T. L. C.]

4.—H. D. Didama presents a paper on *modern experience vs. ancient tradition concerning alcohol as a beverage and medicine*. This author does not use the drug as a beverage nor prescribed it as a medicine. [T. L. C.]

5.—Charles O'Donovan reports upon *atropia as an efficient aid in relieving acute pulmonary edema*. He gives at once 1/100 grain of atropia sulphate, with 1/50 grain of strychnia sulphate. While this is being absorbed, attention can be given to preparations for *venesection*, if this should prove necessary. It is safe to begin, he says, with 1/100 grain of atropia, and repeat it in a half hour or at longer intervals, until the system is well under its influence. He has had excellent results from this treatment, and advises its employment. [T. L. C.]

6.—G. W. McCaskey contributes a note on *bacillus coli communis in a possibly new role as an inhibitor of HCl in the stomach*. A case is reported in which the gastric contents were found to contain almost a pure culture of the *b. coli*. There was not a trace of HCl after a test breakfast. Abundance of lactic acid was present. There were no microscopic evidences of malignancy, either in the shape of cell-structure or a typical mitosis. After washing out the stomach thoroughly, oatmeal gruel was given and the contents withdrawn in an hour. There was not a trace of lactic acid, but 65 degrees of free HCl. A full test breakfast was ordered, and seven hours later a test was made. No lactic acid and free HCl were found. He gives three possible explanations of this phenomenon. 1. The possibility of variation, due to neuropathic conditions. 2. The strong stimulation of gastric mucosa by the irrigation. 3. The removal of immense quantities of bacillus coli communis, which was in this case the undoubted producer of lactic acid. He believes that the growth of the organism acted by means of its metabolic products as an inhibitor of HCl secretions. [T. L. C.]

7.—Howard F. Hansell reports the *eye complications in a case of ankylostomiasis*. The conjunctiva was transparent, the sclera white and bloodless, the cornea clear, the musculature unaffected, the lens and vitreous clear. The fundus reflex was light pink in hue, like that seen in pronounced blondes, although the patient was a decided brunette. Both optic papillae were edematous, their outlines indistinct or lost, and the retinas infiltrated with serum in a small zone surrounding each disc. In the right eye, to the lower nasal side of the papilla, were two small linear extravasations, evidently in the fibre layer of the retina. In the left eye, in the neighborhood of the fovea, was a round hemorrhage, probably subretinal, and a few scattered flame-like extravasations. The retinal arteries were distinguished as nearly transparent lines. Their coats were not thickened nor were the vessels contracted. The loss of coloring matter in the blood gave them a peculiar appearance. It seemed as though they were filled with water rather than with blood. The veins were tortuous and darker in color than the arteries, but much lighter than in health. The blood current could be distinctly seen as it coursed through the veins. Where the vein was inclined toward the observer the contained blood appeared dark, but in the horizontal part of the vessels the blood column reflected much more light. The blood extravasations were not due to ruptured vessels, but rather were a transudation, made possible by its altered constituency. [T. L. C.]

VRATCH.

June 2, 1901. (Vol. XXII, No. 22).

1. On Tuberculosis of the Lymphatic Glands.
B. K. FINKELSTEIN.
2. On the Application of Psychotherapy in Childhood.
H. A. PETERS.
3. Brandt's Method of Treating Diseases of Women, and Some of its Peculiarities.
D. D. SANDBERG-DEBELE.
4. The Economics of Births, Treatment and Mortality.
P. A. GOVORKOFF.

1.—Finkelstein presents a statistical review of 456 cases of tuberculosis of the lymphatic glands treated at the Male Obouchoff Hospital within the last 10 years. According to age, the cases were distributed as follows: Below 10 years, 7; from 10 to 20, 329; from 20 to 30, 97; from 30 to 40, 18; from 40 to 50, 3; from 50 to 60, 2. Of 30 patients in whom the inguinal glands alone were involved only 9 were between 10 and 20; the others ranged between 20 and 50. The greater frequency of tuberculosis of the inguinal region in adults is explained by the supposition that in such cases the virus gains entrance through the genital organs, although concurrent affection of the latter has been observed only in 4 cases. Concurrent affection of the bones or joints was rare. Of 31 cases in which the axillary glands alone were involved, tuberculosis of the bone has been observed only in 4. Of 30 cases of tubercular affection of the inguinal glands of the bones were involved only in 2. Pulmonary tuberculosis was rare, only 51 patients (11.2) having been affected. Scurvy occurred as a complication in 5 cases (1.3%). The following conclusions are drawn: 1. Tuberculosis of the lymphatic glands is a very serious disease, demanding the closest attention on the part of the physician. The appearance of slight enlargements is a grave foreboding of a serious affection. 2. In the incipient stages general systemic treatment alone is sufficient. However, when the glands are glued together, enlarge and begin to suppurate, satisfactory results can be obtained only from an operation. 3. Of the local applications the best is heat. Injections of tuberculin, arsenic, chloride of zinc and nitrate of silver only hasten, but do not cause absorption. 4. Extirpation of the affected glands should be performed with the utmost care. All of the involved tissue should be removed, and the blood vessels first freed from the surrounding tissue to avoid injury. 5. To prevent relapses, general treatment is indicated. All our efforts, however, are frustrated by the terrible conditions under which these patients live and work. It is therefore necessary to introduce broad sanitary measures, which alone can render effective the fight against tuberculosis of the lymphatic glands in particular. [A. R.]

2.—Peters treats of the application of psychotherapy in the treatment of various hysterical neuroses of children, describing a number of illustrative cases. He has employed successfully hypnotic and other forms of suggestion in the following conditions: Hysterical aphasia, enuresis, hysterio-epilepsy, simple hysteria, hysterical chorea, hysterical paresis of the diaphragm, congenital epilepsy, chronic constipation, traumatic neurosis and chorea of Charcot. The best results were obtained in hysterical paresis, and enuresis dependent on hysteria. The author points out the difficulty of recognizing hysteria in children, since many of the essential and characteristic symptoms of that affection are lacking, such, for instance, as hemi-nesthesia, globus hystericus, sudden fits of crying, etc. On the other hand, change of character and disposition, sudden changes from crying to laughing, so characteristic of the hysterical adult, are normal phenomena in a child. Occasionally a grave disease is mistaken for hysteria, owing to the confusing symptoms. In one case the author made a diagnosis of hysteria in a little girl who proved to be suffering from a developing osteo-sarcoma. In another the first stages of myelitis and in a third the beginning of spondylitis were masked by hysterical symptoms. The various methods of inducing hypnosis in children are discussed. [A. R.]

3.—Sandberg-Debele advocates Brandt's method of treating diseases of women, claiming that in it we possess the very best therapeutic agent. The method consists in massage and Swedish movements, and is indicated in various inflammatory processes of a chronic nature. The author employed the method unaided in 25 cases of diverse

affection of the uterus and adnexa with most gratifying results. A detailed history of each case is given and the indications for this mode of treatment fully discussed. [A. R.]

DEUTSCHE MEDICINISCHE WOCHENSCHRIFT.

June 6, 1901.

1. A Case of Foreign-body in the Cardiac Portion of the Stomach, Diagnosed by Radioscopy and Esophagoscopy. Gastrostomy. Cure. G. GOTTSTEIN.
2. Obstruction of a Coil of Small Intestine by Ring-like Adhesion of the Appendix. HERMES.
3. Further Investigations Concerning Dysentery and the Dysentery Bacillus. KRUSE.
4. The Condition of Blood Pressure in the Treatment of Chronic Heart Diseases. SCHOTT.
5. Fatal Stab-Wound of the Heart without Macroscopic Blood Stains on the Knife. FOUCK and PRAUM.

1.—The foreign body in this case consisted of a plate with false teeth which had been swallowed six months before admission, but had given no trouble until three months before. As the course of events afterward showed the plate must have lodged at first in the lower part of the esophagus, but in such a position as to leave an easy passage way for food and drink. Three months afterward sudden intense symptoms of esophageal obstruction set in, probably as the result of the plate's dropping down the cardia itself. These symptoms afterward improved, but pain and difficulty on swallowing, referred chiefly to the region of the cardia were constantly complained of. The relief in the symptoms proved to be due to the fact that the plate had passed the cardiac opening. There was much difficulty in diagnosis as the history seemed strange. No foreign body could be felt with a sound in the esophagus or stomach, and it was suspected that the patient had grown hysterical over the matter and the plate had either never been swallowed or had passed completely through the alimentary tract. By combined esophagoscopy and radioscopy, however, it was learned that on the one hand, there was an ulcer with pus oozing from its depths in the cardiac portion of the stomach near the esophageal opening, and there was, on the other hand, a shadow at about the level of the cardiac orifice that might readily be the plate. It was decided that the plate was at least partly without the stomach, having perforated the wall, and operation showed the correctness of this view. The plate projected somewhat through a fistula very near the cardia, but the greater portion lay outside surrounded by a pus cavity. After opening the stomach, the plate was successfully removed, though with some difficulty. The patient recovered entirely. The situation of the foreign body was unique so far as the literature seems to show. The case is also evidence against Rosenheim's view, based upon anatomical studies, that the cardia lies normally opposite the twelfth dorsal vertebra. In this case the shadow of the plate which was just about at the level of the cardia, was not lower than the 9th dorsal and Gottstein considers that this evidence obtained intra vitam is better than any post mortem evidence; the conditions present were, however, certainly not such as necessarily to indicate the level of the normal cardia. [D. L. E.]

2.—The chief interest in the case is indicated by the title. The appendix was found drawn across the cecum and adherent by its tip. Through the loop thus formed had slipped a portion of the small intestine and the latter had been absolutely firmly caught and was entirely obstructed. The chief interest in diagnosis was between appendicitis with peritonitis, perforating gastric ulcer and peritonitis, and ileus. Appendicitis seemed not very probable as there were no local appendiceal symptoms and there had been none recently at least. The symptoms just preceding the attack and for a long time before had been chiefly gastric and the sudden onset of symptoms strongly resembling peritonitis rendered perforating gastric ulcer probable, though the flat abdomen, the full strong pulse and the very sudden onset indicated volvulus. The operation disclosed the condition mentioned and led to entire recovery. [D. L. E.]

3.—Kruse reports further investigations concerning the bacillus which he has previously described (*Deutsch. Med. Woch.*, 1900, No. 40). In an insane asylum near Düsseldorf there occurred one case of dysentery and three months afterward 15 more cases were observed. The blood serum

of eight persons was examined for agglutination with the previously described bacillus, and reaction was obtained in seven. The eighth was from a patient who had been sick only three days. Kruse previously stated that serum from normal persons might react with the bacillus in dilutions less than 1 to 50. He no longer believes this fully, however, since about fifty healthy persons showed absolutely no reaction in any such dilution, and he thinks now that the persons who were supposedly normal, but had given the reaction had probably had dysentery earlier. He describes the case of his assistant who acquired dysentery very probably as the result of laboratory infection with Kruse's bacillus. Since his stools contained the bacillus in large numbers, his blood serum reacted in high dilution and he had in no other way come in contact with dysentery, nor had dysentery occurred lately in that neighborhood (Bonn). This, Kruse considers a satisfactory case of experimental infection with his bacillus. He thinks the bacillus is found in America also as Spronck reported to him that he had found it in Utrecht in a man recently from America who then had dysentery. Flexner's bacillus differs from Kruse's in that it has slight motion, but there is no other well marked difference and it agglutinated after twenty-four hours with a serum that agglutinated Kruse's bacillus. Kruse believes that his bacillus, Flexner's and Shiga's are all closely related, but not identical, and that numerous organisms capable of causing dysentery will probably be found. (To be Continued.) [D. L. E.]

4.—Schott found after a long series of experiments with Gaertner's tonometer that in cases that did well with the bath treatment the blood pressure rose during the treatment. While cases that did badly showed a fall of blood pressure. The latter cases were of the classes that he has previously stated should not be given Nauheim treatment. He considers that Gaertner's tonometer should be regularly used in cardiac cases; if during treatment the blood pressure rises the treatment is doing good and the prognosis is correspondingly better. If the pressure falls the treatment is probably harmful and the prognosis worse. [D. L. E.]

5.—The case was that of a man who had committed suicide. It was of interest only in that the knife which the wife said he had used was apparently not blood stained. Chemical examination (hemin-test) showed blood in one spot after it had been dry for two weeks. [D. L. E.]

BRITISH GYNECOLOGICAL JOURNAL.

May, 1901.

On Hemorrhage, Hemostasis, and Protection of the Bladder and Ureters in Dealing with Myomata, with Some Remarks on the Choice of Operation and Operative Technique. FREDERICK EDGE.

Edge discusses the various methods of securing blood-vessels and arresting hemorrhage that have from time to time been employed by the different operators in abdominal surgery, including the method of angiotripsy. In hysterectomy he claims, that direct ligation of the vessels is to be aimed at; for this catgut is best because it is absorbed. When direct ligation is impossible, the broad ligaments should be ligatured in sections; the sections should be small, and the uterine and ovarian vessels when seen on the face of the stump should be separately secured. Angiotripsy should be always used for small points, and combined with ligation may be used for large vessels. Clamps for the broad ligaments or *serre-nœuds* for extra-peritoneal stumps are only to be used when ligation is impossible or some secondary action is aimed at, as in vaginal hysterectomy for prolapse, or finally, when rapidity of operation is of unusual consequence. In using catgut, care is required not to include too much tissue in each ligation, not to use too great force, and not to tie any vessels on the face of the stump. Silk is our great reserve when catgut is bad or unsatisfactory to the surgeon. When catgut or silk sutures have been used the after course is usually straight and smooth. From his personal experience in the surgery of myomata, he is inclined to conclude as follows: 1. The vagina should be carefully cleaned and the uterine cavity douched, and even curetted when possible. 2. The essence of all methods is the securing of the arterial supply of the uterus early in the operation. 3. It is essential that the operator should know the anatomy of the uterus and the pelvic organs. 4. He must be ready to perform panhysterectomy in what may appear to be the

simplest case. 5. In panhysterectomy the vaginal attack may, when the cervix is free, remove all difficulty, and in any case facilitates the operation and gives the operator a clearer conception of what he has to do. 6. Panhysterectomy with suture of the peritoneal flaps and care as regards leaving plenty of vaginal mucous membrane is the safest operation, and is the only true and complete treatment of the myomatous uterus. 7. The question of malignant disease (degeneration or recurrence) in the cervical stump is a subject requiring further investigation. [W. A. N. D.]

August, 1901.

A Case of Puerperal Septicæmia, Pyæmia and Insanity.

F. PERCY ELLIOTT.

Elliott describes a case of considerable interest in which puerperal infection seems to have been due to the use of an aseptic vaginal douche on the thirteenth day after delivery, and in which the patient was treated with anti-streptococcal serum and recovered, after death appeared to be inevitable. The history of the case shows that prior to infection there was no septic symptom whatever. The cause of sepsis was undoubtedly some *matrices morbi* lurking in the vagina and conveyed into the uterine cavity by injection. In addition to her septic condition the patient developed a puerperal mania. No local uterine treatment was employed at any time after the initial rigor. There developed inflammation of certain of the joints of the body; these were treated with warm fomentations, and the application of equal parts of glycerin and extract of belladonna during the acute stage, and when the inflammation had subsided, by massage and enforced movements. [W. A. N. D.]

JOURNAL DES PRATICIENS.

July 13, 1901. (15me. Année, No. 28.)

1. The Treatment of Suppuration of the Upper Extremity. MAUCLAIRE.
2. The Therapeutics of Lecithin. H. HUCHARD.

1.—Mauclaire divides his subject into abscess of the fingers and of the hand. In either case they may be superficial or deep. Superficial abscess of the fingers is called paronychia or whitlow, and is generally a reticular, diffuse, subepidermic angioleucitis. This may be erythematous, phlyctenular, peri-ungual, sub-ungual, or retro-ungual. It this goes further, it becomes a subcutaneous paronychia. This may be gangrenous, erysipelatous, diphtheritic, etc. The diagnosis is easy. Osteomyelitis, brain abscess, septicæmia, etc., very rarely occur. The treatment is free incision. Deep whitlows may affect the tendons, the phalanges, or the joints of the fingers. When teno-synovitis occurs, the fingers are drawn up, and immediate incision is necessary. Phalangeal osteomyelitis is frequently secondary, but may be primary. There is much pain, and immediate incision is again indicated. When arthritis occurs, the prognosis is less favorable, as ankylosis generally results. Abscess of the hand may be palmar or dorsal in position. Mauclaire divides palmar abscess into the supra-aponeurotic, which may be cutaneous or subcutaneous, and the sub-aponeurotic, or deep palmar abscess. The cutaneous palmar abscess is erythematous or phlyctenular. There is great pain with subcutaneous palmar abscess, limited especially to one spot. Movement of the fingers is, however, preserved. Deep palmar abscess may be due to lymphangitis or synovitis. The fingers are retracted, and diagnosis is not difficult. Incision and thorough drainage will be necessary in all of these forms of palmar abscess. [M. O.]

2.—Huchard reports a case of diabetes in whom the weight increased and the glycosuria diminished upon lecithin. He has used it also in anemia, chlorosis, tuberculosis and neurasthenia, with good results. The medication is not new, since it was used by Gobley in 1846, and is well described in 1874 in Gauthier's Chemistry. Huchard states that the uric acid excreted diminishes with the use of lecithin. The increase in weight following its employment is marked. [M. O.]

SECOND DAY—EVENING SESSION.

Cancer of the Uterus, with Lantern Demonstrations.—This was a very interesting and profitable demonstration conducted by Dr. Thos. S. Cullen. In introducing Dr. Cullen, Dr. Chown spoke of him as a young Canadian who had gone wrong in having removed to the United States and having never returned. Dr. Chown considered that the experimental work pursued by Dr. Cullen, if done in Canada, would meet with as signal success as that which attended his labors in the United States. For over an hour Dr. Cullen was engaged in showing a large number of excellent lime-light views, the results of microscopic examinations of tissues, each view being lucidly explained by the demonstrator. At the close of his excellent demonstration Dr. Cullen was accorded a hearty and unanimous vote of thanks moved by Dr. Eccles of London and seconded by Dr. Gray of Winnipeg and carried amid great applause.

Skin Diseases, with Lantern Demonstration.—This was another valuable demonstration and was conducted by Dr. Francis J. Shepherd of Montreal. He first exhibited cases of blastomycetous dermatitis and further spoke of a few cases which he had seen of this disease. Views were given also of cases after treatment with iodide of potash. Some interesting views were those caused by eruptions of which he showed two or three due to salicylate of soda. In one of these Dr. Shepherd said the lesions first came out with large welts like urticaria. This is rather a rare form of drug eruption. It appeared after two doses of ten grains each of the drug. One case almost died of acute laryngitis from the eruption in the throat. Amongst other views shown were papular purpura, which is generally associated with rheumatic attacks, psoriasis of the nails, X-ray burns as the result of one application and most interesting were cases of smallpox, one showing pustules upon the palm of the hand. Views of feigned eruptions were also shown. This demonstration proved so interesting to the members that Dr. Shepherd was frequently called upon to give more or go on.

The Varieties and Distribution of Bacillus Diphtheriae and their Clinical Significance.—Dr. F. F. Westbrook of the University of Minnesota presented a paper on this subject, primarily from the laboratory point of view. He exhibited a carefully prepared chart showing in tabulated form the results of numerous examinations in schools and stated the conclusions which he deduced from these facts. Formerly it was believed, that the bacillus remained localized at its point of entrance, but now, within recent years, however, careful observations have showed that the toxins had been distributed throughout the body and the bacillus itself found in organs far removed from the atrium. From evidences of 230 cases of diphtheria at autopsy, observers had called attention to the frequency with which the bacillus of diphtheria was found in the organs of the body. The bacillus and its toxins have been shown to be capable of producing lesions which differ greatly from each other, as in ulcerative endocarditis, meningitis etc. In summarizing Dr. Westbrook said, where each school was reported and where great care was taken in the isolation of clinical cases with typical form, the percentage was very small.

Removal of Hairy Tumor from the Stomach weighing 23 ounces...Specimen. Recovery, by Dr. H. A. Bruce, Toronto.—The subject of this case was a woman aged 26; she had been married six years and had two children. A lump was noticed in the abdomen two months previous to the birth of the last child. Patient had no symptoms. The

lump was about 5 inches in width and it could be lifted forwards. It reached to within 3 inches below the umbilicus. It gave the patient no special discomfort, there being absolutely no symptoms present. Dr. Bruce advised exploratory incision. This was done on July the 22d last at St. John's Hospital, Toronto. On opening the abdomen in the middle line the spleen and kidneys were found in a normal condition, but there was a large mass in the neighborhood of the stomach. The surgeon could make out the mass lying free in the stomach, a portion extending through the pyloric end of the stomach. An incision was made into the stomach and the mass removed. After removing the mass of hair, the opening of the stomach was closed in the usual way.

Hot salt solution was given for two hours and nutrient enemata for six hours. Twenty-three hours after the operation sips of hot water were given by the mouth. Forty-eight hours after operation patient was given one half an ounce of milk and lime water every hour. She left the hospital on the 20th day. The tumor was entirely of hair exactly the same color throughout and the same color as the hair on her head. It was about 24 inches in length, being about 2 inches in diameter at one end and gradually tapering down to a point at the other. Dr. Bruce considered this case rare but offered no solution as to how the hair got into the stomach. There were no evidences of hysteria present in the patient. There are some specimens of hairy tumors in the McGill Museum at Montreal.

THIRD DAY—MORNING SESSION.

A Case of Transplantation of the Ureter for Cure of Uretero-Vaginal Fistula, by A. Laphorn Smith, Montreal.—This occurred in a married woman, thirty-four years of age, who came to Dr. Smith on the 1st of July, 1901. During parturition forceps were employed and the vagina lacerated and ever since there has been a constant flow of urine by the vagina. Operations for her relief had been performed in England without success. Dr. Smith had seen Saenger perform an operation of this character in Leipsic, when he was there three years ago, namely, to open the peritoneum running over the large vessels at the brim of the pelvis and to feel for the artery, see the vein and pick up the third tube which was the ureter. The operation was done in the highest Trendelenburg posture. A very small incision was made in the peritoneum lining the pelvis in the line of the ureter, a silk ligature was passed around it and then the ureter was severed a little above the ligature. The end of the ureter was split open to a distance of a third of an inch. A slit was then made obliquely into the right upper corner of the bladder and the ureter stitched into it, the mucous membrane of the ureter to the mucous membrane of the bladder with very fine chromicised catgut. This is the first time this operation has been done in Canada and Dr. Smith stated that not a drop of urine had passed through the fistula since.

Syphilis as Seen by the Ophthalmic Surgeon.—This paper was read by Dr. F. Buller, Montreal. In commencing his paper Dr. Buller expressed the hope that it would elicit a little discussion. It often falls to the lot of the ophthalmic surgeon to discover the presence of active syphilitic virus where the disease had long been considered cured or that the subject cherished the belief that there was no more to fear from it. The ophthalmic surgeon is scarcely, if ever, called upon to treat the disease in the primary stage. The largest share of his work is in connection with the tertiary period, and in this class of cases the disease has been apparently cured for a long period of time. Dr. Buller considers that the time at which the syphilitic lesion makes its appearance is always a very important element in the diagnosis. Discussing medication Dr. Buller does not believe that the protiodid of mercury at least as ordinarily administered is a reliable anti-syphilitic. He appears to favor the inunction method first and then gray-powder. The following took part in the discussion of this

paper:—Dr. Lafferty, of Calgary; Dr. Muir, of Truro; Dr. Laphorn Smith, of Montreal and Dr. Shepherd, of Montreal, who also condemned the prothiodid-treatment.

The Present Outbreak of Smallpox in America.—This subject was presented by Dr. H. M. Bracken, Health Officer, Minnesota. He outlined the origin and traced the course of many outbreaks in various parts of the State of Minnesota. The case of a porter on the Great Northern Railway, who arrived in St. Paul in March, 1899, was mentioned as the source of the outbreak. He was supposed to have contracted the disease in Seattle, and, when told that he had smallpox, he said that, if so, there was plenty of the same where he came from. Other epidemics were spoken of in various parts of Minnesota with a total of 3,429 cases, and the disease has still many centres in that state. It is impossible to locate positively the source of the present wide-spread epidemic farther than that it spread from the Southern and South-western States into North Dakota, Minnesota, Nebraska, Montana and Texas. Dr. Bracken showed that returning soldiers from the Philippines were not responsible for its introduction. He suggested that it was probably imported into the United States by Cuban refugees before war broke out between that country and Spain.

An interesting discussion took place on this paper. Dr. Russell Thomas wanted to know where the best vaccine was manufactured, a product that could be relied upon.

Dr. Inglis, formerly Medical Health Officer, Winnipeg, related his experience in the schools of Winnipeg, and spoke of some of the bad results resulting through impure vaccine.

Dr. Bracken in reply:—Vaccine was often spoiled by not being kept in proper temperature, as it was frequently being shipped in cans which were too hot, and subsequently kept in warm offices. The health commissioner of Minneapolis kept all his vaccine in an ice box, but, of course, not frozen, and had obtained good results. Replying to a question in regard to isolation Dr. Bracken favored eighteen days quarantine.

The Necessity of a Recognition and Isolation of Trachomatous Patients in Canada.—In the absence of Dr. W. Gordon M. Byers, Montreal, Dr. C. F. Martin, of the same city, read this paper. The paper recited the history of a young girl from Glengary County, Ontario, who came to the clinic at the Royal Hospital, Montreal, with a most intense condition of granular lids. She had been unable to open her eyes properly for months past, and her vision was reduced to the counting of figures. The seriousness of her disease had not been recognized at home as she mixed freely with other members of the community. Another case was referred to in the County of Leeds, and in this case as well no precautions had ever been taken to prevent the spread of the disease. Dr. Byers believes that there are many unrecognized and untreated cases scattered here and there throughout the Dominion. The disease is said to be prevalent in districts of Manitoba and certain centers in the eastern counties of Ontario and others in Quebec. The trachoma problem has had to be faced by one Government in Europe and the matter has been brought to the attention of the Dominion Government which has not yet taken any action in the matter. Dr. Montzambert stated that the question of exclusion of trachomatous immigrants had been under consideration by the Government for sometime. He considered these people somewhat undesirable immigrants. (To be Continued.)

To Abort Gonorrheal Infection.—Zydowski (Narzyn Lekarskie, March, 1901; *Urolog*, Vol. XXII No. 17) claims that gonorrhea when seen early may be aborted by a 10% solution of nitrate of silver. The urethra is washed with a solution of boric acid anesthetized by a 10% solution of cocaine, and thoroughly swabbed by means of a cotton tampon saturated with the nitrate of silver solution. In one case the gonococci disappeared from the discharge on the following day and complete cure resulted in 12 days.

British Congress On Tuberculosis

Continued from Page 445.

A Plea for Seaside Sanatoria for Children Especially for the Prevention and Treatment of Scrofulous Complaints, by Sir Hermann Weber, M. D. In former times the so-called scrofulous diseases were much discussed by the medical profession and the public, but comparatively little attention is paid to them at present, while the more fatal pulmonary tuberculosis commands general attention. Yet there is good reason why scrofulous affections should in an equal measure engage our sympathy and attention, firstly, because they are likewise of tubercular nature and intimately allied to other forms of tuberculosis; and secondly, because they cause infinite suffering and misery to the patient and often cause death or invalidism or a crippled state for life. By treating scrofulous affections we therefore not only endeavor to cure the existing diseases, but also to prevent pulmonary tuberculosis.

The principal means of cure are:

Life in the open air; Good food adapted in quality and quantity to the patient's condition; Hydrotherapeutic measures, such as bathing in the open sea or in tepid sea water, friction of the body with cold water, etc.;

Active or passive exercise or rest in the open air, regulated according to the nature of the affection.

Surgical treatment is required in some cases, and is more successful in the pure air of the seaside than in inland towns; but the majority of diseases of bones and joints, of enlargements of glands and scrofulous ulcers, heal without active operative interference, though bandages are often indispensable.

Such treatment cannot be carried out at the homes of the children of the poor, and frequently even not at the hospitals of large towns; but in the pure air of the seaside (and also of inland places, especially at high elevations) the treatment, if commenced early, almost always results in complete cure.

Those who are rich can make the most necessary arrangements in private houses or establishments, but the children of the poor have no chance excepting in public sanatoria; and for the great majority of them, sanatoria at the seaside are preferable to those inland, on account of the more vivifying effect of the sea air, which undergoes constant changes by the regular local currents of air and by the stronger general winds, and on account of the facility of bathing in the open sea or in tepid sea water. Experience shows that at the seaside the energy of the nervous system, the appetite and digestion, and the whole organism are more rapidly improved than at inland localities. Inland sanatoria, however, can likewise be rendered most useful, and are, indeed, preferable in cases of scrofulosis complicated already with pulmonary tuberculosis, or in cases of pulmonary tuberculosis alone, most of them bear high winds badly. Localities situated at high elevations, as for instance Samaden, exercise a very beneficial influence, not only on pulmonary but also on glandular affections, and on the so-called surgical tuberculosis of joints and bones. This remark is, however, not to be understood as if we did not recognize that great results can be obtained at well situated and well managed sanatoria in lower inland regions. Great and welcome lessons, for instance, are to be learnt from the benefit effected by the "Cuvre d'Ormesson," at Ormesson and Villiers-sur-Marne, near Paris.

As the subject is so very large, we will confine ourselves at present to the sea-side sanatoria for children, as means of prevention as well as cure. Although we must attend to diseases already developed, we must, if possible, not wait till the scrofulous or tuberculous disease is already fully established, but must begin our treatment at the first indi-

eations, when we can gain in two months what in advanced cases barely can be effected in two years.

The poor children who are most benefited, and who specially require the sanatorium treatment, are those affected with:—

1. General weakness and deficient nutrition.
2. Tardy and imperfect recovery from various acute diseases such as measles, whooping cough, scarlet fever, diphtheria, influenza, etc.
3. Anemia.
4. Rachitis.
5. Scrofulous and tuberculous swelling of the lymphatic glands.
6. Scrofulous and tuberculous inflammation of the joints, including hip-joint disease and Pott's disease.
7. Adenoid affections of the throat and nose.
8. Scrofulous ophthalmia.
9. Scrofulous skin diseases.

For the treatment of the majority of the cases it is not sufficient to use any ordinary house, but we require a properly arranged sanatorium which must possess large rooms with abundance of light and air, with windows from the ceiling to the ground, through which the patients' beds can be moved on the adjacent balconies or terraces; the patients who cannot walk must lie there from morning to night, and many with advantage also, with proper shelter, during the night in fairly good weather. The rooms for meals and games must likewise be large and airy. Pavilions of moderate size, of one or two stories only, are preferable to large blocks having two or three stories. A pavilion for isolation of infectious cases is a necessity, and a well-arranged operating room is likewise indispensable, although in most cases, if taken early, the necessity of operations can be avoided. Boys and girls ought to be in separate pavilions when older than five years, but may be in the same rooms up to that age.

There ought to be on the sea-shore sheds open on two sides, with rotatory arrangement, for shelter against wind and rain, and to some degree also against too fierce a sun. These shelters are especially necessary and must be numerous, if the balconies for lying out are inadequate, or too far away from the actual shore. To these shelters the little patients who cannot walk must be carried on comfortable kinds of bed-stretchers, and remain there during the whole day.

There must be good arrangements for bathing in the open sea and for tepid sea-water baths, to be used in winter as well as in summer. The resident medical officer must prescribe the diet for every single case, as also the nature and amount of walking and playing, and of Swedish or other gymnastic manipulations, particularly for spine or joint cases.

The beneficial effect of sea-side sanatoria can be greatly increased by providing each sanatorium with a *hospital* or *sanatorium boat*, arranged for the accommodation of the sick children, on which, in suitable weather, the invalids can be taken out to the open sea for shorter or longer periods of the day, since it is indisputable that the air on the high sea itself has a more powerful effect on the organism than that on the shore.

The duration of the stay of patients at the sanatorium ought not to be fixed by fast rules, but must depend on the nature of the case, and be left entirely to the judgment of the medical attendant. It may vary from a few weeks to a few years. To limit it to two or three months by the rules of the institution is absolutely wrong. If the patients are admitted at the beginning of the disease or at the first signs of the threatening, a short term will mostly suffice; while advanced cases of hip-joint disease or Pott's disease may require years, and ought not to be discharged before the cure is as complete as the circumstances admit.

Another mistake which is made at many sanatoria is the restriction of the treatment to the warmer months of the year. Although the weather at the northern sea resorts is not always agreeable during winter and spring, the patients at seaside sanatoria are under infinitely better influences

than that in their homes, or even in ordinary hospitals or infirmaries in crowded towns. The patients sent home during winter lose there often more than they had gained at the sanatorium during the summer.

The number of children who require sanatorium treatment at the seaside is very large, and the number of beds available for them in England is very small. There are perhaps three hundred beds in the seaside sanatoria of England, while five thousand would certainly not be too many. Every hospital for sick children ought to have a seaside branch. It is almost incredible that there should be this strange defect in the hospital accommodation of England, especially when we reflect that the whole of the United Kingdom has such splendid sea-coasts, and when we further consider that England was the first country to awake to the great importance of this matter by establishing, on the suggestion of Dr. Lettsom and Dr. Latham, the General Sea-bathing Infirmary at Margate in 1791. The next country to move was Italy, which half a century later founded a sanatorium at Viareggio (1841); and France followed in 1874 by the sanatorium at Cette. While France has made great progress, and deserves the highest praise for her enlightened philanthropy, England has remained almost stationary in this matter. The town of Paris alone maintains in its sanatoria at Berck-sur-Mer about 1,034 beds for scrofulous and rachitic children all the year round, and has also many beds in several other seaside sanatoria on the French coasts. At Berck-sur-Mer, in addition, the benevolent Rothschild family gives perfectly gratuitous treatment to one hundred children in the beautiful Hôpital Rothschild, likewise summer and winter. France has numerous other seaside sanatoria along her different coasts, mostly under the direction of the "Assistance Maritime des Enfants Scrofuleux et Rachitiques" and "l'Œuvre des Hôpitaux Marins." Independently of these sea-side sanatoria France possesses, as already mentioned, the admirable inland sanatoria for tuberculous children at Ormesson and Villiers-sur-Marne (Œuvre d'Ormesson).

How is it that England, with its wonderful sea-coasts, and with its many excellent institutions for the sick, erected and maintained by private gifts, neglects this important matter? We cannot think otherwise than that the crying need for help and the possibility of bringing this help, are unknown to the philanthropists of this country, men as well as women. If they were aware of the great sufferings which the poor children affected with Pott's disease of the spine, with hip-joint disease, with caries of bones, or with tuberculous inflammation of joints, undergo in their wretched homes, and how large a proportion of them become consumptive later on, or cripples for life, or die after protracted misery; and if they knew, at the same time, that the majority of them can be cured entirely, and that many of the others can be restored to such a condition that they can earn their bread and can enjoy life, provided they are sent early enough to a sea-side sanatoria, many philanthropic persons would surely assist in supplying means to found numerous such establishments. It may be difficult to obtain all the means required by private benevolence; but the subject urgently demands also the attention of public bodies, such as the County Councils and the Poor Law organizations. Associations like the Trade Unions ought likewise to feel the obligation to contribute their share towards the cure of the sick children of their members. The subject is so important and so large that I venture to suggest that an "Association for the Erection of Sea-side Sanatoria" should be formed, as a sub-division of the "National Association for the Prevention of Consumption and other Forms of Tuberculosis."

Two Cases of Senile Chorea.—A. Iarosinsky (*Czasopismo lekarskie*, March, 1901; *Vratch*, Vol. XXII, No. 19) reports two cases of chorea in a brother and sister, 65 and 63 years of age, respectively. In both the affection dates back about 20 years. [A. R.]

Special Article.

THE CASE OF PRESIDENT MCKINLEY.

William McKinley, twenty-fourth President of the United States, died at Buffalo, New York, on September 14th, 1901, from the effects of a pistol shot wound of the abdomen at the hand of an assassin. Few rulers, crowned or uncrowned, have ever been the objects of such respect, affection and solicitude as were displayed for him during the week he lay battling with death.

With these facts in mind, with a consciousness of the fierce glare of public opinion concentrated on them, the distinguished patient's surgeons accepted their tremendous task. They saw their plain duty and met it, irrespective of the immeasurable enormity of the responsibility they shouldered. It was not the difficulty of the operation, but the fact that the censure of a nation would fall on him who made the slightest mistake in judgment or technique that required the nerve to perform it. There was no delay to share responsibility, and no fastidious red tape. Within an hour of the reception of his wounds the illustrious patient was operated upon in the Emergency Hospital in the Exposition grounds. That this was possible can but reflect great credit on the medical management of the Exposition. Dr. Matthew D. Mann, Professor of Obstetrics and Gynecology, University of Buffalo, performed the operation. His first assistant was Dr. Herman Mynter, Professor of Operative Surgery, University of Buffalo. Dr. John Parmenter, Professor of Anatomy and Clinical Surgery, University of Buffalo, acted as second assistant, and Dr. E. Wallace Lee, of St. Louis, Mo., served as third assistant. Dr. Eugene Wasdin, of the Marine Hospital Service, administered the ether. Dr. Prestley M. Rixey did not reach the scene until after the operation had been started. Dr. Roswell Park, Professor of Surgery, University of Buffalo, had gone to Niagara to operate. He was summoned to the hospital and arrived on a special train in time to assist in the completion of the operation.

The bullets were fired from a revolver held in front of the President by a vile thing having the appearance of a man, a Frankenstein monster whose bread and salt came from the country he so sorrowfully afflicted. One ball struck the sternum on the left side, between the second and third ribs. It was abstracted without difficulty and caused no serious injury. The fatal bullet penetrated the abdomen at a point two and a half inches to the left of the median line and at a level of about one-half inch above the umbilicus. An incision, five inches in length, was carried into the abdomen and the trajectory of the bullet followed. A perforation in the anterior wall of the stomach was found and sutured with fine black silk. The intestines were then inspected, but no injury was found. The perforation in the posterior wall was over an inch in diameter, with irregular lacerated and contused edges. This also was sutured with fine silk. The fact that food had not been ingested for a least three hours before the injury, together with the promptness, celerity and dexterity of the surgeons, accounts for the little peri-

toneal contamination present. A copious irrigation of surgical salt solution was next employed and the abdomen closed without drainage. Through and through sutures of silk-worm gut were used and the fascia brought together with catgut. During the anesthetic sleep an ambulance conveyed the august patient to the house of Mr. John Milburn, President of the Pan-American Exposition. Three male nurses from the United States Army Corps and three female nurses were selected to administer to the President's wants. The male nurses were selected from those on duty with the Field Hospital Exhibit of the Army Medical Department at the Exposition. They were Acting Hospital Steward Palmer A. Eliot, Private Ernest Vollmeyer and John Hodgkins, all of whom graduated from the School for Hospital Corps men at the Army General Hospital, Washington, D. C. Eliot is also a graduate of the Bellevue Hospital Training School, and Vollmeyer a graduate of the Presbyterian Hospital of New York. Hodgkins has had a long experience of nine years in military hospitals. "The efficiency of these men is such as to have elicited much favorable comment from the staff of attending surgeons." We are glad to note the marked competency of the Army Hospital Corps in meeting the great duty which devolved upon it, and also the rare commonsense displayed in not excluding male nurses. The female nurses were Miss Helen Mohan, a graduate of the Buffalo General Hospital Training School; Miss Conley, a graduate of the Buffalo Hospital Training School; Miss Hunter, Mrs. McKinley's nurse, and Miss Grace McCullough, of Baltimore, all of whom deserve the highest praise for their part in the unsuccessful campaign against the Grim Reaper.

The President's faithful physician, Dr. Rixey, and one of the surgeons remained in the house each night, and all the physicians and surgeons consulted three times each day. Dr. Charles McBurney, of New York, was sent for as a consultant; he arrived the next day.

There was apparently no profound shock following the operation. The pulse, however, always remained above the normal, but as the period for peritonitis slowly dragged by without any evidence of this dreaded complication, anxiety and doubt dissolved and crystallized themselves into the conviction that recovery was assured.

At frequent intervals bulletins, brief, plain and simple, telling the progress of the case, were issued, signed by Drs. Rixey, Mann, Park, Mynter, Wasdin and McBurney, and by Mr. George B. Cortelyou, Secretary to the President. They contained no opinion, nor made any prognostication. The phantom of tetanus, injury to the pancreas, kidney or thoracic duct, and necrosis around the bullet tract, as is sometimes seen in diabetes and in other debilitating diseases, and indeed in individuals otherwise healthy, skulked in the background and must have haunted the brains of the surgeons. Retroperitoneal abscess, uremia and the condition of the heart we heard mentioned frequently. There was scarcely room in one's mind, nor time, to consider the remoter possibilities. And here the newspapers come in for honorable mention. With a few yellow exceptions they told the whole truth, and nothing but

the truth. It was suggested that the bullets might have been poisoned, but there seems to be little probability of this.

At the end of the fourth day two stitches were removed because of some wound irritation. Nutritive enemata and stimulants hypodermically had been administered, but now some liquid nourishment was cautiously given by mouth. Convalescence was believed to have begun. On Thursday, the sixth day, a piece of toast, some weak coffee, beef juice and a cup of chicken broth were given by mouth. The surgeons were confident that the gastric wounds had been securely sutured. There was nothing to indicate food would not be assimilated; indeed, food had been absorbed, and the patient's condition demanded nourishment. Then, like a bolt from the blue sky, came the tiding that the patient was fatigued, that there were evidences of toxemia. Many thought of perforation. Questions as to the propriety of allowing food by mouth were raised by some, as if small fragments of broth-soaked toast could tear asunder the careful stitching that had been done.

Dr. Charles D. Stockton was asked as a medical expert to see the weakening patient. The morning of the next, the seventh day, hope grew stronger, but towards evening fear assumed supremacy, and when night fell hope was abandoned, and the situation resolved itself into a watching and waiting for the inevitable. Early in the morning Dr. Edward Janeway, of New York, and Dr. W. W. Johnston, of Washington, were summoned, but nothing mortal brain could evolve, nor mortal hand do, was sufficient to stay the ebbing vital tide. As the last words of the dying President expressed it, "God's will, not ours, be done."

Few adverse criticisms concerning the treatment have been made. The country is convinced that nothing was left undone, and everything was done to save its leader, and that the accursed bullet, together with the weakened resistance of its victim, engendered by long and onerous public service, was the direct cause of death, and that this was destined to be so from the first. All the surgical skill and good judgment of the world's surgeons could have done no more than was done.

The following report of the autopsy silences all criticism. It was made on the day of death and signed by representatives of the government, the family and the profession.

REPORT OF AUTOPSY.

The bullet which struck over the breastbone did not pass through the skin, and did little harm. The other bullet passed through both walls of the stomach near its lower border. Both holes were found to be perfectly closed by the stitches, but the tissues around each hole had become gangrenous. After passing through the stomach, the bullet passed into the back walls of the abdomen, hitting and tearing the upper end of the kidney. This portion of the bullet track was also gangrenous, the gangrene involving the pancreas. The bullet has not yet been found. There was no sign of peritonitis or disease of other organs. The heart walls were very thin. There was no evidence of any attempt at repair on the part of nature, and death resulted from the gangrene which affected the stomach around the bullet wounds, as well as the tissues around the further

course of the bullet. Death was unavoidable by any surgical or medical treatment, and was the direct result of the bullet wound.

5. A Case of Peroneal Muscular Atrophy.
CHARLES GILBERT CHADDOCK.

2.—H. I. Hansell states that **atrophy of the optic nerve in diabetes** is either primary or secondary to retinitis. In the former the loss of visual acuity is rapidly progressive until it is complete. The field shows contraction, sometimes concentric, sometimes irregular. The ophthalmoscopic appearances are those usual to simple optic nerve atrophy. Lawford says the complication is extremely rare and the cases on record in which single optic nerve atrophy was present are few in number, and in several of them it is questionable, whether the optic nerve lesion should be considered the result of the glycosuria. "Of fifty cases with ocular symptoms, observed by Leber, there were fourteen, *i. e.*, twenty-eight per cent. with optic trouble." In two cases in which a post-mortem examination was made, a tumor was found pressing on the optic chiasm in one, and in the other there was no cerebral lesion, but there was distinct degeneration of the kidneys. Williamson says it is stated that occasionally the retinal changes are associated with primary optic nerve atrophy and he gives an illustration of such a case. He also says that it is exceedingly rare that a central lesion has given rise to an optic neuritis and glycosuria in the same patient. In the examination of 140 diabetic patients, Schmidt-Rimpler obtained evidence of retro-bulbar neuritis, not traceable to the abuse of alcohol or tobacco, in 34. In one case, distinct atrophy of the macular fibres of the optic nerve was found on microscopical examination. Wiesinger describes in detail a patient, 57 years old, with plastic iritis who had amblyopia; the ophthalmoscopic appearances were those of simple optic nerve atrophy without other limitation of the field than color scotoma; and another case with recurring iritis, senile cataract, glaucoma, and finally optic nerve atrophy of the left eye, all of which symptoms he traced to diabetes. THE DELETERIOUS RESULTS FOLLOWING OPERATIONS IN HYPOCHONDRIASIS, PERFORMED FOR THE SAKE OF MENTAL IMPRESSION.

By PROFESSOR A. PICK.

of Prague, Bohemia.

* Translated with Permission of the Author by Max R. Dielspiel.

The almost common-place statement that the progress of human knowledge takes place, figuratively speaking, not in a straight, but in a spiral and gradually ascending course, is also true of the science and practice of medicine; in the latter we see how from time to time views and methods of treatment return, which earliest observers have advanced and practiced with imperfect results; at any rate a new "phase" sometimes deceives us concerning the derivation of "new" ideas, and such a fallacy in itself justifies us in tracing the relationship and showing the invalidity of modernized views on the subject under consideration. In the following discussion I take occasion to consider such a phase of older psychiatry that has recently again been brought to my notice; not only because it appears to me to be justified, in itself, but also because it is qualified to throw light upon other pertinent facts.

During about the first third of the last century operations performed for their mental impressions occupied a prominent position in the therapy of hypochondriasis, and examples of such operations are still found in modern literature (Griesinger). These were principally cases which are now considered as hypochondriacal paranoia, and which are characterized by a delusion becoming developed and fixed in the patients, that they have a foreign body—an animal, in the affected area, the delusion being caused by abnormal organic sensations, and the accompanying imaginations; the operation, and the demonstration of the foreign body removed by the operation, were supposed to have a curative effect upon the patients, in that the changes of imagination produced by these procedures, gave rise to the disappearance of the hypochondriacal ideas.

This project, however, based upon an imperfect conception of psychological phenomena, was almost as a rule a source of disappointment; moreover, the effect of the operation was nearly always that the increase in the attention directed toward the symptoms, gave rise to their intensification, and caused not only stronger fixation of delusions already present to be developed, but the formation of new hypochondriacal ideas as well. It resulted, that such operations, even if they have not entirely disappeared from the list of alleged remedies against such an obstinate affection as hypochondriasis, at least became fewer, more recent literature showing but scattered instances of such interferences. Jolly (in Ziemssen's *Handbuch der Krankheiten des Nervensystems* Vol. 2 pag. 701, 2. Edition 1877,) reports the case of a paranoiac, who claimed that his wife had stuck quills into his head, into which physicians had frequently made incisions and shown him the

removed obstacles, but all of course without the hoped-for result.

Although such observations occur more rarely in literature at present, and although Jolly himself, in revising his chapter on "hypochondriasis" in Elstein's manual on internal medicine which has just appeared, ignores such operative methods, it nevertheless would be erroneous to conclude that these methods of treatment are entirely discarded by contemporary authors.

While it may no longer occur if for instance a patient should claim that he feels spiders in his stomach, that one of these operations would be performed and the spider subsequently shown to him, nevertheless almost similar procedures are not rarely employed at the present time, only that they are hidden, as it were, under a medical subterfuge. Boettiger (*Archiv für Psychiatric*, 31, pag. 397) reports the case of a woman who had contended that she was pregnant and who finally persuaded a physician to perform an operation, which probably consisted in a curettement of the uterus under chloroform anesthesia; in spite of the suggestion to her that after all that was possible had been removed, she must of necessity feel considerably relieved, abnormal sensations again occurred which were finally worked out by her into hypochondriacal delusions. For such reasons I consider it by all means apropos to show the useless and generally directly harmful consequences of such operations.

The most significant of my observations is that of a man now 39 years of age, a watchmaker by occupation, who has been visiting the clinic for several months, and whose psychosis, which has existed for several years, has been known to me from private consultation, since its inception. He himself always states the following: More than three years ago he awoke one night with an erection of the penis, and as he was not in the position to have intercourse with his wife, he masturbated; in order to quickly complete the act he had knocked the penis, which was still in a state of erection, against his thigh, and, according to the patient injured the organ. The patient makes various statements regarding the nature of the affection, at one time saying that he had "broken something," and at another time that he experienced a sensation as if there were two needles at the location of the alleged traumatism; he furthermore states that he is now ill, and could not work, being occupied all day with thoughts of the injury. He visited all the physicians he possibly could, and in spite of their assurances that nothing was the matter with him, he finally submitted to an "operation." As a result of this operation there is present a long whitish scar about 2 cm. in length extending from the root of the penis upward along the pubis, and but superficially involving the skin. The patient states the operation had been absolutely of no aid to him moreover he had become worse thereafter. He not only persisted in his statement as to the alleged injury to the penis, with which he was exclusively occupied during the first years of the psychosis, but now believes that all the pelvic organs are involved; he thinks that his kidneys are affected, that there is water in his abdomen, causing distortion, that his liver had become black, etc., etc.; the whole day he is occupied with the condition of his pelvic organs, and even when he does not suspect that he is being watched, he presses his hand against the genitalia, slinking about with his body distorted, as if in pain. He has entirely neglected his business, and on account of various irrational acts his detention at the institution became necessary; he has repeatedly expended large sums with frequenters of saloons, stating that he would soon die anyhow. His frame of mind is continually depressed, and it was only possible to keep him occupied for a brief period. The somatic examination yields absolutely no tenable point upon which to base the hypochondriacal sensation; no material nervous disturbances of motion or sensation can be demonstrated.

Without entering any further into the clinical diagnosis, it will suffice if I call attention to the fact that we obviously had to deal with one of those cases of hypochondriasis which from the very beginning ran its course according to the acute paranoic type. And I particularly desire to emphasize, that the operation performed for its mental impression not only was futile, but just like any other local procedure, was bound to lead to an intensification of the disease because the increased attention directed to the *locus morbi* caused also an intensification and increased development of abnormal sensations. Even old Romberg has called attention that one of the principal indications in the treatment of hypochondriasis is "the diversion of the attention from the sensitive area", and therefore the procedure under discussion not only does not meet with the indications of Romberg, but directly contraindicates them.

Of course, in order to oppose the argument just advanced, it may be contended that in the cases just alluded to, a simple hypochondriasis did not exist, but one of the paranoic variety; notwithstanding it is just these cases mentioned in literature, which very easily mislead one to perform operations for mental impressions. Consideration of the subject will lead to the universally accepted conclusion (but one whose consequences are yet too little considered) that also in simple hypochondriasis, even mild procedures, unless they are stringently indicated by any existing local affections, produce effects contrary to those expected. I would like to report here another case as showing that even in cases where hypochondriacal delusions are associated with local affections, great care must be taken and due weight be given in considering whether harm would not be done even by the otherwise indicated operation.

In the year 1897, a proprietor of a tavern, 34 years of age, was brought to the clinic with the following medical history: About four weeks ago the patient was brought to a physician on account of a marked depression of spirits. The physician upon careful examination found a congenital phimosis; the patient was visibly gratified that the cause of his depression was found, and without making any mention of it himself, accepted the proposed operation, which was subsequently performed. Immediately after the operation the patient was joyful, worked diligently, and seemed like a changed individual. But soon a new idea in the patient became formed, namely that the foreskin must glide over the whole penis in order for the operation to be successful, and in consequence within fourteen days the patient again became timid, began to fear everybody, and became possessed of suicidal ideas.

The patient, upon whom, with the exception of the remains of the phimosis and a mild balanitis, nothing abnormal could be demonstrated, gives the following personal history: Whenever he wanted to marry he became possessed of the idea that his foreskin was not the same as others, and therefore he could not marry; also that he could not urinate on account of the overgrowth of the foreskin, and this year, for the first time, he sought medical aid, feeling thoroughly satisfied after the small operation had been performed. But soon again he believed that he could not marry, thinking that he had another disease, and finally he became possessed of fear; he claimed that people knew all about his ailments, that they had cracked whips at him, and had whistled, and furthermore he had heard various voices resembling those of animals, it appearing to him as if people were laughing at him (there is no history of true hallucinations). All this had excited him considerably, especially because he did not know what it all signified, and therefore he thought of suicide. Sometime thereafter, the patient's frame of mind improved, he

slept better, his appetite also improved, his ideas became clearer, and finally he stated that all his ailments had been due to a mania of persecution which he had had. The patient was then taken away by his relatives, in an improved condition.

If we analyze this case it will be seen that the intensification of a visible defect, as represented by the delusion regarding the phimosis, is that condition which recently has been designated by Wernicke as "the over estimated idea" and it will furthermore be plainly evident how this idea was not removed by the operation, but increased to develop in the sense of a simple paranoia, which apparently, as far as our own observations are concerned, ran an abortive course.

The following case, although clinically different, no operation having been performed, resembles the previous one, in as far as the insinuation of the necessity of an operation had something to do with the fixation of the delusion.

In the year 1899 a woman, 37 years of age, who at that time was nursing her 3 months old, and tenth child, was admitted to the clinic. Upon admission she states that about one year ago when an ulcerated finger was lanced, she suddenly felt a splitting pain in her head, followed by inability to move the whole arm; this paralysis, which was accompanied by anesthesia of the whole member, lasted for three months, and occurred without any unconsciousness on the part of the patient. While the history was being taken the patient also spoke of the "little frog" which she had in her mouth, similar to the one she stated her son had; a physician, according to her statement, had cut the one of her son and told him that the whole family was similarly afflicted; since then she had felt the frog in her body, into some aperture of which it had gained entrance; she could feel how the animal sucked up the blood in her brain, how it blew itself up in her intestines, causing her abdomen to become quite distended. When this first began, she looked into her mouth and had seen the little frog under her tongue. She therefore visited various physicians, one of whom had attempted to quiet her regarding the frog, but another had told her that an operation would have to be performed, and since then she has had no peace. Her frame of mind in spite of encouragement and explanation is markedly lowered, and she is constantly occupied with the frog, and the fate which she believes is in store for her. Since a few days, however, her mood has changed, she now declaring that she does not wish to have anything to do with the ranula (which is really the local cause of her trouble) and states that she has now fully recovered as she had "bitten away the frog" during the night. Her wish to look after the children was gratified by her husband, in spite of advice to the contrary, notwithstanding the change in her condition.

In the absence of all other symptoms, the possibility of hysteria was thought of, which also seemed to be suggested by the self-described "attack" of the patient; but on the other hand examination showed nothing to substantiate the suspicion, and therefore the case remained somewhat obscure, until later on the patient again presented herself with at first a doubtful, and later a well marked case of progressive paralysis, euphoria and delusions of grandeur.

In conclusion I will report a pertinent observation from the clinic which is qualified to show the futility of repeated examinations in the cases under discussion.

A woman, sixty years of age, when questioned regarding her "ear disease" stated the following: "In July, as she was sitting in the open, an earwig had crawled into her ear. Since then she has pains in the head, which increased since a physician had told her that nothing could be done for her. When questioned closer concerning her malady, she stated that it was fearful and that she experienced the sensation as if young birds were in her head. At first

there was an itching sensation in one ear, later in both ears; she had consulted several physicians who had syringed her ears and assured her that there were no foreign bodies therein, but apparently they did not find anything "because they did not possess the necessary instruments;" another physician had injected alcohol into her ear in order to force the worm to crawl out, and then told her that it had been removed; improvement set in for a few hours but soon again she felt that there was a "breathing" in her head. She then presented herself to the ear clinic whence she was referred to the psychiatric clinic. In addition the daughter of the patient stated that soon after the onset of the affection the patient had complained that the earwig was growing, and had borne young ones, the latter having now crawled over to the other side of the head; she also contended that occasionally at night she felt as if a small pouch was growing out of her head; if someone would only take the worm out of her head; she herself had attempted to cause the worm to crawl out by injections into her ear; she thinks of nothing else but that her mind has been weakened; appetite and sleep have been profoundly affected.

This case also does not require any further explanation for it substantiates what has been said about the deleterious results in such cases, of all operations performed for their mental impressions.

CONCERNING THE TREATMENT OF THE APPARENTLY UNAFFECTED OR AT MOST BUT SLIGHTLY INVOLVED EYE IN CASES OF GLAUCOMA.

By G. E. de SCHWEINITZ, A. M., M. D.,

of Philadelphia.

This paper deals only with cases of *primary* glaucoma when they appear as (1) acute glaucoma; (2) subacute or chronic congestive glaucoma ("glaucoma irratif," chronic inflammatory glaucoma); (3) chronic non-inflammatory glaucoma (usually known as simple chronic glaucoma); (4) absolute glaucoma. These varieties may be described as follows:

Acute glaucoma, although a disease of sudden onset, may give warnings for weeks and even months prior to the attack. These warnings are alterations in the amplitude of accommodation; temporary obscurations of sight, iridescent vision, that is, the phenomenon of rainbows around artificial lights; and periods of increased intraocular tension. The attack itself is characterized by severe pain, sudden almost complete loss of vision, dilatation and immobility of the pupil, shallowness of the anterior chamber, steaminess of the cornea and great increase in intraocular tension.

Chronic congestive glaucoma may have the same prodromal signs which have just been enumerated, but these are repeated and progress until they, with several added ones, become the salient symptoms of the disease: Steamy cornea, shallow anterior chamber, semi-dilated pupil, degenerating iris, cupping of the optic disc, pulsation of the retinal vessels, and contraction of the visual field, most often on its nasal or supero-nasal approach. Exacerbations are common, and then chronic congestive glaucoma resembles acute glaucoma, although it should be regarded as a different clinical manifestation.

Chronic non-inflammatory glaucoma, ordinarily known as *simple chronic glaucoma*, presents no active symptoms. Instead there are progressive failure of vision, particularly of the field of vision; exca-

vation of the optic disc; crowding of the vessels to the nasal side; halo around the nerve-head, and increased *intraocular tension*, which may not be constantly present. It is difficult to fix the date of onset in this variety because of the absence of the pronounced prodromal symptoms which may precede the other types of the disease.

It is important, as De Wecker insists in his admirable *Rapport sur la Valeur de l'Iridectomie dans le Glaucoma*, presented to the *Société française d'Ophthalmologie*, in May, 1901, to separate from each other these three great clinical types of glaucoma if one wishes to obtain the best results from therapeutic measures. Furthermore, it seems inadvisable, at least in the present state of our knowledge, to exclude simple glaucoma from the catalogue of the glaucomas, but it should be carefully distinguished from progressive optic nerve atrophy with excavation and other types of progressive optic nerve disease unassociated with increased intraocular tension.¹ The chronic congestive variety of glaucoma sometimes resembles simple chronic glaucoma and *vice versa*. If, as De Wecker has pointed out, in the affected eye corneal involvement is made evident by nebulous vision, halos, etc., or, in other words, by irritative attacks, the case ceases to be one of simple glaucoma, and is to be grouped with the chronic congestive types.

All of these varieties may pass into the stage which we ordinarily know by the name *absolute glaucoma*, with its characteristic symptoms of fixed and dilated pupil, discolored iris, greenish reflex from the lens, obliterated anterior chamber and hazy cornea.

From the times of Von Graefe to the present day experienced ophthalmic surgeons have held that some form of surgical intervention most frequently gives the best and most permanent results in the treatment of glaucoma, and that the more nearly such intervention approaches the onset of the disease, the more likely is the ultimate effect to be a good one.

The reasons for promptness in surgical interference are not hard to find. As Rochon-Duvignaud tersely puts it: the excretory apparatus of the eye (iritic angle) is intact at the time of the first attack of glaucoma, but it is obliterated at a more advanced period of the affection. Iridectomy will be efficacious if performed *before the root of the iris is welded to the cornea*; otherwise not.

The *bilateral character of glaucoma* is well known and has been commented upon by Von Graefe and all succeeding writers. All cases of acute primary glaucoma which have come under my own care during the last fifteen years, except two which followed the instillation of a mydriatic,² have sooner or later been bilateral, the shortest interval being about six hours and the longest two years and ten months; that is to say, all that I have been able to trace. The same is true of cases of chronic congestive glaucoma. Of chronic non-inflammatory glaucoma we may say, with Von Graefe, "glaucoma

¹ Czermak (quoted by De Wecker, loc. cit.) typifies a school which holds to an entirely different definition of chronic simple glaucoma, inasmuch as he admits in this class only those cases in which he has never been able to establish an increase in the tension of the ocular globe.

² One of these cases shows prodromal signs in the other eye.

* A Paper presented to the American Ophthalmological Society, July 1901.

simplex affects almost without exception both eyes successively;" or with E. T. Drake-Brockman, "persons suffering from chronic glaucoma are usually attacked in both eyes simultaneously, or at very brief intervals of time between the two eyes"; or with Nettleship, "in something like two-thirds the disease is sooner or later symmetrical;" or with Priestley Smith, "in the large majority of cases primary glaucoma is a bilateral affection." I need not burden the pages of this paper with further quotations illustrating this point.

Occasionally the interval of time between the beginning of the disease in one eye and its development in the second is very long. Thus, Mr. Nettleship¹ referring to chronic glaucoma, says: "In twenty-six cases at least a year was known to have elapsed since the disease in the first eye; in thirteen of these twenty-six five years or more had elapsed without the second eye being attacked." But immunity for five years does not confer complete immunity, and it is impossible to state that any specified interval insures to the second eye entire freedom from risk. Ten-year intervals have been reported by Schweigger and other observers. The most notable instance of delay in the appearance of glaucoma in the second eye, viz., twenty years, has been contributed by Mr. Priestley Smith.² These cases, however, are the exception. The bilateral character of glaucoma, or a comparatively short interval before the second eye is affected, is the rule.

To introduce the subject, and I hope to stimulate discussion, I wish to propound certain questions:

1. *What shall be done with the apparently sound eye after the first eye has been operated upon for acute glaucoma?*

It is a well known fact that iridectomy upon one eye for acute glaucoma is frequently followed by a speedy outbreak of the same disease in the opposite eye. Therefore a good rule and one usually followed, is to keep the non affected eye under the influence of a myotic until the eye upon which the operation has been performed is entirely healed and free from irritation. A case of this character is the following:

CASE 1.—A woman, aged 30 +, came to the Jefferson Medical College Hospital with typical acute glaucoma of the left eye which had existed for five days. Iridectomy was immediately performed under general anesthesia; no reaction; wound closed in twelve hours. Forty-five hours later an attack of acute glaucoma occurred in the right eye, which was controlled by eserine. There was a repetition of this attack one week later, when a broad peripheral iridectomy was performed, healing without reaction; ultimate vision in each eye 6/6.

Outbreaks of glaucoma during the first two weeks after an iridectomy has been performed upon one eye are especially referred to by Von Graefe,³ who noted that they were very apt to happen (in thirty per cent. of his cases) when the operation had been made on an eye with primary acute glaucoma during the period of high-grade inflammation, especially if it previously had exhibited prodromal signs of glaucoma. A good example of this character has been recorded recently by Dr. Risley.⁴

The cases described by Von Graefe are typified by the following instance from my practice:

CASE 2. On September 3, 1900, a woman, aged 70, came with typical acute glaucoma of the right eye, vision being reduced to shadows. In the left eye were peripheral lenticular opacities, a slightly congested disc containing no cup, and full veins depressed and crossed by arteries undergoing endarterial changes; tension and field normal; refraction hypermetropic, 5D. The right eye was iridectomized on September 7; no complication except much hemorrhage in anterior chamber, which was slow in absorbing; complete relief of pain and reduction of tension to normal. On the twenty-eighth of September, that is, eleven days after the iridectomy, while the patient was quietly sitting in her own room, she began to notice at four o'clock in the afternoon, obscuration, halo-vision, etc. before O. S.; tension + 2; cornea deeply hazy. A typical attack of acute glaucoma was cut short with pilocarpine and large doses of salicylate of sodium. Iridectomy was proposed the next morning, but positively declined. The patient continued to use pilocarpine in that eye until the day of her death, eight or ten months later.

Sometimes the interval between the attacks is very long. A case in point is the following:

CASE III. A woman, aged 50, with constitutional syphilis, and who had suffered from plastic iritis, which, however, had entirely disappeared, was attacked in the left eye with typical acute glaucoma on October 10th, 1895. An iridectomy was at once performed; the wound healed with entirely satisfactory results and vision equalled 6/9, which degree has remained until the present day. The right eye was apparently healthy, only a few pigment flecks on the lens capsule; refraction hyperopic, 2 D. On the 21st of December, 1898, the right eye was iridectomized for an attack of acute glaucoma which had lasted twenty-four hours and had appeared with the usual prodromes; normal healing; ultimate vision 6/6. The interval between the two attacks was two years and ten months.

It is not germane to the present inquiry to discuss the causes which contribute to the second attack: predisposition, dilatation of the pupil under a covering bandage, shock, worry, and nervous apprehension, all have been given a rôle in this respect. Doubtless two are potent, viz.: apprehension in a predisposed subject.⁵

Are there any signs by which one may reasonably infer that the apparently sound eye will suffer an acute glaucomatous attack like its fellow eye, within a comparatively short time? The following have been suggested:

(a) Shallowness of the anterior chamber and beginning opacity in the lens with swelling and a high degree of hypermetropia, and smallness of the corneal diameter.

(b) The mydriatic test suggested by Edward Jackson,¹ G. C. Harlan,² and W. A. Brailey.³ This consists of the instillation of a solution of homatropine into an eye which is under suspicion, and noting whether it produces any rise in intraocular tension, or pulsation of the blood vessels of the fundus.

(c) The palpation test; that is, an observation is

¹ Ophthalmic Record, March, 1901.

² The disposition of the first patient whose history is recorded (Case 1) entirely changed after the second iridectomy. Prior to this she was apprehensive to the point of nervous irritability; her expression gave the impression which is best described by the word "hunted." Asked in regard to the change in her mental attitude, she replied: "Ah, you see the terror is gone." This anecdote is recorded because it well illustrates the potency of apprehension; De Wecker makes similar references.

³ Am. Jour. Med. Sciences, April, 1898; also International Clinics, Vol. I., Eleventh Series.

⁴ Ophthalmic Record, January, 1898.

made whether finger-pressure on the globe so slight that in a healthy eye it does not cause pulsation of the bloodvessels of the fundus, does cause them to pulsate in the eye under suspicion.⁴

(d) The history of prodromal glaucomatous phenomena.

If these tests are positive, the correct answer to the question originally propounded would seem to be: *An iridectomy should be performed upon this eye as soon as the anterior chamber is restored upon the opposite side; that is to say, as soon as the wound has closed; in the meantime the eye should be kept under the influence of a myotic.*

Doubtless many will at once say, "Certainly, who teaches otherwise?" I do not know that any one teaches otherwise, but I also doubt if in any well-known modern textbook this advice is given in so many words, although now and then the statements are fairly positive. Thus Fuchs¹ says: "In inflammatory glaucoma an operation should be performed in the prodromal stage, provided the patient will consent. If the operation is deferred until the inflammatory attack is developed, the surgeon cannot foretell how severe it will be, and, moreover, he operates under less favorable conditions." I am inclined to think we may advance even beyond this position under the circumstances which I have detailed, especially if the patient is to pass from under expert observation, and be placed under conditions not favorable for obtaining competent advice.

II. *What shall be done with the apparently sound eye after the first eye has been operated upon for chronic congestive glaucoma?*

The situation can best be described by detailing the history of a patient whom I examined by the courtesy of Dr. Myles Standish, of Boston, whose notes, somewhat condensed, I am permitted to quote:

CASE IV. A man, aged 42, was examined first in January, 1896 and had a compound hypermetropic astigmatism of the right eye and a mixed astigmatism of the left eye corrected, vision rising to normal. He complained of a rainbow ring around artificial lights at times, the phenomenon being present only before the right eye. There was absolutely no other sign of increased intraocular tension. He was forbidden to do close work for prolonged periods at a time (he was an architect by profession), and was given a solution of eserine with instructions to use it in case the signs of acute glaucoma appeared. In the fall of the same year his eyes were again examined: the rainbows had increased in frequency and sometimes persisted for several days. Vision was still entirely normal on clear days. The central depression of the nerve-head occupied about two-thirds of its centre and there was venous pulsation; the tension was noted as very doubtfully increased. The field of vision was absolutely normal. Six months later the condition was still unchanged, that is to say, when the examination was made. In June, 1898. He was not again seen until February, 1901, when the vision of the right eye was .2 and the tension +1; there was loss of nasal-field, and the nerve-head was typically cupped. Before the left eye, which previously had exhibited absolutely no sign of trouble, rainbows had begun to appear, but vision and field of vision were normal; tension was doubtfully increased.

Three months later his visual fields appeared as in the diagrams. (Figs. I and II).

⁴ It is needless to point out how difficult it is to apply this test with accuracy.

⁵ Some surgeons would prefer sclerotomy.

FIGURE 1.—Almost complete loss of nasal and lower field semi-circular scotoma. Case I.

This is a case of chronic congestive glaucoma, although there never were any very violent manifestations. It is a type of the cases to which De Wecker refers so eloquently in his report and which

FIGURE 2.—Beginning contraction of field, particularly on nasal approach; dotted line represents red field. Case I.

nearly approach in their clinical history simple glaucoma, and therefore may be debarred from the most desirable treatment, or, in other words, there may be unnecessary delay in surgical intervention. Had it been possible for the patient whose history has just been detailed to be under constant observation, or had he permitted himself to be examined by his ophthalmic surgeon at suitable intervals, the decided change from the prodromal to the more fully developed glaucomatous stage would have been prevented by iridectomy. But this is the very point of the whole matter. How soon dare we interfere in these cases, and if we interfere surgically, where may we point for authority for such early surgical interference? In such a case iridectomy would seem to be indicated as soon as the rainbow vision was certainly associated with attacks of increased intraocular tension. It illustrates further, as has so often been noted before, that even the most intelligent patients cannot be trusted to report at suitable times and in season; *an eserine existence is not a safe one.* Now, of course, a successful iridectomy on the right eye should be followed by an iridectomy on the left eye before the vision fails, and *while the iritic angle is intact.* This plan has, I believe, been pursued with satisfaction to surgeon and patient.

¹ *Lehrbuch der Augenheilkunde*, Achte Auflage, Wien, 1900, p. 432.

Doubtless all of us remember Laqueur's article on "The Prodromal Stage of Glaucoma,"¹ with its accurate description of the visual obscurations, the colored rings around lights, the nebulous cornea, and the increased intraocular tension, and perhaps we also remember his recommendation that at this period the treatment should consist of eserine, careful attention to the patient's general condition, particularly his diet, but that if after a time any anatomical change in the eyeground, any excavation of the optic nerve, or any obscuration of any portion of the visual field, or any sign of the same disease in the opposite eye should appear, then an iridectomy should at once be performed. He refers to the brilliant results which Von Graefe obtained with iridectomy in this very prodromal stage, and says that his own experience can confirm this, and yet he hesitates. Why should one wait for the excavation, or for a permanent obscuration of a part of the visual field, when a clinical history definitely shows that there have been periods of rainbow and nebulous vision and increased intraocular tension, and particularly when it can be proven that these were dissipated by the use of a myotic. Why should one wait until the damage is done? Would it not be better to anticipate both the agglutination of the root of the iris to the cornea in a firm adhesion, and the destruction either of areas of ganglion cells of the retina, or of the optic nerve fibres, by making what E. Treacher Collins¹ has termed a *preventive iridectomy*, which he thinks under certain circumstances is justifiable? Perhaps you may say, "Who acts otherwise," and yet authority for such a surgical procedure is hard to find; I have already quoted Fuch's opinion.

III. *What shall be done with the apparently sound eye after the first eye has been operated upon for chronic simple glaucoma?*

It is confessedly more difficult to give an answer but also less frequently necessary, because so many cases of chronic non-inflammatory glaucoma are bilateral, almost from the start.

If this type of chronic glaucoma is bilateral, operation upon the more affected eye, followed as soon as it is safe by iridectomy (or sclerotomy, or a combination of both) upon the other eye, is a common surgical procedure and gives the patient the best chance.¹

Frequently, however, one eye is pronouncedly glaucomatous, and the other eye, although presenting the ophthalmoscopic appearances of glaucoma of this type, retains perfectly normal central and peripheral vision, and the patient would be greatly surprised if operative interference on this eye were proposed. A case in illustration is the following:

CASE V. A man, aged 70, of typical gouty antecedents and with many gouty manifestations, and who had had many attacks of influenza, came with typical chronic glaucoma of the right eye. Vision included large letters seen only eccentrically. The field of vision is illustrated in the diagram (Fig. III). The nerve-head was typically cupped;

FIGURE 3.—Almost complete loss of nasal half of visual field, with scotoma encroaching on central area. Case 7.

the vessels were pushed to the nasal side; there was slight increase in intraocular tension. The vision of the left eye was normal after the correction of its hypermetropic refraction, +1.50 D; the media were clear; the disc was typically cupped; there was no positive increase of tension; the peripheral field was perfectly normal. A more careful field taken a few days later still showed that the periphery was nearly normal, but that a scotoma existed in the position marked on the diagram beginning at the blind spot and passing upward and inward. (Fig. IV). Iridectomy

FIGURE 4.—Just beginning contraction of nasal field; scotoma extending from blind spot in semi-circular manner upward and inward. Case 5.

tomy on the right side was proposed and declined. The treatment consisted of eserine, strychnia and nitro-glycerine. Eighteen months later, although central vision in the left eye is perfectly normal, the scotoma has progressed and became ring-shaped. (Fig. V). The right eye remains

FIGURE 5.—Visual field of Case 5, eighteen months after Figure 4 was drawn; greater contraction; scotoma now ring-shaped.

as before, tension, if anything, a little greater. Vision only hand movements. Operation is still declined.

This is a type of many cases in which, in spite

¹ Royal London Ophthalmic Hospital Reports, XIII., 1890-93, p. 166.

¹ I am aware of the fact that Mr. Nettleship doubts the propriety of operating upon the poorer eye first, but begins at once upon the better or less affected eye.

of the normal vision and practically normal peripheral field, it would seem proper to urge iridectomy, or, at least, some form of operative interference; the evidence of what will happen is afforded by the other eye.

Less frequently this type of the disease is truly monolateral, or as nearly monolateral as these cases ever are. Are there any signs by which one may reasonably infer that the apparently sound eye will pass, gradually to be sure, into a condition resembling the one upon the opposite side. The following have been suggested:

(a) Ophthalmoscopic evidence furnished by the formation of a cup beginning to be pathological on the temporal side.

(b) Periods of increased intraocular tension detected with the educated finger tips, placed, as Coccius and Schweigger advise, upon the sclera itself. Such examinations should be made at different hours on the same day and repeated in the evening, as it is well known that in this disease increased intraocular tension is not constantly present and may be absent for hours and even days at a time. There is no reason why we should not place the patient under circumstances where expert examination can be made very frequently, no reason, for example, why he should not be watched exactly as the general surgeon causes cases suspected of Jacksonian epilepsy to be watched for days at a time until he establishes or does not establish localizing symptoms.

(c) Alterations in the visual field. In typical cases restriction begins on the nasal side and contraction of the color field-corresponds with that of white. That this rule meets with exceptions, and perhaps frequent ones, I am sure.¹ It cannot then be utilized alone as a safe guide of action.²

Again, the visual field might be contracted for one examiner and uncontracted for another, as there is perhaps no examination in ophthalmology which is surrounded by so many possibilities for inaccuracy. But if on successive days, under the same circumstances, controlled, if necessary, by separate examiners, and especially if the test-objects include squares of gray paper (Ward Holden's tests, for example), the visual field is found contracted, it may be on the nasal side or it may be concentrically, it is fair to assume a beginning pathological change and to act accordingly.¹

But it is not sufficient to trust to the periphery of the visual field for information. I am convinced that the study of scotomas in connection with chronic glaucoma furnishes a prognostic guide. There is no difficulty in finding them, either by the method suggested by Bjerrum, who uses a small test-object at a much greater distance than that or-

dinarily employed, or by ordinary perimetric methods, when care is taken to investigate each meridian and suitable test-objects are employed under varying degrees of illumination. Doubtless, as Bjerrum has pointed out, these scotomas are the result of the destruction of the fibres of the papilla at the margin or sides of the excavation, but sometimes they are to be accounted for by alterations in the inner retinal layers. These scotomas are topographically different from those which occur in simple atrophy, and may be utilized as a differential test between the two conditions, as Bjerrum has already suggested.¹

As I have pointed out elsewhere,² scotomas are often the forerunners of subsequent defects in the peripheral visual field. The following diagrams illustrate this, and are taken from the paper already

FIGURE 6.—Chronic glaucoma, female, act. 55. Visual field of right eye, showing the mechanism of the loss of the lower and inner portion of the field with preceding development of scotoma which gradually extends.

FIGURE 7.—Later stage of Figure 6. Visual field completely dark.

referred to. (Figs. VI, VII.) Therefore, I would warn against the conclusion that the field of vision is normal because its periphery has its full extent. No field is mapped until each meridian has been examined from fixation point to periphery when dealing with cases of chronic glaucoma.

(d) De Wecker's sclerotomy test. This surgeon has suggested the performance of anterior sclero-

¹ *Annals of Ophthalmology*, VIII., October, 1899.

² I am aware that Mr. F. R. Cross (*The Treatment of Chronic Glaucoma*, British Medical Association, August, 1900), referring to the field of vision in chronic glaucoma, states that he is satisfied "that diminished vision on the nasal side (or in the upper or lower quadrant of the nasal side) is the most important evidence that we can obtain for the early detection of chronic simple glaucoma, while the retention of vision in the temporal and infero-temporal portion of the field is equally characteristic as the disease progresses."

¹ Even De Wecker is willing to use eserine as long as vision and the visual field remain normal, but at the very first sign of depreciation or contraction, he operates. This necessitates a constant and faithful attendance of the patient, difficult to secure.

¹ It will be remembered that Bjerrum has frequently detected central or paracentral scotomas in chronic glaucoma and believes that they are peculiar in that they spread over the periphery in all directions, sometimes more in one direction than in another, except outward, where they never pass beyond the blind spot. In other words, the defective area wherever situated is in direct continuity with the blind spot. I have not always found this direct continuity, but the scotomas are certainly very commonly present.

² *Annals of Ophthalmology*, VIII., No. 4, October, 1899.

tomy in doubtful cases—an operation which he thinks is harmless. If the symptoms are ameliorated, especially if the visual field enlarges, the suspicion is confirmed, and iridectomy may be performed.

Absolute glaucoma may be a unilateral disease. Generally if one eye is blind from glaucoma of this type, the question when an operation shall be performed upon the opposite eye is answered with the statement: not until there are some manifestations of glaucoma. On this point Finkala¹ is very emphatic, being one of the few writers who seems to have the courage to state his convictions exactly. He says: "In case the glaucoma of the first eye is already absolute, one should perform an iridectomy upon the second eye before the outbreak of the disease, at least, when the suspicion that there will be an outbreak exists." He does not forget to discuss in this connection the chances of failure, and whether an iridectomy is a positive preventive of future attacks of glaucoma, reaching the conclusion that the former are slight and the latter, while not absolutely certain, furnishes the patient with the best protection. The patient must submit to the risk which all operations entail of inflammatory and infective processes, the danger of the development of cataract, especially if cataract has already begun to develop, the temporary disturbance of vision caused by the changing from a circular pupil to a key-hole-shaped aperture, the astigmatism, which even the best placed iridectomy temporarily produces, and the danger that the operation may be followed by malignant glaucoma. These chances must be taken because apparently the risk is greater without than with the surgical interference, and taking all things into consideration, it seems probable, as De Wecker has so forcibly pointed out in his recent report, that surgical interference is, even at the present time, too frequently delayed rather than too frequently recommended. What is the best surgical procedure is not part of the present discussion. Personally I have expressed, and am glad to do so again, my preference for iridectomy. Others think differently. We have not yet sufficiently far advanced in our knowledge of sympathectomy to give it its proper place among surgical procedures.

I would make the following recommendations subject to alteration suggested by the discussion, which I trust will follow:

(1) In cases of acute glaucoma the apparently unaffected eye should be operated upon as soon as the anterior chamber is restored in the opposite eye: that is to say, as soon as the wound is closed, provided the history of the case or an examination of the eye furnishes indications already described that it is likely to suffer a glaucomatous attack like its fellow, especially if the patient is so situated that he or she will pass from observation and from the resources of expert examination.

(2) In cases of chronic congestive glaucoma the same line of advice applies, and the operation is to be urged if clear information can be obtained that the apparently unaffected eye has suffered attacks

of nebulous or iridescent vision, associated with increased intraocular tension.

(3) In cases of chronic simple glaucoma, if any periods, however, temporary, of increased intraocular tension can be demonstrated according to the methods already suggested, operation should be performed even if central and peripheral vision are perfectly intact. Even when these are normal, careful perimetric examination may reveal a scotoma of the character already described; if so, operation should not be postponed.

(4) In cases of absolute glaucoma the same line of advice expressed under No. 1 and 2 is applicable.

AN IMPROVED LANTERN FOR DETECTING COLOR-BLINDNESS, TO SUPPLEMENT THE DEFICIENCIES OF THE WOOL TESTS.

By WILLIAM THOMSON, M. D.,

of Philadelphia.

Emeritus Professor Ophthalmology, Jefferson Medical College, Ophthalmic Surgeon Penna. of R. R.

And ARCHIBALD G. THOMSON, M. D.,

of Philadelphia.

Ophthalmic Surgeon to the Childrens Hospital, Assistant Ophthalmic Surgeon to Wills Hospital and to the Orthopedic Hospital and Infirmary for Nervous Diseases, Assistant Ophthalmic Surgeon, Penna. R. R.

The present model is a more simple form of the one described a year ago in the last edition of Nettleship's book on Diseases of the Eye, and exhibited at the meeting of the American Ophthalmological Society, in Washington.

The lamp chimney and two discs are unchanged in form. Instead of ten holes there are now but seven, and the English measure is used in place of the French. The holes are one-half inch, except the small opening one-twelfth of an inch, which is equal in size to an angle of one minute at XX feet, and are

1. Berliner klin. Wochenschrift, 29, 1891, p. 1248.

2. De Wecker prefers sclerotomy followed by iridectomy.

*Read before the American Ophthalmological Society at its Meeting in July 1901.

to be viewed from the standard distance of twenty feet.

The lower disc contains the red, white, plain and ground, green, and blue glasses, similar to those used in railroad signals. The upper disc is for a "cross examination," and has white, ground white, the three "confusion colors," viz., London smoke, pink, and blue-green, which appear white to the ordinary color blind, and cobalt which to him appears and is called blue, having much red in it to the normal eye.

The letters of the alphabet designate the upper holes, and the figures the lower ones, when an accurate record is needed.

The examination is made in a dark room, the chimney being placed on its lamp, on an Argand burner, a spring candlestick, or over an electric light. The small opening may be taken as the standard of color perception at twenty feet, and the large one would be therefore six times in size. The color-blind make gross mistakes and can have their defects briefly stated on a record or blank by the examiner, using the letters and figures for this purpose.

A lantern of some kind has long been in use, that of Prof. Donders having been employed in all my examinations for years past. This one is of great value and should be used in connection with all of the wool tests, hereafter by not only the ophthalmic surgeon but by all lay examiners.

The uncertainties of Holmgren's generally-used test wools are pointed out by Eldredge-Green in the London Lancet for April 13th, in a paper which should be consulted, and which calls attention to the necessity of using transmitted light in lanterns. Of Holmgren's test he says: "If there be at the present time any specialist who is in doubt about its efficacy I shall be only too pleased to give him an opportunity of examining a case which has passed the test even under the most rigid and careful examination."

There are doubtful cases that all have encountered when using wools alone, and I am led to report the details of several of these.

I was aided in the first case by a young ophthalmic surgeon who suffers from *green-red* blindness, the form of color defect which I have found the most difficult to detect by the wool test of Holmgren and its varieties. Two years ago this young man had spent much time in trying Holmgren's test, but he always made an average of five failures. With the Color Stick he promptly selects the reds and the pinks, and half of the greens, making mistakes only in the group of light greens, which, with their confusion colors he sees as yellowish-brown. With the New Wool Test arranged for these difficult cases, the red colors being left out entirely, he does not select any blues with the rose or pinks, but reveals his real defect by confusing them with the greens. He so nearly passes the wool test that it is seen why practical examiners say that the Holmgren test does not succeed except in the hands of ophthalmic experts, and cannot be used by a lay examiner. The secret of his difficulty is revealed by the use of the spectroscope. Like all color-blind, the spectrum of this green blind man presents to him but two colors, yellow and blue. This coincides with the usual spectrum of the red blind man, whose spectrum is shortened at the red end. To show that there is a red perception in this case, a violet color screen, composed of red and blue, was placed in front of the spectroscope, when he lost all of the yellow and green part, but clearly saw the red end. A red screen also cut off his entire spectrum except the red portion, as it does in persons of normal color percep-

tion. This seems to show that he is dichromic, and partially color-blind, having the red and blue sensations only, but lacking the green. That he sees red objects is proved also by his having the acquired red blindness when looking at red objects through a peacock-green glass, a defect which is also induced in a normal eye. When tested with wools he sees the reds too well to fail in selecting them, as he also does the red in the pinks, for he never matches them with blue. He does not fail to see changes in the fundus oculi, nor in pictures of it—nor does he ever confound red with black ink, as the *red-green* blind may do. He seems able to distinguish the diseases that cause changes of color in the eyes of patients. He classified the wools of a full set of Holmgren placing the various colors together fairly well, making mistakes mainly with the greens which for him appeared as gray. He is therefore classed as a *green-red* color-blind. Attention is called to his selections preserved from the skeins with their names, on this card of bristol board.

Next, an engine-man from a railroad was seen soon after, whose symptoms were so similar as to need no further description. He had been examined by a doctor employed by his road, and found not defective. By another doctor he was considered as partly color-blind. He had been so carefully trained by his two daughters in the wool tests that he felt sure he would pass my examination. With the stick he made no mistakes with the red or rose skeins. He said a large imitation strawberry in my box, 3 by 2 inches, with red flannel body and yellow-green calyx, looked like a pear. When confronted with my lantern, however, the ophthalmic scholar, and the trained veteran engine-man were both helpless, and failed on every test by transmitted light. Red was called green or white; green was called red or white; the blue-green was called white or blue; the pink, gray; and the cobalts, blue. Any tyro could have decided these cases with the lantern.

The ophthalmic surgeon, although calling red and seeing it correctly generally, yet had but one name for the spring grass; that he was sure was red. His defect was first revealed by his insisting that a green ribbon on a lady's neck was red.

A similar case gave me much trouble and discussion on the P. R. R. where a signal-man, a member of a labor union, refused to acknowledge his color defect, detected by the stick by a lay-examiner, and spent much time and money in being coached with the color stick and wools by a local doctor, and by his wife with Holmgren's wools. My use of colored lights put his case beyond dispute, much to the credit of the lantern. He confused the green and red glasses from the test case when held one meter away. His selections of skeins from Holmgren are preserved on the card of bristol board.

He was reexamined several times, and had the sympathy of his Division Superintendent, who used the stick himself, and seemed unable to understand how a color-blind could pass the red and rose examination without a fault. The man seemed more anxious to overturn the wool tests of the road than to gain any advantage for himself. He finally, at the last interview, refused to submit to any test but the stick, and cut short his examination, refusing to look at any of my lights, where he knew he would be detected. He concluded by requesting me to sell him my sets of Oliver and Holmgren to continue his education. His card of wool selection indicates *green-red* defect.

May 31, 1901. Examination of applicant for Navy, U. S. C., act. 18, was found color-blind by wools and rejected.

R = 7/5.

V. L. = 7.5.

Never conscious of any defect. With the spectroscope he sees but two colors, yellow and blue, each fading to dark, with a gray band where they mingle. With Pole's pictures of spectra he says he sees some red in the normal one. Of his three squares of color, pink, green and gray, he says they are all in color, but the pink one is the most green. With my lantern he fails to call the red except in the 10 mm. size. He calls it green and red; and calls my three "confusion colors" viz.: pink, green and

gray, all a shade of white, or off white, without color. He calls the cobalt, blue; and the same when made pink by the blue of lower disc. He calls the blue light correctly and has a fine perception for this color. The greens he does not recognize. His feeble color sense.

With the color stick he selects seven greens and three browns with the green skein, and makes but one mistake with the red. He makes no mistakes with rose and is therefore not red-blind.

With Holmgren's wools he divides them into ten piles. The fact of mixing the pinks and greens indicates green-red blindness. The results are interesting. His grays are combined with light pink and light green. The lantern gave prompt and decided results and was superior to the wool tests. He is dichromic, seeing Nature with the red and blue sensations only. His selection of wools preserved on the card indicates green-red blindness.

These cases are rare and give rise to disputes when tested with wools alone. On the color-stick they pass the red and rose tests, since their red perception is enough to guide them, and fail only on perhaps five of the green, and confusion colors for green. An examiner without the clue to the green-red blindness hesitates and does not decide against a man who is so good on his reds. These cases form a sharp contrast with the usual ones of red-green blindness—with a shortened spectrum at the red end, where red perception is absent, and all the startling and fantastic phenomena of color blindness are found—viz., red matched with green in wools, rose with blue, inability to distinguish red fruits or flowers from their leaves, mistaking blood stains for ink, and speaking of the heavenly blue of the cheek of the best girl.

Mrs. S., the only color-blind woman of whom I have a record, I now mention to enable me to place before you her card as the best record of her defect in the wools selected and placed together from a Holmgren set. Her selection is a contrast with the others mentioned, and indicates the red-green blindness so commonly met with.

She was 50. Had been corrected for hypermetropia; full acuity of vision. From childhood color-blind. Two sisters were the same; her father and his brother, and her mother's brother were all color-blind. Of five sisters three are color-blind. Two sons are color-blind. One was tested by me with the spectroscope and had, like his mother, a spectrum of yellow and blue, both shortened at the red end, with a neutral band at the center. The mother tells me she had once bought a red dress for a black one, and could not distinguish one color from the other. Once her little daughter ran to her with blood on her white dress from a wound in the hand, and Mrs. S. exclaimed "Who has thrown that ink on your dress." Her card of preserved wools tells the story and indicates by its confusion colors with red and blue the red-green defect, which is her form of defect.

One more interesting record of a red-green railroad man remains. His selections are those usually met with in the use of the Holmgren and kindred wool tests. He was detected by the color stick, was one of the doubtful cases that demanded an expert examination, and furnished this valued record. His red indicates, as does his pink, an absence of red sensation.

Should color photography ever be perfected, such records as these, consisting of cuttings of wool selected by the five color blind described, could be not only preserved but presented for study to all interested in the subject as unique and faithful records of each case.

The use of the lantern here also disposes of all doubt of the presence of color-blindness with promptness and certainty and condemns the appli-

The long thread indicates the color to be matched, those below it those selected. The Figures I. Red; II. Yellow; III. Green; IV. Blue; V. Gray.

cant; but the diagnosis of green-red blindness requires the spectroscope, aided by a number of color screens or glasses to settle any controversies or doubts.

To conclude it appears that we may hope to render more clear the defects of the various wool tests. This seems desirable if we favor the use, where it seems proper, of non-professional examiners. My experience leads me to keep down the number of skeins in a set, and to insist on the use of tags with numbers that can be put on a written record, and submitted to the supervision of an expert on the subject. This has been done with the Color Stick and the New Wool Test, both simple forms of Holmgren's Test. Holmgren's test and instructions as usually employed presuppose that the examiner shall be able to furnish an infallible decision himself, which might be difficult for an expert of high training.

I am now of the opinion that the use of colored lights can be made by the layman to the saving of much time and needless discussion. My own conclusions have for years been formed from transmitted lights of various kinds, and I have offered a simple and effective form of a lantern for your consideration.

Queen and Co., supply the lantern accompanied by a certificate signed by Dr. Thomson of its accuracy.

A New Sign of Raynaud's Disease.—A. I. Pospeloff (*Medicinskoje Obosrenie*, June, 1901) observed a large number of cases in which Raynaud's disease was associated with biting at the nails, and he therefore concludes that a symptomatic relation exists between the two. He explains this "bad habit" by the fact that in Raynaud's disease the circulation of the matrix of the nails is disturbed, exerting pressure on the nerve terminals. This produces unbearable pain and a sensation of fullness in the nails, compelling the persons thus afflicted to bite at the latter. [A. R.]

LIGHT AND RADIANCE IN THE TREATMENT OF
DISEASE.By GEORGE G. HOPKINS, A. M., M. D.,
of Brooklyn, N. Y.

ARTICLE II.

PULMONARY TUBERCULOSIS.

Few of us realize the tremendous mortality that pulmonary tuberculosis produces in every civilized community year by year. The very best statistics taken the world over credit an average of one tenth of the entire deaths to phthisis pulmonalis.

This formidable record should awaken in every member of the medical profession a desire to investigate, and prove or disprove the efficacy of every remedy that has apparently cured some cases.

From time to time spasmodic efforts have been made to discover some specific for this disease but so far without success. Detweiler, in his strong advocacy of open air treatment with super-nourishment started the wave of medical opinion which has ever since been gaining strength, that this disease is susceptible of cure. But it remained for Professor Koch to arouse physicians from their lethargy in regard to this affection.

I, like many others, was carried away by his statements. It was my good fortune to be able to secure some of the first lymph brought to this country. I took under treatment a dozen patients, not in hospitals but in private practice. The patients were watched by trained nurses night and day. The temperature was taken every four hours. The sputum was examined daily. The tuberculin was administered in exact accordance with Dr. Koch's directions. The greatest care was taken to have everything aseptic.

In only one of these twelve cases was there any apparent improvement. The tuberculin appeared to have a germicidal effect on the bacilli; myriads of broken down germs were visible under the microscope. This was all very well, but the number of live bacilli thrown off far exceeded the number found previous to the administration of the tuberculin. Notwithstanding the extreme dilution of the lymph, and the process of heating to which it was subjected, it was surprising to see so prompt a reaction as was shown in every case.

Dr. Goetsch has been experimenting for ten years with tuberculin, in much higher dilution than that used under Koch's directions when he first gave his discovery publicity. Now Dr. Koch approves of this infinitesimal dilution of Dr. Goetsch.

But the weak point of all this is that Dr. Goetsch will only treat cases that have not shown any febrile reaction. That is he must secure them at a stage of the disease when patients have no suspicion of having the disease, and physicians seldom see them. Send such cases to Detweiler or Trudeau and they will cure them without tuberculin.

Be tuberculin valuable or not, the world owes to Prof. Koch a debt of gratitude that can never be paid, in that he has awakened the medical profession all over the world to an active search for some specific to cure this white plague and to the belief that there is a possibility of securing such a remedy.

The blue glass treatment was another step in the right direction and where sunlight can be had, I

should expect a cure in every case in the stage of the disease treated by Dr. Goetsch.

The injection of the cavity in a diseased lung with a mixture of carbolic acid and iodine, as so successfully practiced by Dr. J. Blake White, is a remedy of great power. I have used it myself with some degree of success and without the least danger to the patient. The catalytic effect of medicines has been tried; but with this I have had no experience nor does it appeal to my judgment.

The X-Ray has been and is being tried; but as it has so much boney substance to pass through before reaching the diseased structure within the chest, there is great danger of doing damage to the superimposed tissue of the chest, if sufficiently hard tubes are used to penetrate the diseased lung. So I have not thought it safe to use the radiance in this lung affection.

But light is a powerful germicide and the actinic rays will penetrate even the deep tissue. In order that the patient may be able to tolerate a sufficiently powerful light to destroy the germs of disease some method had to be devised to eliminate the heat rays. This is done in Finsen's apparatus by quartz crystal and in a less degree by blue glass or a watery solution of alum; so that the patient can be exposed to a powerful electric light for an hour at a time with comfort, and will even sleep during the treatment.

That I might test the light treatment, I purchased a 50 ampere electric lamp with a 20 inch condensing lens and had this arranged with an adjuster so that at a distance of 15 ft. the light could be concentrated on a surface an inch in diameter if it should be desired. With this concentration the heat is so great that it fractured a strip of $\frac{1}{4}$ inch plate glass two inches in width at two feet distance and a strip of $\frac{1}{8}$ inch blue glass of the same width at six feet distance.

In using this powerful lamp a screen made of strips of blue glass is interposed between the patient and the lamp to cut out some of the heat rays. The chest of the patient is bared and the light concentrated to a circle from fifteen to twenty inches in diameter according to the tolerance of the patient. The exposures vary from half an hour to an hour and are given daily.

The first effect of the light is a diminution of cough and temperature within forty-eight hours. In most cases the temperature is down nearly to normal within the first week of treatment. I am accustomed to judge somewhat of the improvement by the gain in weight; this is taken the day of the first exposure and subsequently every two weeks. In every case the amount of expectoration is perceptibly diminished and the number of bacteria to the field very much diminished within the first week of treatment. This indicates a reduced tax on the system, as the reduction of the number of bacilli to the field and the smaller quantity of expectoration makes a smaller army of microbes to be fed at the expense of the patients system.

Several patients who on beginning treatment walked a block with difficulty at the end of two weeks could walk a mile. The beneficial effect on

appetite was always marked from the very first treatment. The cessation of the cough necessarily permitted better rest at night. It is remarkable with what rapidity symptoms are ameliorated under the influence of the concentrated rays of light.

No. 1. H. B. H., aged 33 years, born in Connecticut. Trained Nurse. Came to me November 17, 1900. Menstruation regular, urine normal. In her mother's family, grandfather, two brothers and four sisters have died of pulmonary tuberculosis. Her mother is a picture of health and has always been well. No member of father's family has had any tubercular disease. In July, 1900, while on duty at the Seaside Home, she found herself growing weak, and her duties fatigued her greatly. She had noticed a morning cough for a year past, but it did not alarm her. By August the cough became annoying and there was increased expectoration. This alarmed her and she consulted a relative who is a physician and he diagnosed tubercular infection. Sputum was first examined October 5th, and found to contain bacilli in "considerable numbers." She was then taking creasote *m xxxx t. d.* in capsules. *Tr. Ferri Chloridi m x t. d. Liq. Potas. Arsen. m viii* every other day, and Russell's Emulsion 3 ii t. d.

November 20th, light treatment was instituted. Medication was continued with the exception of the iron and Russell's emulsion, Turk's emulsion of cod liver oil in half oz. doses was substituted at the suggestion of Dr. Reynolds.

She was examined by Dr. Reynolds and myself. A cavity was detected in the apex of the right lung, but very small in size. Her pulse was rapid and weak. Skin soft and flabby. Eyes dull and heavy. Whole bearing indicated debility and malaise.

November 21st sputum was examined by Dr. Craig and found to contain bacilli of tuberculosis. December 20th he found little if any change. January, February, March and April, 1901, found them in gradually decreasing numbers. His May examination showed a few bacilli. April 23d, May 1st, May 18th, June 9th and July 16th examined by Dr. Willis S. Cummings, my assistant, and "no bacilli" found. On June 12th and 19th Prof. Van Cott made careful examinations and could not find any tubercle bacilli and congratulated the patient on the result.

The patient's normal weight previous to August 1900 was 120 lbs. Then she found that she had lost 6 lbs. On November 20th she weighed 114 lbs. She continued to gain until February, 1901, when her weight was 119½ lbs., one-half pound less than normal. Her temperature had never gone above 100°, but after the institution of treatment it began to fall and by March 1, 1901, became normal. The cough was promptly mitigated, and expectoration decreased to such an extent that it was often difficult to get a specimen for examination.

Physical examination from time to time by Drs. Reynolds, Cummings and myself indicated a gradual but steady improvement in the condition of the lung. In April Dr. Reynolds after examining the lung, pronounced it practically healed. May 12th Prof. A. Jacobi, who was visiting me, kindly consented to examine Miss B. and stated that "while there was evidence of degeneration having taken place, the process had evidently stopped."

The light treatment began with half hour exposures daily (except Sunday) on November 20th, 1900, and continued until June 15, 1901. Light treatment and creosote were discontinued at that date. July 16th her weight was 119 lb., cough had ceased, no bacilli in sputum, cavity apparently healed. The affection in this case has been stamped out and the patient cured of the results of this invasion of microbes.

No. 3. G. G. C., aged 37 years. Express Clerk. Nativity, New York. Married. Contracted cold in December, 1899. Health continued to decline and tuberculosis was diagnosed. He had his sputum examined in May, 1900 but no bacilli were found. On June 1st he had another examination made and the bacilli were present.

In spite of treatment which seems to have been intelligent and skillful he continued to decline in health. A cavity developed first in one lung and then in the other. In the fall it was thought best for him to go South and he went to Texas. The climate did not benefit him. On

the contrary he lost ground steadily till the middle of December, 1900, when he came home to die. His physician, Dr. Barnett, referred him to me on his return home. It was with great effort apparently that he came to my office on January 1, 1901.

He was greatly emaciated; there were good sized cavities in both lungs. His pulse was feeble and rapid. Temperature running to 103½ every evening. Cough distressing, expectoration free. Sputum contained large quantities of bacilli. In fact his condition was such that I was not anxious to place him under treatment. But at the urgent solicitation of Dr. Barnett I took him under treatment.

His first visit to my laboratory was accomplished with difficulty, although he had only one block to walk from the cars, which passed within three or four doors of his house, and it was only a ride of twelve blocks.

His medication was Turk's emulsion of cod liver oil, liquid peptonoids with creosote and Fowler's solution. His light treatment was daily exposures of one hour each from January 2, 1901, to June 1st.

His improvement was rapid and remarkable. At the end of the first week he walked from his house to my office without fatigue, the cough was greatly mitigated; sputum decreased in quantity; temperature not above 101°; appetite greatly improved; night sweats decreasing.

January 1st his weight was 131 lbs.; January 14th his weight was 134½ lbs., showing a gain of three and one-half pounds in two weeks. 30th, his weight was 137 lbs., a gain of two and one-half pounds in the second two weeks, or six pounds in a month. April 3rd his weight was 133 pounds, and has remained about that figure. By June 1st he was walking 5 or 6 miles a day. The sputum showed no bacilli. His lungs were clearing, and he felt perfectly well. He procured an out door position about the race tracks, and treatment was suspended.

This case is remarkable for the great and rapid improvement from the very start.

I have treated ten cases in all. In every case cough, expectoration, temperature and sudorosis have been relieved within the first few days. The appetite also has rapidly improved.

While the period of experiment has been less than a year, the success has been sufficient to warrant a continuance of the treatment. It seems to me that we are pursuing a plan of treatment that promises much in the future.

I would add a word of caution. The patients should not be exposed to cold without very careful protection for some hours after taking treatments as the pores are open. The sudden cooling of the skin after prolonged exposure to heat will overtax the kidneys and possibly produce congestion in them.

I would advise careful examination of urine in every case where treatment is being given. The treatment could be better carried on in a sanatorium. It is hoped that this paper may induce a number of the profession to try this method that its place may be determined as a therapeutic measure.

On the Treatment of Women's Diseases by Electricity. — A. N. Alexandroff, in a paper read before the Society of Obstetricians and Gynecologists of St. Petersburg (*Bolnitchnaia Gazeta Bolkina*, Vol. XII, No. 16), described a special method employing electricity devised by him as early as 1886, independent of Apostoli. By this method he treated a large number of gynecological cases with gratifying results. In five cases of amenorrhea complete recovery took place in three, while the other two became pregnant. In 4 cases of fibromyoma the growth disappeared; in the others it diminished in size. Out of 34 cases of metritis 26 recovered; endometritis was cured in 33 out of 41 cases. Out of 14 cases of oophoritis 6 were cured; of 10 cases of salpingitis 3 were cured; in 1 case of hydro-salpinx recovery took place. Thirty-three cases of perimetritis were treated, 22 were cured; 12 cases of parametritis, cured 11; perioophoritis 18 cases, cured 13; perisalpingitis 5 cases, cured 4. [A. R.]

DISCUSSION ON THE THERAPEUTIC AND DIAGNOSTIC VALUE OF TUBERCULIN IN HUMAN TUBERCULOSIS.

By G. A. HERON, M. D.,

of London, England.

In the autumn of 1890—all but eleven years ago—there took place in Berlin one of the most remarkable events that mark epochs in the history of medical science. At that time, in the beautiful capital of the German Empire, there were gathered together some thousands of practitioners of medicine. Among them were many of the highest rank in their profession, men whose names and whose works were well known to all students of medical literature. Great centres of learning, famous scientific societies, medical schools and colleges, sent their representatives. Both hemispheres, all countries of importance, were represented at this memorable gathering. The reason why the medical profession then flocked to Berlin was, not because a new method of treating tuberculosis had been announced, but because a new method of treating that disease had been made known, as the work of his own hands, by the man who shared with Lister and Pasteur the honor of having done most for the advancement of scientific medicine, and the consequent lessening of human suffering. The great gathering in Berlin in 1890 was but an expression of the admiration and respect in which Robert Koch was held; for it is certain that had tuberculin been first brought to our knowledge by a man not in the first rank of our profession the remedy would have been left to find its own way slowly—perhaps very slowly indeed—into notice.

With much enthusiasm, and with high hopes of its future usefulness, tuberculin was received in the autumn of 1890. Before the end of the following spring the remedy had to a very great extent fallen into disuse, and was damned as loudly as it had ever been welcomed. The outcry against the use of tuberculin—for it was nothing less than this—had for its chief cause the condemnation of its use by another distinguished German, Virchow. The patriarch of present-day pathologists said that, in his opinion, the use of tuberculin was fraught with danger to the patient. His reason for making this statement was that he had seen in the bodies of consumptives, who in life had been treated with the old tuberculin, evidence which convinced him that the drug caused destruction of the tissues around tubercular centres, and so set free the bacillus to do its work upon healthy tissues. Virchow maintained that, had the remedy not been used, the bacillus might have rested, harmless, encapsuled, as we know it often is, by tissues that have undergone an indurative process, and become fibrous. Now this statement of his views by a man so justly famous as Virchow at once attracted attention. There is, I think, no doubt that this expression of opinion greatly tended to deter men from using tuberculin, and to prejudice the medical profession everywhere against its use. And so tuberculin was both made and unmade in Germany!

Of Virchow's objections to the employment of

tuberculin I can only say that, in my hospital experience of its action, there has been observed no evidence of resulting spread of disease to seemingly healthy organs, or to neighboring tissues. The average stay in hospital of the first thirty-five cases treated with the old tuberculin by me extended to sixty-one days. There was, therefore, sufficient time in which to observe whether or not, in these cases, there was to be obtained clinical evidence in support of Virchow's views. In no case was this evidence found, and it was often searched for by other physicians besides those officially present in the wards.

It may be worth while to refer, in this connection, to a case treated by me with the new tuberculin in hospital, and selected for that treatment because the patient was certainly slowly dying of extensive and advanced tuberculosis of both lungs. Dr. Perkins, who is one of the honorary secretaries of this section of the Congress, and was then pathologist to the City of London Hospital, performed the *post-mortem* examination. He made special search for the presence in the viscera of centres of probable fresh tubercular infection, but found none. This patient received twenty-six injections of new tuberculin in forty-two days, and the doses ran from 0.0025 mg. up to 2.5 mg.

Koch had, in the plainest words, and on several occasions, stated that cure of tuberculosis, when it affected the lungs, could be reasonably looked for, with the help of tuberculin, exclusively in those cases where only a small portion of one lung was infected to a slight extent, and where, of course, there was no evidence of excavation of lung tissue. He also said it would be reasonable to hope for a cure when only a small portion of each lung was diseased, there being no evidence of excavation. Any departure from these types of cases, in the direction of increase of the extent of the disease, lessened, by so much, in Koch's opinion, the chances of a cure; although even in more advanced cases amelioration of symptoms was he believed, likely to result from the use of the remedy. Now hospital experience taught me that it is seldom we have there an opportunity of treating these early cases. Therefore it is not common to find in hospitals the cases in which cure of the disease can be reasonably expected. So far as my experience of private practice goes, I must say the majority of cases in which I have been asked to advise as to the use of tuberculin have been too far advanced in tuberculosis to permit of high hopes for the best result of the treatment being obtainable. But when in unsuitable cases the use of tuberculin produces no good result, blame should not rest on the remedy. In my opinion, tuberculin has fallen into discredit:

1. By its frequent use in unsuitable cases.
2. By its administration in too large doses.
3. By neglect of the rule that a dose of it should never be given until the patient's temperature has been normal for the previous twenty-four hours at least.
4. By neglect of the rule, that the dose of tuberculin should never be increased, but, on the contrary, should be diminished, when its administration has been followed by a rise of temperature.

* From advance sheets furnished by our representative at the Congress on Tuberculosis, London.

5. By the prejudice raised against the remedy, among both doctors and patients, because of the severity of the symptoms, which not seldom follow upon its use.

Sir, I am obliged to crave indulgence of this meeting. It has been, if I may be allowed to say so, a very bitter disappointment to me, that in consequence of a long illness, which, until a fortnight ago, unfitted me for work, I was obliged to relinquish the treatment of the cases I had began to observe for the purposes of this discussion. Therefore, I am unable to present to you the new work which it was my earnest wish and intention to have submitted to you to-day, and I can deal only with work I have already published.

Since the end of 1890, fifty-seven cases have been treated with tuberculin by me at the City of London Hospital for Diseases of the Chest. Fifty-one of these were examples of tuberculosis of the lungs, and six of lupus vulgaris. Of these, five of the lupus cases and twenty-seven of the others were treated with old tuberculin.

One case of lupus, and twenty-four cases of tuberculosis of the lung, were treated with the new tuberculin.

At the end of the year 1900 seventeen of the fifty-one cases of lung-disease had been lost sight of, practically from the time they left hospital. Sixteen of the remaining thirty-four were then known to be well, and earning their living. I ask you to bear with me while I touch upon a few of the more important features—as I deem them—of these cases.

Whether consumptives leave a hospital well or ill is a very small matter compared with the answer to the really important question: How many of these people are able to work for their living, and for how long a time did they continue to gain their livelihood? I think the return to useful life of sixteen out of thirty-four cases of tuberculosis of the lungs, is not altogether an unsatisfactory result of treatment, and this result was obtained with the help of tuberculin. According to our information at the hospital, ten of these sixteen cases of recovery are known to have remained well and able to work for seven years, three for over three years, and three for nearly two years. Other patients remained able to work for periods varying from a few months to eighteen months; but as they are known to have broken down in health they are not included among these sixteen cases of apparent recovery.

Thirty-two of these fifty-one cases left hospital in 1891. Seven years afterwards—in June, 1898—the information concerning these cases, obtained, for the most part, by the assistant medical staff and nurses of the hospital, was as follows:

Eight of them were dead.

Ten were well.

One relapsed in 1897, having remained well until the autumn of that year.

Thirteen were lost sight of very soon after they left hospital.

These patients were all treated by the old tuberculin, and their cases are dealt with in some detail in a paper I contributed to Vol. XIV. of the *Transactions of the Medical Society of London*.

In addition to these thirty-two cases, five cases

of lupus vulgaris were then treated by the old tuberculin. These cases all did remarkably well up to a certain point, and then, at longer or at shorter intervals, suffered relapse. In one of the five a relapse did not set in until more than a year after she left hospital, and she would not return for treatment because she said she could not afford to give the time necessary for this purpose.

Some of these cases of lupus vulgaris relapsed while under the influence of tuberculin. It is certain that at this period of the history of tuberculin cases of lupus received unnecessarily high doses of the drug. When relapse took place in, for example, three of these cases, one of them had gained ten lbs. in weight, and was taking 400 mg. doses of tuberculin; the second was taking 1000 mg. doses, and had gained 10 lbs. in weight; the third had gained 18¼ lbs. in weight and was taking doses of 1000 mg. These large doses were given once in a week or a fortnight, and were in these cases not followed by high temperature, nor by other symptoms due to the action of the drug. The patients had been respectively 124, 128, and 135 days in hospital, and had received in that time the first-named 50, and the other two 59 hypodermic injections of old tuberculin. It seems to me difficult to believe, that these large doses could have exercised any material influence in the direction of favouring any tendency to relapse. The evils said to result from tuberculin are ascribed to its violent effects upon the tissues, by which, during severe reactions, infections of neighboring healthy tissue is, according to Virchow's observations, apt to happen. But in these cases there were certainly no reactions when large doses of tuberculin were given, beyond slight redness round the site of the lupoid patches. There were no headaches, no rigors, no high temperatures; and yet, in these circumstances, a relapse did take place, and while the drug was being administered. If the tubercle bacilli were let loose into the tissues, near the patches of lupus, as a result of severe reactions early in the treatment of these patients, then the drug should, one may reasonably urge, have had ample opportunity to exercise a beneficial influence, owing to the administration of the very large doses, which were not followed by reactions worth noticing. Certainly, in all but one of my lupus cases, tuberculin seemed, after a certain time, to lose its power for good. I confess I have never been able to understand why, in cases which had improved so much, certainly because of treatment by tuberculin, relapse should have occurred while the treatment was in full use.

Since March, 1897, I have used only the new tuberculin. During that year ten cases were so treated in hospital. Two of these cases died. One of them was the man whose case I have already spoken of as having been selected because he was certainly dying. The other eight cases of this year were made up of seven examples of tuberculosis of the lung, and one of lupus vulgaris. They all did very well, and, without exception, left hospital, urging as their sole reason for leaving their fitness for work and their wish to resume work. In December, 1900, three years after treatment, the following

was the result of the use of tuberculin in these ten cases:—

Two were dead; both of them recognized as being hopeless cases from the first;

Three were well and supporting themselves by their work;

Three were lost sight of;

One remained well until lately, and returned to hospital a few weeks because of a recurrence of disease.

No. 10 of the patients of the year 1897 is worthy of some notice. It is the only case of lupus I have treated with the new tuberculin, and it is the only case of that disease, which, in my hands, has not suffered relapse. He was a coachman, 27 years of age, admitted to hospital on April 17, 1897, with lupus vulgaris affecting the whole of his left nostril, both within and without; about one half of the anterior part of the right nostril, within and without; and the bridge of the nose between the alae nasi, excepting the tip of the nose. The left lip close to the middle line, at junction of lip and alae nasi, was also diseased. There was another infected spot of skin threequarters of an inch in front of the lobe of the right ear. This patch was about the size of a sixpence. Treatment with new tuberculin was commenced April 20, 1897, and completed August 4, 1897. Total quantity of tuberculin injected (hypodermically) 126.5 mg., given in sixty-three injections; the doses ranged from 1-300th part of a mg. to 4 mg. On July 2 scar tissue only was seen over sites of lupus patches, excepting the patch on the left lip; this had entirely healed sixteen days earlier. On February 25, 1898, I showed this patient to the Clinical Society of London. He was then free from recurrence of the disease. To complete this part of the case I may say he was quite well on June 9, 1898.

In the discussion which followed upon the exhibition of this case at the Clinical Society, it was asserted that the diseased condition I have described to you was due to syphilis, and not to lupus. In my notes laid with the case before the society, it was stated that the man had a history of gonorrhea followed by the sore throat. On his shins were two or three brownish stains, which, together with the history just mentioned, made it not improbable he had syphilis. He said he had never had skin disease until the appearance of the lupus patches on his nose. They began, he said, with a pimple. You will observe in this connection that it was stated in the hospital notes of the case, that there was on July 2, only scar tissue over the sites of the principal lupoid patches. On July 5 this patient, in going about the hospital, hit his shin sharply upon the angle of the chair. The skin was bruised and cut, and the patient suffered considerable pain in consequence. When, a day or two after the accident I saw the shin, it was very tender, and the man complained of pain. I ordered him to have gr. 5 doses of iodide of potassium, and this treatment was continued for a week. He was then free from all uneasiness, and the swelling was gone. The use of the iodide was then permanently discontinued.

It seems to me that it can hardly be fairly argued that this episode of the iodide had any effect upon

the skin disease that had affected the nostrils, but practically was cured before the iodide of potassium was first given. Another point about the case is, that the patient's temperature, taken for a week before the first dose of tuberculin was given, was normal. After a dose of 1-300th of a mg. of tuberculin, his temperature rose in twenty-four hours to 100.2°, and after a dose of 1-100th of a mg. to 100°. This patient's temperature charts show that he was peculiarly susceptible to the influence of tuberculin. Doses of 1 mg. caused temperature of over 102° on three different occasions, and $\frac{3}{4}$ ths of a mg. caused similar temperatures to be recorded. To my mind these facts are most important in helping us to a diagnosis of this case.

At this discussion of the Clinical Society of London, one dermatologist of note, and a well-known laryngologist were emphatic in their statements as to this case being one of syphilis. I hope I shall not be blamed because I attach more importance to the behaviour of this patient's temperature under the influence of tuberculin than to the expressions of opinion to which I have referred. The laryngologist was particularly convinced as to the accuracy of his observations, and that the case was one of syphilis, because, he said, he smelt dead bone in the patient's breath, and saw evidence of dead bone on inspecting the patient's nasal cavities with his laryngoscope. Four months after that expression of laryngological opinion, the patient was quite well, and had shown no evidence of the presence of dead bone in his nose or elsewhere; but whether or not his breath smelt of dead bone I cannot tell, because my nasal acumen in that direction is obviously untrustworthy, for I could not at any time detect the odor of dead bone which was so plainly revealed to the no doubt specially educated olfactory system of the laryngologist.

In 1899, ten patients, five men and five women, were treated in the wards with the new tuberculin. Of these five women two are known to be still in good health. One of the two is a domestic servant, the other is a shorthand writer and typist. Two other women are reported to have broken down in health. The fifth has not been heard of since she left the hospital.

Of the men, one continued well for more than a year after treatment, but appears to have recently had a relapse. He worked as a hawker, and so supported himself. Another seems now to be as well as he was when he left the hospital, and is said to be able to work. The third died November 16, 1900; the cause of death was not stated to us, but he was carried from his work, and two months afterwards died in his bed. Probably he died from a relapse. The fourth was reported to be very ill a year ago. The fifth is working as a photographer's assistant, but he says he had spitting of blood two months ago.

In Krause's record of his six years' experience of Koch's method of treatment of tuberculosis, he states that of twenty-seven of these cases, twelve are well, thirteen improved in health, one in *stat. quo*, one is worse. It is, of course, not possible on an occasion like this to go into details at any length; but some authors have more or less emphatically dissen-

ted from the outcry raised against the use of tuberculin, *e. g.*, Hansen, of Bergen, Osler, Gøtsch, McCall Anderson, Petruschky, Spengler, and others. Those of us who have dissociated ourselves from the outcry against tuberculin, have all expressed the view that in cases of tuberculosis, which fall within the limitation laid down in 1890 by Koch, great benefit to the patient is sure to follow upon a proper use of tuberculin, and very often there is complete disappearance of all symptoms of activity of the disease.

By far the most important communication, after Koch's own, that has yet been made to the literature that deals with tuberculin, was published by Dr. Gøtsch of Slawentzitz, on May 1, 1901. If the patient can well bear the old tuberculin, Dr. Gøtsch conducts the whole treatment of the case with it, beginning with so small a dose as .00001 gr. If this small dose should cause a rise of temperature, then Gøtsch goes back to the new tuberculin, giving it in doses of about .001 mg. Having felt his way by carefully avoiding the use of doses which would at all raise the temperature, or produce other symptoms of reaction, Gøtsch substitutes in the treatment the old for the new tuberculin. Since 1891 Gøtsch has treated 224 cases of tuberculosis, not of the lung only, but of all tissues. Of these he says he has cured 71%.

The record of these cases is most interesting, and the reading will, I think, carry, to any unprejudiced mind, the conviction that Gøtsch has given us a very important new departure in the use of tuberculin.

Responsible opinion is unanimous in its recognition of the worse than uselessness of any attempt to treat with tuberculin tuberculosis that is complicated with other inflammation. These mixed infections, as they are called, were not recognised in 1890, and it is only within the last few years that their great importance as complications of tuberculosis, whether of the lungs, of the skin, or of any other tissue, has been clearly apprehended.

Is there good ground for the belief that tuberculin, when properly used, is dangerous in any degree to the patient? From my own experience—and I am responsible for over 2000 injections of it—I am strongly of the opinion that it is, at least, as safe to the patient as is any other very potent drug.

Having said this, I will ask your attention to a statement of a case of great interest, which, in all its details, is well known to me.

A girl, seventeen years of age, was submitted to a test injection of tuberculin, because her physician had a doubt as to whether or not the girl had tuberculosis. She was thin and undersized. There was dull percussion over both lungs and abundant crepitant râles filled them both from apices to bases. Her liver and spleen were enlarged. No tubercle bacilli were found in the sputum. When the question of giving this girl a test dose was discussed, it was decided that, lest her symptoms should be due to tuberculosis, only a minute dose of old tuberculin should be given. Therefore, instead of the usual initial test dose of 1 mg., one-third part of a mg. was injected in the usual

way, and with, of course, strict attention to antiseptic precaution.

I show you an enlarged copy of this patient's temperature chart. The temperature was taken in the mouth, and the chart records in morning and evening for eleven days previous to the injection of the tuberculin. From the time of the injection onwards, the temperature was taken every four hours. Before the injection, the temperature, you will observe, ranged between two to four points below 98°; up to a point or two above 99°. After the injection the temperature never rose above 98°, and it fell on the last day to 96.4 and 97°. Respiration rose gradually from about twenty to double that rate. The heart's action became feebler and feebler, until she died twenty-seven hours after the giving of the injection. There was vomiting two hours, and again three hours after the injection. For the last twenty-four hours of life the patient had diarrhea, not bloody.

It happened that two other women, and two men each received the usual test dose of 1 mg., taken from the same bottle that had been used in this fatal case. Both of the women had moderate reactions, but one of them became jaundiced, and had a considerable amount of vomiting. The other woman had a rise of temperature of 102°, and no other symptoms, excepting only a slight sense of headache. Both the men had severe reaction with rigors, and a rise of temperature in one case of 104.4°, in the other to 102°. The man whose temperature reached 104.4 had vomiting, which, at intervals, continued for five days.

I need not say, a series of cases like this demanded a most rigid investigation as to the cause of these deplorable results, plainly associated, as they were, with the injection of these test doses.

As regards the case ending in the death of the patient: that the death was not due to tuberculin seems beyond doubt, for dangerous symptoms have, so far as I know or can ascertain, never been observed to follow a dose of less than 1 mg. The characteristic of the action of tuberculin is a rise of temperature. Here the temperature fell. Vomiting is a not infrequent symptom of a severe reaction, but here there was no evidence of reaction due to tuberculin. Excepting only this case, I have no knowledge of diarrhea having ever followed upon the use of tuberculin. But the symptoms of jaundice and vomiting in the other woman and the five days of occasional vomiting which occurred in the man, made it certain something was wrong with the tuberculin used in these cases. It was contained in one of several bottles, all filled with tuberculin of the same date of manufacture; the date being one month and eleven days previous to the giving of injections. All these bottles were sent to Dr. Macfadyean of the Jenner Institute. They were unopened, excepting, of course, that one which had already been in use. He examined their contents by every method known to bacteriologists. He says in his report: "The tuberculin was injected into guinea pigs, 1 cub. c.; 0.5 c.c., and 0.2 c.c. No toxic effects were produced, nor any noticeable symptoms." Dr. Macfadyean ends this report with these words: "I have not, therefore, been able to trace any abnormal or deleter-

ious property in connection with the samples of tuberculin. . . ."

The doses of the drug were made up by a most efficient druggist, who was well accustomed to the preparation of minute doses, dispensed with the use of the metric system of measurement. Careful enquiry made it certain there could have been no error in the dosage. Of course every effort was made to secure a post-mortem in this case, but the necessary permission could not be obtained.

One may speculate upon the cause of this death; and it may be suggested, with much force of reason, that it was due to widespread and advanced degeneration of the intestinal glands. But the absence of post-mortem evidence and the want of all help from the bacteriological examination, must, I fear, for the present, bring us face to face with a deadlock in seeking to explain this case.

The fact that this girl showed no reaction proves to the minds of, I think, all those who have much experience of the use of tuberculin as a test for the presence of tuberculosis in human and other animals that it is highly improbable she had tuberculosis. What, then, is the diagnostic value of tuberculin? That it produces its characteristic reaction wherever tuberculosis is present, there can be no doubt. That it rarely fails to react where there is tuberculosis is so true, that cases in which failure is recorded may safely be neglected. In my own experience of this use of it I have never seen any evil consequences follow its administration. It produces no evil effects in such cases as disease of the larynx, nor in kidney disease with albuminuria and granular tube-casts, nor in disease of the bladder, nor, so far as I know, in any condition of disease, whether tubercular or not. As an illustration of the practical usefulness of tuberculin as a test in cases always difficult and often impossible of diagnosis by ordinary methods, I would refer to the excellent work done in this direction by Dr. Eric France, of the London County Asylum, Claybury. His object was to ascertain, with certainty, who among the insane inmates of the asylum had tuberculosis. For this purpose he tested fifty-five of his patients with tuberculin. Characteristic reactions occurred in forty-five of these cases. Thirty-four of them eventually died, and twenty-nine of these thirty-four were submitted to *post-mortem* examination, with the result that, as Dr. France says, "Active tubercle was found in every case." Ten of the fifty-five patients did not react. Five of those died, and *post-mortem*, says Dr. France, "No trace of tubercle found in any; five still alive and healthy." Here is his expression of opinion on this matter in his own words: "I injected fifty-five cases with tuberculin, and personally I am satisfied, not only with the accuracy of its diagnostic power, but also with its entire harmlessness, both in the tubercular and in the non-tubercular."

We know, Sir, that the best, I had almost said the only, chance of cure of the consumptive is to treat him in the earliest days of his illness. It is a fact, that by no other means can we so early diagnose tuberculosis in men as we can by the help of tuberculin. It is also a fact, that we can do this with safety to the patient. Had tuberculin served no

other good purpose than this, it would have deserved our best attention, our high appreciation. I am sure the day is not distant when the discovery of tuberculin will be ranked among the most valued of the many gifts mankind already owes to Robert Koch.

PRESSE MEDICALE.

June 29, 1901. (No. 52).

1. Primary Cancer of the Bronchi. PIERRE MERKLEN and J. GIRARD.
2. The Symptoms and Diagnosis of Injuries of the Sinuses of the Dura. GEORGE LUYB.

1.—While cancer of the lung often starts in the bronchus, primary carcinoma of the larger bronchi has been observed during the past few years only. Such a case is reported, in a man of 45, whose mother died with cancer of the breast. Dyspnea was first noted about six months before death. This grew so severe that he could not swallow. His voice was inaudible, and his breathing became a roaring, interrupted by paroxysms of coughing, with bloody expectoration. The right lung showed absolute dullness upon percussion. Autopsy revealed cancer of the right bronchus almost at the bifurcation of the trachea. No air entered the right lung. Death generally follows from asphyxia. [M. O.]

2.—The main symptom attending injury of the sinuses of the dura mater is hemorrhage. Coma follows, with stertorous respiration, hemiplegia, subnormal temperature, vomiting, fecal and urinary incontinence, carpalgia, etc. The diagnosis is very difficult. Injury of the sinus must be distinguished from cerebral compression, due to the pressure of the bone upon the brain; cerebral apoplexy; concussion of the brain, and meningo-encephalitis. Even then, intracranial hemorrhage may not be caused by injury to the sinus, but by injuries to other blood vessels of the brain substance. [M. O.]

July 6, 1901. (No. 54).

1. Chronic Constipation. FROUSSARD.
2. Asepsis of the Hands in Surgery. L. LONGUET.

1.—Chronic constipation may be total, when the bowels move but once or twice a week, or dissociated, when the stools are few, small in amount, little in quantity, or very hard and dry. Associated with chronic constipation are noticed all the symptoms of dyspepsia; sometimes, too, of neurasthenia. The general health of the individual is affected and some emaciation occurs. Relaxation of the abdominal wall follows. As a rule, dissociated constipation, as in mucomembranous enterocolitis, is first noticed, and this becomes total in time. Among the cases of constipation are displacement or tumors of the abdominal organs; intestinal obstruction; changes in the intestinal contents; disease of the intestines; and atony, the most common of all causes of constipation. It is most frequent in adult or old age, in women, after pregnancy, with sedentary occupation, with lack of exercise, etc. The diagnosis is easy. For treatment these cases may be grouped into three classes:—those due to compression of the intestine; those due to intestinal atony; and those due to intestinal spasm. The first group will need operation to effect a cure. Patients with atonic constipation need strict diet; purgatives, whether mechanical, like castor oil; biliary, like calomel; intestinal, like manna or salts; muscular, like belladonna, nux vomica, etc.; or peristaltic, like rhubarb, senna, cascara, etc.; enterocolysis; massage; baths; electricity; and exercise. Patients with spasmodic constipation should have a full diet, castor oil, belladonna, enterocolysis, baths, and rarely massage. Gymnastics and electricity are contraindicated. A regular life, with well regulated mild exercise and no intellectual work, should be led. [M. O.]

2.—Asepsis has taken the place of antiseptics. All surfaces are now made sterile. Everything employed in an operation reaches this standard except the hands of the operator. It is only in the last ten years that the Germans have sought to obtain this end. England, America, and France have followed. Numerous experiments have been performed. After a detailed review of the subject, Langueit admits that as yet no good method of sterilizing the hands of the surgeon exists. [M. O.]

Criticism of the Medical Attendants of President McKinley.—As an aftermath to the lamented death of President McKinley, there have appeared, unfortunately but perhaps inevitably, in various journals and from various sources considerable criticism on the conduct of the case on the part of the attending physicians, which has not been confined to the lay press that is supposed to be more or less uninstructed and therefore not quite so capable of judiciously criticising, but also is apparent in some of the medical journals.

The chief features that have met with criticism are three; and only these three are really worthy of notice. These are, first, that a physician presumed more thoroughly familiar with the cardiac conditions than any attendant upon President McKinley should have been called in consultation from the beginning of the case. It seems to be forgotten by these critics that in addition to Drs. Mann, McBurney, Wasdin and others, Dr. Rixey, a man who has not devoted himself exclusively to surgery, and who was probably more familiar with the physical condition of the President than any other physician, was in attendance, and we believe he was not only thoroughly competent to manage the President's case, but that he did everything that possibly could have been done. Surely no treatment that is familiar to us could have altered the fatal result; and we are not aware of any medicine that could have been employed which was better than that given.

The second point is that food, and particularly solid food, should not have been administered by mouth as early as it was. Upon this point there is no doubt that a certain amount of discussion is justifiable. The medical profession has not reached any degree of unity regarding the proper time to begin feeding after operations upon the stomach. We can conceive that the feeding may have been injurious in two ways: either by hemorrhage from or by perforation through the stomach wall at the site of the injury. As a matter of fact neither of these occurred, and there is no reason to believe from the results of the autopsy that the feeding was harmful in any way. The physicians had the

choice of two risks, either of allowing the patient to become too weak from lack of nourishment or of injuring the wall of the stomach by the administration of food. They choose the latter, and who shall say unwisely?

Finally, there is much comment upon the very favorable character of the bulletins issued during the first days after the wounding. At that time the patient was doing well undoubtedly. There were no unfavorable symptoms, excepting, perhaps, the undue rapidity of the heart's action. The physicians believed that recovery was possible, and believing this, it was their duty to the public to state the case favorably. Perhaps our knowledge that gun shot wounds of the stomach are exceedingly fatal in elderly persons might have caused them to have been a little more cautious, but that is all.

It is not too much to say that adverse criticism is premature before the appearance of the final report, and such adverse criticism from a medical journal is especially indelicate and contrary to the best recognized standards. One of our contemporaries, in its haste to record its adverse judgment, has been guilty of a remarkable solecism. Thus, the *Medical Record*, in its criticism of the case, publishes two sentences, one immediately following the other, which we reproduce in parallel columns for the sake of a more graphic effect:

"Every one knows that such an injury as existed in the President's case is uniformly fatal."	"The most favorable result that could have been expected was the healing of the wound, and the possible establishment of a fistula."
--	--

It will puzzle the ignorant to understand how any favorable result whatever could be expected in the case of an injury which every one knows is uniformly fatal. The truth is that such cases are *not* uniformly fatal. Alexis St. Martin recovered from a severe gastric wound more than three quarters of a century ago, and Dr. William Beaumont made the case classical.

The Value of a Hopeful Prognosis.—Those who may feel inclined to criticise the surgical conduct of

President McKinley's case, should recall clearly the fact that if any error was made it was simply one of prognosis. Such an error is always on the right side of the balance, and is more to the credit than to the discredit of the human nature that is prone to show itself in a medical man when he is brought suddenly face to face with a great crisis. In the case of the President, the favorable prognosis did not and could not affect the result unfavorably. The work of the surgeons had already been done.

We take it as a well established fact in practice that a hopeful prognosis is better than despair in any case and under any circumstances whatever. There is a real and genuine asset to be derived from hope, and the individual who comes in for the biggest share of this asset is the patient. The tristful or lugubrious doctor who cannot see some silver lining to the cloud in an essentially doubtful case, should retire. He is not in the psychological mood to avail himself of all his opportunities. One of Philadelphia's ablest clinicians (now dead) once lectured on a case presenting doubtful symptoms of cancer of the stomach, and told his students that if he were the patient in such a case and his physician should make the positive diagnosis of gastric cancer, he would instantly discharge him. And this was said with reason; for of what use can a doctor be when he has abandoned hope?

In President McKinley's case the progress from the third to the fifth day fully justified a hopeful prognosis. Any other would have recklessly thrown the public into a panic, and this would have reacted disastrously upon the case itself. If these hopes were somewhat too buoyantly expressed, this was due to nothing more than the natural rebound from the frightful shock and anxiety of the first three days.

Harmony Among the President's Doctors.—The vicious extremes to which yellow journalism can go in this country were well shown last week in the attempt made by more than one New York newspaper of that stamp to stir up strife among the surgeons in President McKinley's case. It was currently reported in Buffalo a few days ago that a representative of one of these newspapers had openly declared that his paper was in possession of "interesting" facts relating to the subject, and that these facts would make splendid sensational matter now that the immediate excitement over the President's case had subsided. Anything more characteristic could not be conceived. It might be supposed that yellow journalism were sufficiently under a cloud already because of its ribaldry toward the late President, and that as a mere matter of self-preservation it would elect to lie low.

We are happy to be able to state on the direct

authority of Dr. Mann in a personal interview (supplementing what the whole staff had just said over their own signatures) that the most complete harmony prevailed all through the progress of the case. It is indeed a cause for congratulation that in a case so fraught with national sorrow, the bearing of all the physicians and surgeons has been a fine example of the force of professional esprit and tradition.

The Theory of the Poisoned Bullet.—In a case of such absorbing interest as that of our late President, it is but natural that theories and counter theories should have been advanced. The state of mind of the profession is reflected by those who have waited patiently for the result of bacteriological and chemical examinations, and the larger number who have let their imaginations take full rein and have speculated as to the various probabilities. This speculation is not without profit. Every carefully advanced theory has something to be said in its behalf. Among the many phases discussed is the theory of the poisoned bullet. Before the untoward symptoms had appeared, the question was asked, could the assassin have poisoned the bullets, and if so, what might he have used; and what would have been the effects induced? In connection with a theory of this sort, it is well to remember that the usual causes are first to be considered as by far the most probable, and the less frequent causes are only to be sought when the first are excluded. The statement is made that the most thorough bacteriological and chemical examinations have proved that the bullets were not poisoned, and thus this theory may be permanently set aside. Had this been the 15th instead of the 20th century, the conviction would have been widespread that the missile of death had been anointed with some mystic poison of wondrous strength to aid in the deadly work. We have the advantage of being able to test a hypothesis of this sort and our credulity cannot be imposed upon. Toxicologists were interested in the possible poison which might have been used by the assassin. Various pure cultures of deadly organisms were mentioned. Some thought the accidental verdigris which had collected about the bullet, might have been the cause of the gangrenous condition. Curare, another poison, was suggested, and also snake-venom, but the clinical picture which the President's case presented, lent no color to any of these theories, save that of the micro-organismal, and the chemical examination has caused this to be set aside.

The Condition of the President's Heart Once More.—Since the President's death we have had

a surfeit of theorizing regarding its cause. Now that the poisoned bullet has been eliminated we are presented with such fine-spun speculations as the possibility of injury to the solar plexus, a peculiar idiosyncrasy of the tissues preventing their healing, although their vitality was otherwise unimpaired; or the injury of the pancreas producing a general gangrene of the impaired tissues. It is hardly worth while to talk about the solar plexus as the cause of death. Deaths ascribed to injury of this structure follow immediately upon the wound and are not long drawn out, as in the President's case. It is useless to attempt to discuss an idiosyncrasy of the tissues, when we did not know certainly that it existed at all, and the assumption that it did in this particular case is purely gratuitous. As for the pancreas, as far as we can discover from personal communication from the attending physicians, glycosuria or other symptom of pancreatic disease was never present.

On May of last year a discussion was held before the College of Physicians of Philadelphia upon the effect of anesthesia in heart disease. It was shown then that in valvular disease of the heart without muscular degeneration an anesthetic has little or no injurious effect (Finney). On the other hand, there is reason to believe that in myocardial disease the anesthesia may cause a fatal termination either by producing sudden heart failure (Mayo) or by causing a sudden exacerbation of the morbid condition (Stengel), and attention was particularly called to the fact that in these cases the patient might continue in apparently good health for several days after the operation and then go into a state of sudden collapse exactly as in the case of the President.

We do not believe that enough attention has been paid clinically to myocardial disease. Whatever the actual cause of death there is no doubt, however, that the President's pulse was a just cause for anxiety from the very beginning of the case, and that the terminal manifestations of the case were collapse and heart failure. Whether these were produced by the anesthetic acting upon an already weakened heart or whether the condition of the myocardium was such that the shock of the injury was capable of causing it ultimately to become insufficient, we do not know, but at least we shall await with keen interest the histological report upon the condition of the heart muscle.

Medico-Legal Aspects of Penetrating Wounds of the Stomach.—In view of the case of our late lamented President, the subject of perforating wounds of the stomach is worthy of special consideration. The medico-legal aspect has been

considered in a communication by Dr. Glitsch, of Stuttgart (*Allg. Medic. Central Ztg.*, 1901, No. 30-37). He says: 1. If there be found in the topographical limits of the stomach a penetrating wound of the abdominal walls, we may be certain in a case of a gun-shot wound, that the stomach has been injured, and in the case of cut and stab wounds there is, as a rule, but one wound in the stomach, whereas, in the case of a bullet wound, there are in the greater majority of cases, two wounds.

2. As penetrating wounds are followed by immediate death in the rarest cases only, vital reactionary symptoms will almost always render feasible the differentiation between vital and post-mortem lesions.

3. Stomach wounds with suicidal intent are extremely rare; if they do occur, it is a question of a gunshot wound intended for the heart. In these cases the form and location of the wound, as well as the condition of the point of entrance will be helpful.

4. Hematemesis, collapse and shock are not necessarily sequelæ of a perforating wound of the stomach; on the contrary, the latter may at the beginning present no symptoms at all, but generally, in the further course alarming symptoms develop sooner or later. Of importance for the sequelæ of a wound of the stomach are the presence of food, a lesion of the larger blood-vessels and the affection of abdominal viscera.

5. The prognosis of stomach wounds is favorable only in cases of immediate surgical interference; the forensic physician is to designate these wounds as lethal, and cases of spontaneous recovery cannot alter this decision. They are to be considered the exception, the fatal termination the rule.

6. A successful therapy of a stomach perforation can consist only in laparotomy and stomach suture.

7. If a case of perforation of the stomach comes under proper care and treatment at once, complete "*restitutio ad integrum*" may be accomplished anatomically as well as in regard to the faculty of work.

8. Subcutaneous perforations of the stomach (ruptures) are generally immediately followed by the gravest symptoms. Their prognosis is much more unfavorable than that of penetrating wounds of the stomach; in all cases laparotomy offers the only prospect of recovery. From a medico-legal standpoint a subcutaneous laceration of the stomach is to be considered as simply fatal.

Herpes Zoster Ophthalmicus.—The failure opportunely to make a differential diagnosis between erysipelas and herpes zoster ophthalmicus frequently entails serious consequences. Out of five cases

reported by Bane, of Denver, at the recent meeting of the American Medical Association, three were originally diagnosed as erysipelas, and one of the cases was treated throughout its course for that disease. A recent contribution to this subject by Dr. Robert L. Randolph, of Baltimore, contains the report of a case of herpes zoster ophthalmicus resulting in the loss of the eye, and also occurring in a case which was at first thought to have been a facial erysipelas by the family physician. We should not venture to state that this case resulted disastrously in consequence of an original error in diagnosis, but quote it as illustrating the frequency with which the two affections are confounded until coming under expert observation. The usual monolateral seat of herpes zoster ophthalmicus and its location along the distribution of the nerves are valuable from the point of differential diagnosis. In Dr. Randolph's case reported in the *Archives of Ophthalmology*, Vol. XXX, No. 4, 1901, the eye was progressively destroyed until only light perception remained, and its enucleation was required on account of beginning sympathetic irritation; and all this in spite of expert treatment. The futility in this case of the most approved ocular therapeutics seems to point to the fact that the *locus morbi* must be deeper seated, it having been frequently contended that the affection is due to an irritation of the Gasserian ganglion, and especially by uric acid. In a discussion on this subject at the American Medical Association, Dr. Risley, of Philadelphia, stated that in his four cases there were rheumatic and gouty diatheses. Perhaps ophthalmic surgery will yet evolve some surgical procedure for this treacherous and often destructive lesion.

The Northern Branch of the Philadelphia County Medical Society.—We think a wise step, that promises to be fraught with much good, was taken the other evening in the organization of a Northern Branch of the Philadelphia County Medical Society. The necessity for organization in the medical profession, not alone for scientific, but also for social and legitimate political purposes, is too obvious to require discussion here, and in a city of such vast expanse as Philadelphia, it is impossible, from consideration of time, distance and occupation, for any large proportion of physicians to attend meetings at any one point, which must necessarily be at great distance from many other points. The formation of this branch should presage the organization of other branches in different and distant parts of the city, and these, it is hoped, will constitute centers of scientific activity, and good fellowship. The form of organization is a matter that will demand

most serious consideration. What is needed is a concentration rather than a diffusion of energy, so that it would seem desirable that, as is contemplated, membership in the parent society should be a prerequisite for membership in the branch organization.

Oöphorectomy for Cancer of the Breast.—The interesting paper by Abbe in a recent number of a contemporaneous journal calls anew the attention of the profession to one of the recent innovations in surgery. The honor of having first directed the attention of the medical world to the efficacy of oöphorectomy in inoperable carcinomata belongs to a Scotch physician, Dr. George Beatson, who, in an admirable paper, presented at a meeting of the Edinburgh Medico-Chirurgical Society in 1896, suggested that the exciting cause of carcinoma of the breast lay in some pathological condition of the ovaries. His suggestion was based, primarily, upon the undoubted, though occult relationship that exists between the genital organs and the breast; and secondarily, upon the fact that the breast is one of the most frequent seats of cancerous disease. It is well known that impregnation and gestation produce an influence upon the mammæ, resulting in a marked but normal evolution of those organs; and Beatson claimed that it was not unreasonable to assume that in like manner an abnormal stimulus originating in the ovaries might afford an explanation for the development of mammary carcinoma. Scouting the parasitic theory of carcinoma, as supported by Korotneff and others, Beatson held that the so-called cancer-cells would eventually be demonstrated to be in reality germinal epithelial cells.

Advancing one step further, he concluded that if it be true that epithelial cells in the ovary and testicle become germinal cells through some influence in these organs, then by natural inference extirpation of the ovaries or testicles would exert an inhibitory influence on the proliferation of epithelial cells. Instituting at once a series of investigations upon the human subject on the lines thus laid down he proved conclusively that removal of the ovaries does undoubtedly influence the growth of carcinoma, though whether only temporarily or not he could not state positively. Stanley Boyd in 1897 was the next to make a careful study of the new proposition.

He applied the treatment in five simple cases with most gratifying results. He thought that it was in the highest degree improbable that the relationship between the oöphorectomy and the atrophy of the cancer-masses was other than causal although he failed to offer an explanation as to the

modus operandi. His working hypothesis was that the internal secretion of the ovaries in some cases favored the growth of the cancer, acting either upon the epithelial cells or upon the surrounding tissues; consequently in such cases removal of the ovaries would leave the tissue better able to cope with the parasitic cell. It was but a step further to conclude that the operation of oöphorectomy might just as well similarly influence cancers elsewhere than in the breast, and at Boyd's suggestion the treatment was applied to a patient suffering from extensive cancer of the cervix and vagina. The same year Hobday, of the royal Veterinary College, obtained definite results in three cases in which the operation was performed upon bitches suffering from offensive papillomatous cancer of the vagina. Other operators, including Cheyne and Herman, adopted the method with gratifying results. It must be noted that Beatson's method includes the administration of the thyroid extract in full doses shortly after the removal of the ovaries. Investigators have found that the inhibitory action of oöphorectomy in inoperable carcinomata is more decided if at the same time as much of the cancerous growth be excised as possible.

Older women, in whom there has already occurred an atrophy of the ovarian stroma, do not respond so promptly or so favorably to the treatment as do women who are passing through the period of sexual activity. It is also noted that the relief afforded by the employment of Beatson's method appears in from twenty-four to forty-eight hours, and in favorable cases is rapidly progressive. The paper of Abbe should act as a renewed impetus to further study in this direction. Any measure that will afford additional chances of prolongation of life to these unfortunate sufferers should be given careful study in the hope that a solution of this interesting surgical problem may be reached. It is worth noting, however, that W. Roger Williams has recently expressed the belief that oöphorectomy has in reality the contrary effect to that claimed by Beatson, namely, that it predisposes to cancer in the mammary gland and elsewhere. This adds another interesting aspect to the subject and renders it all the more necessary that further careful observations be made before any dogmatic statement as to the value of this mode of treatment be advanced.

The Pain in Renal Lithiasis.—Constant describes the various localizations of the pain in renal lithiasis in the adult, in the *Bulletin Medicale*, (June 1, 1901, No. 43). He has reviewed 259 cases. With simple gravel, bilateral lumbar pain existed in 75 cases; unilateral lumbar pain in 15; and abdominal pain in 7. With gravel and nephritic colic, unilateral lumbo-abdominal pain was present in 17 cases, bilateral in 9; unilateral ureteral pain in 6, bilateral in 4; hepatic pain in 2; genito-urinary pain in 15; unilateral iliac pain in 1; crural pain in 8; urethral pain in 2; and disturbances of sensibility in 9 cases. The pain is in most cases due to the position of the calculus. [M. O.]

Reviews.

A Manual of Surgical Treatment, by W. Watson Cheyne, Professor of Surgery in King's College, London, and F. F. Burghard, Teacher of Practical Surgery in King's College, London. Volume V. Lea Brothers & Co. Philadelphia, 1901.

This volume, which will be followed by two others before the whole field of surgery is covered, discusses surgical affections of the head, face, jaws, lips, larynx and trachea. In order that the intrinsic diseases of the nose, ear and larynx should receive the requisite attention, the authors of the work obtained a specialist in rhinology, otology and laryngology to write the chapters relating to those topics. Dr. H. Lambert Luck, Surgeon to the Hospital for Diseases of the Throat, Golden Square, is accordingly the author of nearly half the book.

The method of the authors in this volume, as in the others, is to devote its pages to treatment, and to discuss pathology, symptoms and diagnosis to a very limited extent. The work is intended for the instruction of practitioners, who are supposed to know from other sources the fundamental points, and who therefore consult this book for suggestions as to the most practical and efficacious means of treatment.

The authors have done their work well. They seem to have an great love for good English as for good surgery, and to know how to write as well as teach. The text is succinct, yet clear; the construction is nearly always correct, and there is no silly attempt at ornamentation. The surgery is modern, scientific and progressive. In truth, the authors have fulfilled the promise of their preface, and given the profession a model book on surgical therapeutics—model in what it says and in the way it says it. The surgical precepts and admonitions may be followed by medical men with great advantage to their patients. The literary style will, if imitated by every prospective medical writer, work a needed improvement in current medical literature. [J. B. R.]

Manual of the Diseases of the Eye, for Students and General Practitioners. By Charles H. May, M. D., Chief of Clinic and Instructor in Ophthalmology, Eye Department, College of Physicians and Surgeons, Medical Department, Columbia University, New York. Second Edition, Revised, small 8 vo., pp. XIII, 408, William Wood and Company, New York, 1901.

It is most interesting, that this, the second edition of this well known and favorably received work should appear within eight months' time after the publication of the first. Careful comparison shows that not only have numerous useful alterations been made in the text, but that most valuable additions have been placed throughout the subject-matter. Quite a number of new illustrations, particularly colored ones, have been judiciously inserted wherever they might prove useful.

It is quite safe to say that the author has succeeded in producing one of the most comprehensive, concise, and practical manuals of diseases of the eye that we now possess; in fact, the only one that gives so many of the certainties of ophthalmology to the special student and uninform general practitioner. [C. A. O.]

Practical Dietetics. Food value of Meat, by W. R. Latson, M. D., Editor of *Health Culture*, The Health Culture Company, Publishers, New York.

It is the object of this author to decry the use of meat as a food. "Vegetarianism and vigor" go together according to his views. He does not believe that milk should be used as a food other than for sucklings. To this man we do not suppose that whatever may be said upon the other side will appeal in the search after health and longevity. It is well to remember that tuberculosis from which one out of every seven in the population is known to perish, is extremely rare among those who use meat largely as a food, and one of the later methods of treatment of this disease, zomotherapy, is based upon feeding with muscle juice in order to increase the resistance of the organism to the disease. The urea treatment has a similar object. To those of us who are inclined to believe that a mixed diet is of greatest value, this book will not appeal, and to vegetarians we would not suggest that the work be used as a tract, for the exposition of the subject is by no means convincing. [T. L. C.]

Die Serum-, Bakterientoxin- und Organ-Praeparate. Ihre Darstellung, Wirkungsweise und Anwendung. Für Chemiker, Apotheker, Aerzte, Bakteriologen, etc. Dargestellt von Dr. pharm. Max v. Waldheim. 800. p. viii. 401 Vienna, Pest, Lelpsic. A. Hartleben, 1901.

Although the employment of blood-serum from immune animals, of the products of bacterial activity and of preparations of various glandular structures dates back scarcely more than a decade, the field of investigation in this connection has been greatly enlarged and the practical results secured have been eminently satisfactory. Of the truth of this statement the brochure before us is ample evidence, for in it will be found discussed—in the first part—25 morbid conditions in which treatment with blood-serum from immune animals or with the products of bacterial activity has been employed—not always with the desired results it is true; and—in the second part—28 different organs or tissues, preparations of which have been employed in the treatment of various morbid conditions—likewise not always with the anticipated success. Although of the large number of disorders and of preparations considered favorable results can be recorded in only a minority of instances, the book is useful in showing the vast amount of work that has been done and it must prove serviceable to those interested in exhibiting wherein success and wherein failure has been obtained. [A. A. B.]

Medicinal Treatment of Diabetes Mellitus.—Dr. Archibald Dixon (*Medical News*, Sept. 14, 1901) reports a series of cases of this disease treated with satisfactory results. He says wisely that one or two successful cases are not enough to warrant judgment of the merits of any drug, but at the same time he claims that the combination of gold and arsenic known as arsenaurol has proved highly efficacious. He thinks the deductions made by Stucky are correct and that in the combination of gold and arsenic we have an agent which is the direct cerebro-spinal stimulant. In the combination there is developed an action entirely different from either gold or arsenic separately, which by its glandular stimulating properties aids elimination and feeds the nervous system, thereby checking waste, stimulating the cord, brain, glandular digestion, and by its reconstructive power lessens disturbances of metabolism. In a typical case the treatment was with bromide of gold and arsenic, in the combination known as arsenaurol, 5 drops after each meal, increased by 2 drops each day. The usual directions were followed as to diet. The improvement in the case was marked. The decrease in the quantity of urine passed and in the amount of sugar present was evident the first week. In three weeks there was barely a trace of sugar, and the urine was much reduced in quantity. Later the urine had become normal in quantity and the sugar had entirely disappeared. The eczema and pruritis caused by the diabetes had also disappeared. As Dixon says, the number of drugs which have been recommended for diabetes is legion, but in the one here alluded to he thinks we have found a reliable remedy. [M. R. D.]

Taylor, (*Annals of Gynecology and Pediatrics*, May, 1901), in speaking of the nausea and vomiting occurring during pregnancy, remarks that the chief causes of this complication are: (1) Deficient excretion due to carelessness in regard to personal habits; (2) Certain mechanical reasons, the pressure made upon the rectum, ureters and bladder by malpositions of the uterus, or by various tumors with or without adhesion due to previous pelvic diseases; (3) Nervous irritability. Under this heading he includes vomiting due to irritation of the vomiting-centre in the medulla oblongata, either by some lesion of the nervous system, a brain-tumor, cerebral abscess, the effects of toxins carried to the medulla by the blood as in malaria, or by reflex irritation from some portion of the body which is organically connected with the medulla and generally with some portion of the pneumogastric. The so-called pernicious form of vomiting he claims is simply an intensification of the conditions above described, due usually to prolonged neglect or ignorance. Unfortunately there are too many women anxious to avoid pregnancy who will try by every means at their command to induce some physician to resort to the operation of dilatation of the cervix or emptying of the uterus by exaggerating the amount of their nausea and vomiting. [W. A. N. D.]

Correspondence.

THE CAUSE OF THE MILDNESS OF OUR SMALLPOX EPIDEMICS.

By F. J. RUNYON, M. D., Clarksville, Tenn.

To the Editor of the Philadelphia Medical Journal:

I have seen a number of efforts intended to explain the mildness of smallpox so prevalent for the last two years. So far no satisfactory explanation has been given. I believe the type of the disease varies from unknown causes, just as does the type of measles, diphtheria, scarlet fever, typhoid fever and other infectious diseases. Furthermore, so far as known, these diseases affecting the parent confer no immunity upon the offspring. Reasoning from analogy, it would seem that smallpox (or vaccination) would prove no exception, though this theory is well presented in your issue of September 14th, by Dr. Horace S. Jones, of Kansas, Mo. To further disprove this theory I will call attention to the two epidemics of smallpox occurring in the same settlement near Guthrie, Ky. In the first epidemic (spring of 1900), several hundred had the disease, and there were no deaths. That this was genuine smallpox the marks that many will carry to their graves leave no doubt. The second epidemic, (spring of 1901), was attended by a mortality (according to Dr. LeRoy, *American Medicine*, September, 1901), of 60%. Now there is a community living under identical conditions that one year suffers the inconvenience of mild smallpox and the following year the ravages of the same disease but in a most frightful form.

AN APPARATUS FOR THE RELIEF OF BILIARY FISTULA.

By W. H. HAYNES, M. D., Brooklyn, N. Y.

Seeing quite a number of patients with the sequelae of gall stone operations, such as hernia, fistula, cholecystitis, recurring attacks of colic, and overlooked stones, my attention was particularly attracted to the pitiable condition of those with fistulae from which a pint or two of discharge drained away every day, saturating gauze, absorbent cotton and clothing, making their life so miserable that, as one patient lately discharged from St. Luke's Hospital, New York, said "He would rather be dead than to remain in such a condition." To obviate this difficulty a former patient of mine, the Rev. Dr. Wheeler, of Coatesville, Pa., before coming under my care for the treatment of his recurring attacks of colic and fistula, of which he was cured and has since remained so, had constructed the following described apparatus which not only kept him dry, but also acted as a support for the accompanying hernia, namely two saucer like disks of tin or nickel plated copper (one of which is perforated by a large hole in the center) and soldered together at their outer rim; a sponge is placed in the cavity and then applied directly over the fistula and retained by tapes, strap, or bandage. The sponge absorbs the discharge, the cavity retains it, and the whole may be emptied as often as necessary and convenient, beside acting as a truss to support any hernia present. That there is a general need for such an appliance the number of cases I see leaves no doubt.

On the Treatment of Inflammations of the Mucous Membranes by Means of Light.—E. A. Pletnikoff (*Russische Gaceta Bolikina*, Vol. XII, No. 19) employed blue light in the treatment of 5 cases of acute catarrhal inflammation of the throat with the following results: 1. The course of the disease was considerably shortened; 2. Already after the first sitting the act of deglutition became much less painful; 3. The exudate disappeared after the first, or at the utmost, the second sitting; 4. The diffuse redness of the mucous membrane disappeared speedily after the second treatment; 5. The swelling of the tonsils diminished markedly after the first sitting; the fever also subsided after the first treatment. In employing this method of treatment the author uses a blue electric lamp of 50 candle-power and 100 volts. This lamp is placed in the center of a reflector at such a distance from the patient that he experiences no sensation of heat. The rays of the light are directed perpendicularly towards the throat and the tonsils. Each sitting lasts 10-15 minutes, with slight interruptions. [A. R.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Smallpox in Philadelphia.—The epidemic of a mild form of smallpox which has existed for some weeks in the northwestern part of Philadelphia has continued to spread in spite of the rigid disinfection and quarantine maintained by the Board of Health. During the week ending September 21st thirty-eight new cases were reported. While the great majority of these were located in the 28th Ward, there were scattered cases throughout the city. An injunction has been granted which will prevent the erection of the emergency smallpox hospital near the Municipal Hospital, so that all cases will continue to be treated within the Municipal Hospital grounds. The Public Schools in that section of the city have not been closed, nor have the health authorities any doubt that the disease will not be stamped out in the next four weeks. Orders have been issued to have all city officials vaccinated. The district vaccine physicians have begun house visits throughout the twenty-eighth Ward, offering to vaccinate all who wish it, gratis.

The North Branch of the County Medical Society.—There was a large attendance of physicians at a meeting in Bank Hall, Broad street and Columbia avenue, for the purpose of organizing a branch of the County Medical Society. Dr. Albert M. Eaton presided and made an address. Other speakers were Dr. T. H. Fenton, Dr. E. S. Perkins, Dr. A. B. Hirsch. It was decided that the North Branch of the County Medical Society shall include the physicians residing between the Delaware and Schuylkill rivers north of Fairmount avenue to Wingohocking street. A permanent organization was effected by the election of Dr. Eaton as permanent chairman and Dr. R. L. Pittfield clerk. At the close of the meeting forty-seven physicians had placed their names upon the membership roll. Permanent quarters have been secured in Bank Hall, and meetings will be held there once a month. The idea in forming the branch of the County Medical Society, it was said, is to provide a convenient meeting place for physicians living in the upper part of the city, who often, through professional engagements, find themselves unable to get to the meetings at Thirteenth and Locust streets. It is understood that a like branch will shortly be formed in the southern section of the city.

State Medical Society of Pennsylvania.—The fifty-first annual convention of the State Medical Society of Pennsylvania was held at Horticultural Hall Tuesday, Wednesday and Thursday, September 24th, 25th and 26th. There were three sessions daily. Several social entertainments were tendered the delegates by the County Medical Society, by the trustees of the Medical Faculty of the University of Pennsylvania, by the trustees and Faculty of the Woman's Medical College, by the trustees and Faculty of Jefferson College, by the Medico-Chirurgical College and by the Medical Club of Philadelphia, also by Dr. John B. Shoemaker and Dr. James Tyson.

Western University of Pennsylvania.—The following appointments have been made in the faculty of the Medical Department of the Western University of Pennsylvania: W. H. Ingram, M. D., Professor Histology, Pathology and Bacteriology. M. R. Ward, M. D., Professor Diseases of Nose and Throat. R. W. Stewart, M. D., Professor of Principles of Surgery and Clinical Surgery. J. J. Buchanan, M. D., Professor of Principles of Surgery and Clinical Surgery. S. L. McCurdy, M. D., Professor of Orthopedic Surgery. Geo. N. Munro, Jr., M. D., Professor of Legal Medicine. E. B. Heckel, M. D., Associate Professor in Diseases of Eye and Ear. T. L. Disque, Associate Professor in Genito-Urinary Diseases. E. M. Hild, M. D., Associate Professor in Materia Medica and Therapeutics. J. A. Hawkins, M. D., Associate Professor in Rectal Diseases. I. J. Moyer, M. D., Associate Professor in Clinical Medicine. C. O. Goulding, M. D., Associate Professor in Clinical Medicine. J. I. Johnston, M. D., Associate Professor in Clinical Medicine. B. M. Dickinson, M. D., Associate Professor in Clinical Medicine.

Women's Medical College.—At the opening of the 52d session of the Women's Medical College of Pennsylvania, on Wednesday, September 25, 1901, the introductory lecture was delivered by Dr. Caroline M. Purnell, clinical professor of gynecology.

Temple College Medical School.—The new medical department of Temple College was opened Monday evening, September 23, 1901, Dr. H. F. Hawley, professor of theory and practice of medicine and clinical medicine, delivering the address. The course will extend over five years, as the work is altogether in the evening. Already 25 students have registered. The amphitheatre of the Samaritan Hospital and of the Philadelphia College of Dental Surgery are to be used for clinical teaching. The faculty of the institution includes Drs. W. W. Fritz, dean and professor of anatomy; B. F. Hawley, professor of theory and practice of medicine and clinical medicine; W. F. Haehlen, professor of obstetrics and gynecology; S. Wolfe, professor of physics and clinical neurology; G. B. M. Zerr, professor of chemistry and toxicology; I. N. Salvicy, professor of materia medica, pharmacology and therapeutics; J. W. Chroskey, professor of ophthalmology; B. Reed, adjunct professor of hygiene; E. B. Gleason, professor of laryngology and otology, and H. F. Shifer, adjunct professor of physiology.

Vital Statistics of Philadelphia for the week ending September 21, 1901:

Total Mortality	379	Cases.	Deaths.
Inflammation of the appendix 2,			
bladder 1, brain 15, bronchi 6,			
heart 1, kidneys 15, liver 2, lungs			
21, pericardium 1, peritoneum 5,			
pleura 1, stomach and bowels 38,			
spine 1			109
Marasmus 25, inanition 18, debility 2			45
Tuberculosis of the lungs			42
Apoplexy 14, paralysis 9			23
Heart-disease of 17, fatty degeneration of 3			20
Uremia 7, Bright's disease 9, diabetes 3			19
Carcinoma of the face 2, breast 1, stomach 3, uterus 3, liver 1, tongue 1			11
Convulsions			7
Diphtheria	56		6
Brain-disease of 3, softening of 2			5
Typhoid fever	87		11
Old age 9			9
Scarlet fever	34		1
Abscess, pelvic 1, atheroma 1, alcoholism 1, asthma 1, anemia 1, burns and scalds 1, casualties 4, cholera infantum 7, cholera morbus 2, cirrhosis of the liver 2, croup, membranous 2, cyanosis 3, diarrhea 2, drowned 2, dropsy 1, dysentery 4, epilepsy 1, erysipelas 1, gangrene, senile 2, hemorrhage from stomach 1, hernia 1, jaundice 1, obstruction of the bowels 3, edema of the lungs 1, rheumatism 1, sclerosis, spine 1, septicemia 1, smallpox 4, sore mouth 1, sarcoma, stomach 2, stricture of the esophagus 1, suffocation 1, suicide 1, syphilis 1, tabes mesenterica 1, tetanus, traumatic 1, tumor, abdominal 1, ulceration of the stomach 1, unknown coroner case 1, whooping cough 5, wounds, knife 1			71

NEW YORK.

A Surgeon as Adjutant-General.—Dr. Nelson Herrick Henry, of New York City, at present Republican Assemblyman for the Fifth District, will be the next Adjutant-General of the State National Guard. Since the death of Gen. Edward M. Hoffman, of Elmira, last spring, this office has been filled by Assistant Adjutant-General Frederick Phisterer, who will give way to the new appointee on January 1, when Dr. Henry's term as Assemblyman expires. Dr. Henry first entered the State service as an assistant surgeon of the grade of first lieutenant, Twelfth Regiment, March 16, 1883.

By June 23, 1888, he had been promoted up to surgeon and major. On June 23, 1893, he was made Assistant Surgeon-General, S. N. Y., with the rank of colonel, and was honorably discharged on April 25, 1895. At the outbreak of the Spanish-American war, Dr. Henry was made surgeon of the National Guard with the rank of colonel, and later major and chief surgeon of division, United States Volunteers. At the close of 1898 Dr. Henry went back again to the staff of Major-Gen. Roe. This is the first time in the history of the State that a surgeon has been made Adjutant-General to the Governor.

McKinley's Physicians Make a Statement.—The following bulletin was issued from Buffalo on September 18th: "The undersigned surgeons and physicians who were in attendance on the late President McKinley have had their attention called to certain sensational statements recently published indicating dissensions and mutual recrimination among them. We desire to say to the press and public, once for all, that every such publication and all alleged interviews with any of us containing criticisms of one another or of any of our associates are false.

"We say again that there was never a serious disagreement among the professional attendants as to any of the symptoms or as to the treatment of the case or as to the bulletins which were issued. A very unusual harmony of opinion and action prevailed all through the case. The unfortunate result could not have been foreseen before the unfavorable symptoms declared themselves late on the sixth day, and could not have been prevented by any human agency.

"Pending the completion and publication of the official reports of the post-mortem examiners and attending staff we shall refuse to make any further statements for publication, and alleged interviews with any of us may be known to be fictitious.

"MATTHEW D. MANN,
"ROSWELL PARK,
"HERMAN MYNTER,
"EUGENE WADDIN,
"CHARLES G. STOCKTON."

The Assassin of the President Insane.—Before the trial of Czolgosz which began September 23d at Buffalo, it was learned that five specialists had already pronounced the assassin insane. These men were Drs. Allen, McLane Hamilton, of New York, Carlos T. McDonald, Hurd, Joseph Fowler, James W. Putnam and Floyd S. Crego of Buffalo.

A New French Hospital in New York.—Plans have already been prepared for the erection of a new hospital in New York by the French Benevolent Society, to cost about half a million dollars. A building of seven stories with accommodations for over 150 patients will be built on West 34th Street. The top floor will be devoted exclusively to tuberculous patients. In appointment and general equipment this hospital will equal, if not surpass, any hospital already in New York. The institution, which receives no aid from the State, will be non-sectarian. The amount expended was donated by the French Government and many Frenchmen both abroad and in New York.

American Electro-Therapeutic Association.—The eleventh annual meeting of the American Electro-Therapeutic Association was held at Buffalo, September 24th, 25th and 26th, 1901, under the presidency of Dr. Ernest Wende.

Dr. Gustav G. Fischlowitz has been appointed assistant attending surgeon to the New York Maternity Hospital.

NEW ENGLAND

The Fiske Fund Prize Essay.—The subject of the Fiske Fund Prize Essay for the year 1902 was announced at the annual meeting of the Rhode Island State Medical Society to be "Serumtherapy in the Light of the Most Recent Investigations." A prize of two hundred dollars is offered for the best essay upon this subject. Essays should be sent to the secretary of the board of trustees of the Fiske Fund, Dr. Halsey DeWolf, 212 Benefit Street, Providence, R. I.

A Bequest to the Massachusetts General Hospital.—The late Mr. Charles H. Hayden, of Boston, left \$100,000 to the Massachusetts General Hospital, a part to establish a bed in his name, the rest to be used or invested according to the discretion of the trustees of the institution.

A Hospital for Crippled Children.—Mr. A. C. Burrage, of Boston, whose child of nine is a cripple, has leased Bunkins Island for a period of 399 years. He will erect a Hospital for Crippled Children, with large and beautiful grounds, upon it.

Bequests to Hospitals.—The late George L. Young, of Boston has bequeathed \$5,000 each to the Children's Hospital, the Massachusetts General Hospital, the Boston Lying-In Hospital, the Massachusetts School for the Blind, and the American Unitarian Association.

A Harvard Man Wanted by Germany.—The Prussian Government has offered a full professorship in inorganic chemistry at the University of Göttingen to Dr. Theodore William Richards, assistant professor of chemistry at Harvard, but the offer has been declined by Dr. Richards, who prefers to continue his work in the Harvard laboratories.

WESTERN STATES.

Death of Dr. Abram Litton.—Dr. Abram Litton, the eminent scientist and pioneer chemist in St. Louis, who for 50 years filled the chair of chemistry, both at Washington University and the St. Louis Medical College, died at his home in St. Louis, September 22nd, at the age of 87 years.

Dr. Thomas W. Huntington, associate professor of clinical surgery in the Medical Department of the University of California, has been recently appointed professor of clinical and operative surgery by the Regents of the University.

University Changes.—Dr. Bourland is to leave the University of Michigan to accept the position of professor of Romance languages in Western Reserve University, Cleveland, and Dr. Ladd, son of Professor Ladd, of New Haven, will become the first incumbent of the Dr. Leonard Hanna chair in the Medical School of the Cleveland University.

The License to Practise Medicine in California.—A large number of physicians registered in the State of California prior to August 1st, 1901, when the new law requiring all physicians to pass an examination before the California State Examining Board went into effect. There are now about 4000 practicing physicians in California.

The Berkeley Hospital.—A site has at last been chosen near the centre of the town of Berkeley, California, for the erection of the Berkeley Hospital. The plans have already been prepared, but the \$15,000 necessary for its construction have not all been pledged yet.

A New German Hospital in San Francisco.—A prize competition has been opened for architects' plans for the new German Hospital of San Francisco, which will cost \$200,000. It will have a separate building for tuberculosis patients.

Diet Experiments.—The professors of the Rush Medical College, Chicago, will soon begin a series of experiments upon the students of the Chicago Hospital School, to determine the effects of different foods upon the mental power of the individual. The pupils of the school are all backward children.

St. Luke's Hospital, Aberdeen, S. D.—The new building of St. Luke's Hospital, which has just been completed, is said to be the finest hospital in South Dakota.

The Methodist Hospital, Indianapolis.—Land for the new Methodist Hospital of Indianapolis has been secured on Illinois Street. The new hospital will cost about \$200,000.

Rules for Barbers.—The San Francisco Board of Health requires barbers to observe the following rules: 1. Mugs and shaving brushes will be sterilized by immersion in boiling water after every separate use thereof. 2. Razors shall be wiped with alcohol before and after being used. 3. Hair brushes known as "sanitary brushes" must be used after being sterilized. 4. Razor strops must be kept clean, and never wiped off with the hand or blown upon with the breath. 5. A separate clean towel shall be used for each person. 6. Barbers shall not blow away with breath any hairs after cutting, but use a towel or bulb or hair-brush. 7. Barbers shall keep their finger nails short cut and clean. 8. Alum and other material used to stop the flow of blood shall be so used only in powder form and applied on a towel. 9. The use of powder puff, finger bowls

and sponges is prohibited. 9. No person shall be allowed to use any barber shop as a dormitory. 10. All barbers' instruments must be disinfected after using. 11. These rules shall be placed in a conspicuous place in the shops.

A Kentucky Decision.—The Kentucky Court of Appeals has decided that the State Board of Health has not the right to revoke a license to practice medicine, once granted.

Election of Officers.—The annual convention of the American Society of Obstetricians and Gynecologists, which has just adjourned at Cleveland, Ohio, have elected the following officers: President, Dr. Edwin Ricketts, Cincinnati; vice-president, Dr. Cumston, Boston; secretary, Dr. W. W. Potter, Buffalo; treasurer, Dr. X. O. Werder, Pittsburgh; Washington was chosen for the next year's convention.

Nebraska State Insane Asylum Destroyed by Fire.—The Insane Asylum at Norfolk, Nebraska, and eight adjacent buildings were destroyed by fire on September 23. Six hundred patients were in the institution at the time, three of whom are missing and supposed to have been burned to death. The patients are now quartered in an open field, and are guarded by local authorities until they can be sent to the Lincoln and Hastings asylums. The loss will reach \$200,000.

SOUTHERN STATES.

Dr. Rixey to be Promoted.—President Roosevelt has informed Mrs. McKinley, through Secretary Cortelyou, that, in pursuance of the intention of the late President McKinley, and in recognition of devoted services, as well as because of eminent fitness, Medical Inspector P. M. Rixey will be appointed surgeon-general of the navy upon the expiration of the term of Surgeon-General Van Ryeppen. The Secretary of the Navy has been requested by the President to instruct Dr. Rixey to make such arrangements as will enable him to continue, if needed, his care of Mrs. McKinley between now and the time of his appointment to his new position. The naval list shows that Surgeon-General Van Ryeppen will not retire in the ordinary course until November 14, 1902. Dr. Rixey stands No. 28 on the list of naval surgeons. Though Surgeon-General Van Ryeppen's retirement from active service does not occur for more than a year, his commission as surgeon-general, which was for a period of four years, will expire December 18, and Dr. Rixey's appointment may be expected then. Dr. Rixey has been Mrs. McKinley's physician since the beginning of the Spanish war, when Dr. Leonard Wood, who up to that time was her medical attendant, went to the front as colonel of the Rough Riders. He is well known in Washington, having been born in Culpepper, Va., hardly fifty miles away. His brother, John F. Rixey, who lives at Culpepper, represents the Eighth Virginia District in the House of Representatives. The family is an old one. Dr. Rixey has been in the navy twenty-seven years, having graduated from the Medical Department of the University of Virginia in 1873 and the Medical Department of the University of Pennsylvania two years later. The following year he received a commission in the navy as assistant surgeon. He ranks high as a surgeon, and has endeared himself by his fidelity and trustworthiness to the President's family. He not only attended Mrs. McKinley, but the President, and carried him through his severe illness last winter. Dr. Rixey was with the President and Mrs. McKinley throughout the trip to California, and the President attributed to his skill and good judgment the remarkable recovery which Mrs. McKinley made.

Dr. George S. Dare, of Rising Sun, Md., has been reappointed State representative in the Philadelphia and Baltimore Central Railroad Company by the Board of Public Works.

Appointment.—Dr. Charles M. Hazen of the Medical College of Virginia has been appointed professor of biology in the Richmond (Va.) College, his alma mater.

MISCELLANY.

Dermatitis Produced by a Caterpillar.—Dr. James C. White, of Boston, in a recent communication states: Last summer I saw at the clinic for skin diseases at the Massachusetts General Hospital a considerable number of cases of inflammation of the skin, which were undoubtedly

caused by contact with some caterpillar. The dermatitis was of the same type in all cases, and there was also a uniform history of the removal of caterpillars from the affected parts just preceding the appearance of the eruption. As such cases had not previously occurred under my observation, I concluded that the larva must be some recently introduced species. The parts affected were generally the neck, sometimes the face and hands. The efflorescence was urticarial in character, but very persistent; that is, remaining unchanged for two or three days. The lesions in some cases were arranged in long, continuous tracts, as if following the course of the creature upon the skin. The statements generally given were that the patient had been walking, or had sat under a tree, and had found the caterpillar crawling over the parts which were affected a few hours later. This season several patients have already presented themselves with the same peculiar, persistent itching, more or less confluent, urticarial eruption, chiefly upon the neck, and tell the same story. They all give the same description of the caterpillar, which is probably the larva of the brown-tailed moth, *suproctis chrysorrhæa*. The patients come from towns in this vicinity. The affection yields quickly to soothing washes."

A Worthy Departure.—One of the Buenos Ayres newspapers has a consultation room, in which the poor can daily get medical or legal advice free.

Laboratories for the Philippine Islands.—It has been enacted by the United States Philippine Commission that a biological laboratory, a chemical laboratory and laboratories for the production of vaccine virus and of serums and prophylactics shall be established and maintained by the government of the Philippine Islands.

A Second Bequest by Mrs. Whitelaw Reid.—Mrs. Whitelaw Reid has made a second gift of \$5000 to the Woman's Hospital in Manila.

The Recognition of Good Yeast.—Now that brewers' yeast is so generally employed in medicine, for the treatment of furunculosis, typhoid, gastroenteritis, etc., Jouissee has described a test for the recognition of good yeast, in the *Revue des Sciences Physiques*. He takes 30 g. of a sugar solution (1 to 10), adds 10 g. of yeast, and places this at a temperature of 30° C. In from 12 to 15 minutes a good yeast has begun to ferment.

The Antiquity of the Speculum.—It is plain from the Babylonian Talmud (*Traite Nidda*, pages 17 b. and 66 a.) that the ancient Hebrews used the speculum to determine whether hemorrhage from the vulva came from the uterus. This is noted by Dr. Schapiro in *La Province Medicale*.

Obituary.—Dr. John M. Meyer, at Danville, Ky., September 5, aged 84 years—Dr. Philip Schaffner Baker, at Asheville, N. C., September 2, aged 50 years—Dr. Alonza D. McComb, at Hawthorne, Pa., September 5, aged 47 years—Dr. Charles F. Atwood, at Winterport, Me., September 6, aged 45 years—Dr. William Washington Rigby, at Spartansburg, S. C., September 4, aged 30 years—Dr. Charles W. Adkins, at Langston, Ala., September 4, aged 60 years—Dr. J. M. Winn, at Forest City, Ill., September 5, aged 71 years—Dr. Samuel C. Edmonds, at Linwood, N. J., September 17, aged 72 years—Dr. William Morris, at Baltimore, Md., September 18, aged 65 years—Dr. John C. McKownen, at Wilson, La., September 18.

Dr. Abram Litton, St. Louis, Mo., September 22, aged 87 years—Dr. Clarence T. Stubbs, Reading, Pa., September 22, aged 31 years.

The Cause of Hunger.—A German has lately advanced the theory that hunger is caused by the absence of the blood from the gastric blood-vessels. In anemia, even when the stomach is empty, the blood-vessels of the gastric walls are congested. In health, the absence of the blood from the gastric vessels acts upon a special nerve, branches of which supply the mouth and tongue. Thus it is that a stimulus applied to the tongue creates appetite. Thus, too, disease of the mouth causes a loss of appetite, though the stomach be empty and the patient actually in need of food.

The Medical Schools of the United States.—The last number of the *Journal of the American Medical Association* gives a brief description of the 155 medical schools of the United States. It is claimed by all but two of these that a four years' course is compulsory. 26,147 students and 5,958

teachers were registered in these colleges in July, 1901. 5,444 degrees of M. D. were conferred during the past year. Canada has but 12 medical schools.

Climate and Old Age.—The *Pacific Medical Journal* is authority for the statement that the oldest living human being, Bruno Cotrim, living in Rio de Janeiro, is 150 years old. Germany, with fifty-five millions of people has 78 centenarians; France, with 40 millions, has 213; England, 146; Scotland, 46; Norway, 23; Sweden, 10; Belgium, 5; Denmark, 2; and Switzerland, none at all. Spain has 401 centenarians, while Servia, with a population of 2,250,000, has 575 people over one hundred years old. The difference in the effects of a high altitude and a warm climate is, from these statistics, striking.

The Money Value of a Woman's Life.—Legal decisions tend to show that a woman's life is worth but half that of a man. \$5000 has often been decided upon as the value of a man's life, as many decisions of the courts show, while the judgments recently allowed in two separate States, for damages for the deaths of women, amounted to \$2500 each. The Supreme Court of Maine reduced a judgment for \$3500 to \$2500, claiming that the former sum was too large to pay for the death of a woman who had only supported her husband and five children. The Supreme Court of New Jersey also reduced a verdict for \$5000 for a woman's life lately to \$2500. It is truly an odd view of life that is gained from the court room.

Suicide in Childhood.—It is a fact that suicide is continually increasing among the children of civilized people. A hundred years ago it was an almost unheard-of occurrence for a child to kill himself. Now, while suicides are commonly reported among the children of France, England, Italy, Switzerland, and the United States, Germany heads the list in the number of juvenile suicides. In Prussia alone, from 1869 to 1898, 73 boys and 20 girls under the age of ten years, and 1173 boys and 342 girls between the ages of ten and fifteen years, committed suicide. The younger children, in many cases, were totally ignorant of what they were doing. Of the causes for the prevalence of suicide in childhood, Baer, in a most interesting book just published in Germany, states that the most important are mental disturbances, such as the insanities and the emotions, love, hatred, jealousy, etc. In some cases alcohol was a distinct predisposing factor; while the tendency to commit suicide may be inherited. Poverty, hunger, fear, the early development of puberty, lack of education, etc., all lead to suicide. Baer lays especial stress upon society, balls, theatres, etc., which early awaken the sexual passions of growing children, especially of those about the age of puberty. A direct appeal is made to parents and physicians to help in the prevention of this growing evil among children, by a more careful attention to their education.

Population Statistics.—The *Review of Reviews* states that the population of Canada is rapidly increasing, since, among the French-Canadians, families of fifteen to twenty children are not uncommon, the average being over ten. From the latest English data, the decline in the birth rate in England is greater even than that of France. The condition in the United States is disguised by the number of immigrants continually arriving. In Italy the population has grown so rapidly that the United States attracts thousands of Italians annually. This is due to the fact that agricultural conditions are so much more favorable here than in Italy. Belgium and Switzerland not only hold their own, but are gradually increasing in the number of their people. In these countries the emigration and immigration almost balance.

Longevity of the Various Races.—It has often been remarked that while nothing is so uncertain as the duration of any given human life, nothing is more certain than the aggregate of years which may be assigned to a group of one hundred persons or more at any particular age. The expectation of life at a given age, to use the actuarial phrase, differs considerably, as might be expected, in different countries, and Englishmen may be surprised to learn that they are not the longest living among the white races. At the age of 20 an Englishman in average health may expect to live forty-two years, and any life office will grant him a policy based on that prob-

ability. The American's expectation is for a slightly longer period. On the other hand, a German lad of 20 can count upon little more than thirty-nine years and a half. It would seem, therefore, that the restlessness attributed to the American temperament does not necessarily conduce to the shortening of life, nor the composure of the German to its prolongation. Possibly the better feeding and clothing of Americans in the lower classes of the population is the principal cause of their greater longevity. Their position is, at any rate, maintained in later as well as in earlier years. The American who has reached 60 may look to complete fourteen years more, while the Brit- isner's expectation is only about thirteen years and ten months, and the German's as nearly as possible twelve months less. Both at 20 and at 60 the Frenchman's prospect is a little better than the German's and a little worse than the Englishman's.—*London Globe*.

Health Reports: The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, U. S. Marine Hospital Service, during the week ended September 21, 1901.

SMALLPOX—United States.

		Cases.	Deaths.
ILLINOIS:	Freeport	Sept. 7-14	1

GREAT BRITAIN.

The English Medical Schools.—The *Medical Press* states that there are 11 medical schools in London and 9 in the provinces, none of which themselves confer degrees. Besides these colleges, there are six universities: Oxford, Cambridge, London, Durham, Victoria, and Birmingham, which confer two degrees in medicine, M.B. and M.D., and two degrees in surgery, B.Ch. and M.Ch. The medical students who have been matriculated in London or the provinces come before the Conjoint Board for examination. This Board confers the degrees of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries also confers the complete diploma in medicine, surgery, and midwifery.

Typhoid Fever in Belfast.—The epidemic of typhoid fever in Belfast in June is at last beginning to abate. 217 cases were reported in June, 505 in July, and only 345 in August. At a meeting of the City Corporation held

upon September 1st, no single cause for the epidemic could be found.

Middlesex Hospital Chapel.—After ten years of work, the interior decoration of the chapel of the Middlesex Hospital has been finished. Those who have been privileged to see it state that it has a most beautiful example of marble and mosaic work.

CONTINENTAL EUROPE.

A Nursery for the Children of Lyons.—The late M. A. M. Rémond left his entire estate, valued at \$200,000, for the erection of a nursery for the use of the children born in the Maternity Hospitals of the city of Lyons.

Dr. Leopold Javal, the eminent ophthalmologist and member of the Paris Academy of Medicine, has been appointed an officer of the Legion of Honor.

A Centenarian.—In Nertschinsk, Russia, died a certain Mendel Berkovitch at the age of 110, leaving 119 grandchildren. The deceased has never been sick and died without any preceding illness.

The New Moon as a Hair Tonic.—In accordance with a superstition prevalent in certain parts of Russia and Germany girls cut their hair as soon as the new moon makes its appearance. The hair removed is rolled into a ball and thrown on the roof of the house. This, they believe, makes the hair grow to an unusual length. This superstition, surprisingly is shared by educated (?) women.

A Victim of Kneipp's Method of Treatment.—A woman who is a blind follower of Kneipp subjected one of her daughters, who fell ill with fever, to the following treatment. The girl was given a cold bath, enveloped in a cold wet sheet, and placed in a cold barn. The poor girl died on the following day. It is a wonder that such crazy fanatics are not taken care of by the law.

A Specimen of French Criticism.—The *Echo de Paris* publishes a medical expert's opinion on President McKinley's case. He declares that the operation was not properly carried out, because it was incomplete. It would have been better, he says, not to operate at all. Mr. McKinley, the expert states, had a chance of life before the incomplete operation, but none afterward. The expert concludes that the cause of death was peritonitis.

Busts of Chassaignac and Maisonneuve.—On September 26, 1901, busts of Chassaignac and Maisonneuve were unveiled in the court of the Hôtel-Dieu Hospital in Nantes, Professor Guyon presiding.

Dr. Korteweg, Professor of Surgery at Amsterdam, has been appointed Professor of Clinical Surgery at the University of Leyden, replacing the late Dr. J. E. van Iterson.

Dr. I. Novi, extraordinary Professor of Materia Medica, has been made ordinary Professor of Materia Medica and Experimental Pharmacology at the University of Bologna.

Dr. Heinrich Kionka has been appointed Professor of Pharmacology at the University of Breslau. **Dr. H. Sachs** Professor of Neurology at the University of Breslau.

Dr. G. Corrado, extraordinary Professor, has been made ordinary Professor of Medical Jurisprudence at the University of Naples.

The Incineration of Cadavers in Paris.—It is only recently that the Faculty of Medicine in Paris has begun the erection of a crematory for the incineration of the cadavers which have left the dissecting-room.

A French Commission for the Study of Yellow Fever.—The French Chamber of Deputies and Senate have unanimously voted the sum of \$20,000 to pay the expenses of a commission, consisting of three or four physicians, for the study of yellow fever. This commission, under the direction of the Pasteur Institute, will probably leave for Brazil in October next.

An Accident to Dr. Calmette.—Dr. Calmette, Director of the Pasteur Institute in Lille, was bitten by a snake recently, while collecting venom. A large amount of antivenomous serum was immediately injected. Though his hand and wrist were greatly swollen and he had high fever, he recovered rapidly.

The New Autopsy Amphitheatre in the St. Antoine Hospital, Paris.—In the St. Antoine Hospital in Paris, a new autopsy room has just been inaugurated. The walls are of white tiles, while the floor is in mosaic. The bodies lie in the cellar below, and are brought up upon an elevator in the vestibule, closing with a trap-door. Everything is scrupulously clean.

Swiss Mountain Climate.—Seven professors, some from Berlin and some from Vienna, supplied with a large scien-

tific outfit, have spent the last summer in the mountains of Switzerland experimenting upon the effects of the climate upon their circulation, assimilation and other physiological processes. Detailed reports will be published later.

THE JOURNAL OF NERVOUS AND MENTAL DISEASES. August, 1901. (Vol. 28. No. 5.)

3. A Large Subcortical Tumor of the Oculipital Lobe, Producing Right-Sided Hemiparesis and Right Homonymous Hemianopsia, together with Wernicke's Pupillary Inaction Sign as A Distance Symptom.

F. X. DERCUM.

4. A Case of Asternognosis Resulting from Injury of the Brain in the Superior Parietal Region.

WILLIAM H. TELLER and F. X. DERCUM.

1.—C. K. Mills says that the term **pseudo-tabes** has been applied to a variety of spinal and neural affections with symptoms closely simulating those of true tabes spinalis. The symptoms in pseudo-tabes are neuralgic or lightning pain, anesthetics, incoordination, bladder disturbances and lost knee-jerks, and if the sciatic distribution is affected, lost Achilles jerk. More or less marked atrophy may be present. In many cases the disease may be traced to some toxemia or infection, such as alcohol, arsenic, lead, dlatetes or syphills. The clinical diagnosis between these different affections and true tabes is made by a close study of etiology, of previous history and of the progress of the case, and is much helped by attention to a few symptoms which are usually present in the one case and absent in the other. [T. M. T.]

3.—F. X. Dercum reports a case of the above condition in which, at autopsy, the following was found: As soon as the calvarium was removed, it was noticed that the brain bulged considerably in the left occipital region, as though it had been under pressure. When the brain was removed a large hard mass could be distinctly felt lying deeply within the occipital lobe. It could be easily made out there through the lateral and mesial surfaces. The brain was subsequently hardened in formation and the exact situation of the tumor ascertained by horizontal section through the left hemisphere. There was found a hard yellowish white tumor, oblong and irregular in outline, 1.2 cm. below the lateral surface, 3 cm. from the apex of the occipital lobe, from 1.4 to 3.5 cm. below the mesial surface and 3.5 cm. from the basal surface. It was 7.4 cm. in its greatest width. From its situation it had evidently destroyed the fibres of the optic radiation. It did not, however, involve the optic thalamus or the quadrigeminal bodies. Its proximity, however, to these structures was such that they were probably influenced by pressure and it is extremely probable that the Wernicke's symptom observed upon one occasion in this case was a pressure symptom. The hemihyperesthesia and hemiparesis which were also present on the right side were evidently due to slight involvement and pressure upon the posterior limb of the internal capsule. [T. M. T.]

Investigations of the Plague.—D. Zabolotny (*Archiv Biologicheskikh Nauk*, Vol. VIII, No. 4) performed a series of experiments on a large number of monkeys, reaching the following conclusions: (1) In apes the principal clinical forms of the plague, the bubonic and pulmonary, can be easily reproduced. (2) A well marked infection can be cured by antiplague serum. (3) Injections of small doses early in the disease are preferable to large doses late in the disease. (4) Recovery from the plague is accompanied by phagocytosis in the bubos. (5) To establish a fixed active immunity repeated injections of the serum are necessary. (6) Injection of toxins or dead cultures is always accompanied by a marked leukocytosis. [A. R.]

1.—Intussusception means the catching up of one piece of bowel within another piece. The intussusception always occurs from above downward because the peristaltic action of the circular fibres of the bowel is from above downward, and it is by the energetic contraction of these circular fibres that the intussusception is produced. Anything that will excite vigorous peristaltic action is apt to produce intussusception. The symptoms of the condition are: (1) sudden abdominal pain, (2) vomiting, (3) the passage, with much straining, of a stool containing mucus, blood and scanty liquid feces, and (4) the presence of a tumor in the region of the ascending colon. Owen believes that medical treatment can afford no trustworthy means of curing this condition, and that prompt abdominal section is the only practical and scientific way of affording relief. [J. M. S.]

3.—Pitts opened the discussion on the treatment of intussusception in the Section of the Diseases of Children of the British Medical Association. After a study of 115 cases of intussusception, the author concludes that the following rules may be considered as covering the best method of treating the disease: (1) Try inflation only when the case is seen within a few hours of the onset and is not of a very acute character. In the great majority of hospital cases it is better to open the abdomen at once. (2) Inflation may be tried in certain other cases for the purpose of reducing the main portion of the intussusception, so that the incision may be made directly over the cecum. (3) When reduction is found impossible in chronic cases a resection may be generally done through an incision in the ensheathing bowel. (4) In acute cases, if gangrene is present or the condition of the bowel requires

its removal, a wide resection should be undertaken as rapidly as possible, and the ends brought outside the abdomen; continuity should be restored at a subsequent operation. (5) In exceptional cases of enteric intussusception resection and immediate restoration of continuity gives the only chance. Between 1860 and 1890 D'Arcy Power has seen 113 cases of intussusception. His experience with these cases has convinced him that the best method of treatment is to perform an abdominal section at the earliest possible opportunity, and to reduce the intussusception, if possible, without bringing the tumor into the wound. If, however, there is the least difficulty in reduction, it is necessary to make a very large incision, and to bring the intussusception outside the abdominal cavity. Eccles believes that immediate celiotomy is indicated for the relief of the condition. He believes that it is unwise to put a nursing child to its mother's breast within a short time after such an operation, because the act of sucking tends to stimulate the peristaltic movements, thus, it would seem, rendering recurrence liable. For the same reason he is an advocate of the use of small doses of tincture of opium after the operation. Tubby believes that the frequent recurrence of intussusception after irrigation or inflation is due to the fact that the condition was not entirely relieved by the process, although the palpating hand could detect no further tumor. He also believes that the patient stands a better chance if abdominal section is performed at once. In fatal cases, there is often a rapid rise of temperature just before death; this, he believes, is due to septic thrombosis in the tributaries of the mesenteric veins, due to some septic infection originating in the damaged condition of the bowel. Abbott believes that in hospitals, where the conditions are always favorable, operation is indicated in intussusception; but, in private practice, it is permissible to try to relieve the symptoms by inflation and injection first, and later to send the patient to a hospital. He explains the rise of temperature after the operation by the passage of fecal matter over the damaged mucous membrane. The symptoms often resemble those of tuberculous peritonitis. Bush believes in the importance of early operation in cases of intussusception. He is not in favor of irrigating an infected peritoneal cavity. White believes that the hyperpyrexia following operation is due to some trophic disturbance of the thermogenic centres. He believes that if the country practitioners gave morphine to arrest peristalsis after reducing the tumor that lesion would not be so likely to recur. The president, Eve, said that the unanimous opinion of the speakers was against the employment of inflation or injection, with the exception of Pitt, who would allow those measures in cases seen within a few hours of the onset. The arguments advanced against inflation and injection are: (1) They are very rarely efficacious; (2) they are not infrequently followed by partial reduction; (3) they are unscientific. [J. M. S.]

4.—Cases of general anasarca are occasionally met with, chiefly in children, but sometimes also in adults, which exactly resemble cases of Bright's disease; but in which there is no albumin discovered in the urine, and no abnormal condition of the heart to account for the dropsy. These have been called cases of essential or idiopathic dropsy. Herringham believes that it is not the loss of blood cells in anemia nor the failure of excretion in nephritis that produces this toxic condition, but that there is some original toxic poison, such as that of scarlet fever, which produces not only the nephritis or the anemia, but also the edema, the latter being coincident with, but not consequent upon, the inflammation of the kidneys, or the loss of blood cells. Scarlet fever is certainly a toxic disease, and it is possible that a chill is also due to micro-organismal invasion. It is then reasonable to suppose that in certain cases the toxic condition may produce dropsy without inflaming the kidney. [J. M. S.]

5.—Tubby says in selecting a muscle for grafting, one whose action is most nearly allied to that of the paralysed muscle should be chosen. Any faulty position of the foot should be corrected before operation. He has noticed that the circulation improves and the warmth of the foot increases after these operations and in winter chilblains do not occur. He has operated upon 11 cases. Four were for calcaneo-valgus; two for talpes-calcaneus; one for equino-valgus; three for equino-varus; and one for calcaneo-varus; and also on four cases of spastic paralysis of

the forearm and hand, by transplanting the tendon of the pronator radialis teres, with sections of the flexor tendons of the wrist. Of these 11 cases six have shown good and five fair results; in no case has failure resulted. The results of the four operations in the forearm have been good in three and partial in one. Tendon grafting is useless in ball-like joints where all the muscles are badly affected, and it should not be employed in slight cases of paralytic valgus or varus or in slight equinus. [F. T. S.]

6.—White has operated upon 11 cases, one of which concerned the extensor muscle of the thumb, while the rest were examples of foot palsy. Lengthening the tendo-Achilles with the transference of a slip from its outer side to the tendons in front of the ankle formed an essential part of each operation. The next most frequent procedure was to detach the tibialis posticus and to bring it in front of the internal malleolus where it was attached to the tendon of the extensor proprius pollicis or to the long extensor of the toes. The case of thumb palsy was treated by attaching the tendon of the flexor carpi radialis to the paralysed extensor tendons. But slight improvement followed. Of the ten foot cases one has been lost sight of; two have been operated on recently; and of the remaining seven six are greatly benefited. One case should be considered a failure. The following operation illustrates the method most frequently practiced. The tendo-Achilles was exposed and divided longitudinally into three equal parts; the two inner parts were used for lengthening the tendon by dividing them at opposite ends and allowing them to slide on one another until the requisite length was obtained, when they were sutured together. The outer third was severed as the os calcis, and sutured to the tendon of the extensor longus digitorum. The tendon of the tibialis posticus was united to the tendon of the extensor proprius pollicis. A tunnelling under the skin is made by a fine pair of Kocher's artery forceps to convey the active tendon to its place of surgical insertion. [F. T. S.]

7.—Caiger opened a discussion on the early diagnosis of the acute specific fevers in the Section of Diseases of Children of the British Medical Association. He thinks that there is no question as to the paramount value of Koplik's spots as a factor in the diagnosis, not only in respect to the early recognition of measles, but also in its differentiation from other affections that are liable to be mistaken for it at an early period of illness. These diseases are German measles, laryngeal diphtheria, catarrhal laryngitis and the morbilliform erythema following the injection of antitoxin. On the strength of these spots alone, the author has on several occasions been able to successfully isolate a patient in whom neither pyrexia nor the slightest indication of catarrh in the mouth or elsewhere could be detected until twenty-four hours had passed, and, in case of the rash, until the lapse of four days after the spots were first seen. In the early diagnosis of whooping cough from an ordinary bronchial cold, several authorities have claimed value for a minute bacillus that can be isolated from the grayish mucous pellets that are separable from the sputum after standing. The organism stains in a granular fashion, and can be grown on coagulated hydrocele fluid. In the bacteriological diagnosis of diphtheria there are, as is well known, several factors that lessen the value of the results. The author holds that when bacilli apparently conforming to the Klebs-Löffler bacillus both morphologically and in culture are found in a case in which the clinical aspect is negative, the bacteriological examination cannot be regarded as conclusive unless it includes the result of animal inoculation. When bacilli are found that conform to the Klebs-Löffler bacillus in their microscopical, cultural and staining characters, and the clinical appearances of the case are consistent with diphtheria, the bacteriological evidence may be held sufficient to establish the diagnosis. Failure to detect the Klebs-Löffler bacillus in a case which, from the clinical standpoint, is negative, is sufficient to exclude the diagnosis of diphtheria, provided the negative result has been confirmed by at least one subsequent examination. On the other hand, failure to detect the Klebs-Löffler bacillus, even though subsequent examination should also prove negative, cannot be held to exclude diph-

theria, should the clinical appearances be distinctly suggestive of that disease. The author wishes to attest the value of Nelisser's double stain in differentiating the Klebs-Löffler bacillus in ordinary cover-glass preparations. In the differential diagnosis between scarlet fever, tonsillitis and diphtheria, the condition of the throat is helpful. In scarlet fever the throat presents a tumid, velvety appearance, and the association of a raw, clean tongue is a combination not seen except in scarlet fever. In tonsillitis the exudation is usually limited to the tonsils, while in diphtheria it spreads to the surrounding parts. The differentiation between the rash of scarlet fever, measles and German measles is made from the period of incubation, the occurrence of vomiting, suffusion of the eyes and the condition of the glands. Ashby believes, with Dukes, that there are two diseases often included under the term rubella; the usual one with the long period of incubation, German measles, and a rare one, only diagnosable when it occurs in epidemics, which resembles scarlet fever. Poynton referred to an experience of an epidemic of an eruptive disease that broke out in a large boys' school which was diagnosed "fourth disease," but he was not prepared to say that the cases were not mild cases of scarlet fever. He referred to the resemblance between the rash produced by iodoform poisoning and the rash of scarlet fever. Williams is of the opinion that there are two types of German measles, the morbilliform and the scarlatiniform, and that the latter is distinct from "fourth disease." Sympton said that the circumoral pallor, mentioned by Calger, was an early symptom of great value in the diagnosis of scarlet fever. He is of the opinion that acute pneumonia should be put in the list of acute specific diseases. [J. M. S.]

8.—Thursfield studied the serum reaction in 100 children in the Hospital for Sick Children, Great Ormond Street. Of these 42 gave positive reactions. Of the 42 cases of typhoid fever that gave the reaction 40 gave it on admission; one case alone had the reaction delayed later than the first week of the illness, the other presenting it within the first week. Of the cases that failed to give the reaction not one had typhoid fever. Although the number of cases is small, the author believes that in children a positive serum reaction is trustworthy evidence of the presence of typhoid fever; that a negative reaction later than the tenth day of an illness is strong, but not absolutely convincing evidence of the absence of typhoid fever, and that repeated negative reactions are trustworthy evidence that the case is not typhoid at all. He believes that the test is of greater value in children than in adults. It is possible that the reaction occurs earlier in children than it does in adults. He believes that simple continued fever is a distinct disease in children. [J. M. S.]

9.—Abbott reports the case of a female child, aged 14 months, who presented an enormous cranium, prominent eyes, toothless jaws and deformed limbs. The chest showed a deep, longitudinal groove on either side at the outer part of the line of the costal cartilages, with prominence of the sternum and inner part of the costal cartilages and rachitic rosary. The spine showed one large posterior curve. The child was pot-bellied. The alae of the iliac bones were flattened and thickened, the clavicle, the humerus, the radius, the ulna, the femur, the tibia and the fibula were curved as in rachitis on both sides. Both feet were in the position of extreme varus and calcaneus. The child, which was one of twins, died. It was born of healthy parents, the mother having given birth to seven living children and having had eight miscarriages. The other twin lived, but presented to a less degree the deformities of the one that died. The author believes the case to be one of intrauterine rachitis, and, since the curves of the bones are the natural curves assumed in the intrauterine position, thinks the changes due to intra-uterine pressure. The curves presented by this baby are the usual curves of rachitis that are usually supposed to be due to muscular traction or to methods of progression and support of the body weight. This raises the question whether these curves have not more often really commenced at this early period and merely become more marked after birth. The question of congenital syphilis must be considered as possibly responsible for the bony changes *in utero*, and as a predisposing cause of the subsequent rachitis, especially in the light of the history of miscarriage. However, the absence of teeth, the large cranium, the pot-belly and the general kyphosis point to rachitis, and the author considers the case as the most conclusive yet published, from the

point of view of the curves being due to intra-uterine pressure. The post-mortem specimens presented the characteristic changes of rachitis. Sklagraphs were shown.

[J. M. S.]

10.—Stillés has operated upon more than 100 *herniae in children*. He says that in a large proportion of hospital cases the truss is unsatisfactory because of the ignorance of the parents, its inconvenience, the long duration of treatment and its uncertainty in bringing about obliteration of the funicular process. If there be any difficulty in keeping up a hernia he proceeds to operation even though the child be but a few months old. He says the operation is not only simpler but also less likely to be followed by recurrence than in adults. Out of 78 cases in which it was reported in 72 the sac did not communicate with the tunica vaginalis. The operation he performs is as follows:—Exposure of the cord, its coverings, and the pillars of the ring. Isolation, ligation and excision of the funicular process, closure of the ring by passing the sutures of cat gut through the inner pillar and conjoined tendon on the inner side, and through Poupart's ligament on the outer side, care being taken to leave room for the cord; and suture of the wound. Seven of the 100 cases were strangulated, the youngest two weeks old. There were seven cases of cecal hernia, and in three cases the sac was found to be tuberculous. Two cases have thus far recurred. [F. T. S.]

11.—Ewart and Dicklson report two cases of *chronic hydrocephalus in infants* which were treated by tapping and by the introduction of aseptic air in the place of the fluid. The authors draw the following provisional conclusions: (1) With due precautions the fluid of chronic hydrocephalus may be completely evacuated from the yet unclosed skull of infants, and aseptic air may be allowed to take its place. This operation may be repeated without detriment, and with scarcely more risk than belongs to the usual method of paracentesis. (2) In favorable cases of moderate effusion, such as case 2, a single operation may suffice. Continued oozing from the puncture for a few days after the removal of the tube is not unfavorable. (3) In case of considerable effusion an obvious indication is to relieve the brain from weight and from the pressure of the fluid. The evacuation is facilitated by the introduction of aseptic air. In the first case reported this method of treatment has proved to be of decided advantage. By a timely repetition of the operation a hydrocephalic infant may be enabled to carry the weight of the head, and, if the treatment is begun sufficiently early, permanent damage to the brain tissue may be averted and a normal development may, perhaps, ensue. (4) In large heads, whilst hydropneumencephalus persists, a considerable splashing sound is readily obtained. There is obvious risk in eliciting this sound by forcible succussion, and, for the same reason, any abrupt movement of the head should be avoided. [J. M. S.]

12.—Hatten finds that *suppurative pericarditis* is present in nearly 3% of the deaths in the records of the Children's Hospital. The paper in hand is based on six cases. The cause of the disease was fixed in all cases. In two it followed measles, while in the remaining cases it had followed pneumonia or bronchitis. There is no particular temperature curve that can be considered characteristic, although sudden falls, attended with collapse, are common. The pulse is almost uniformly rapid and out of proportion to any distress or discomfort that the child may exhibit. The respiration is usually increased, but maintains about its normal ratio to the pulse. Severe attacks of syncope are frequent; there is not necessarily any increase in the area of cardiac dulness; the apex beat may be in its normal situation, and no adventitious sounds may be heard. The subjects of the disease resemble those who suffer from empyema. [J. M. S.]

13.—Out of 769 necropsies on children under 12 years of age there were 65 which showed non-rheumatic lesions of the pericardium. In 57 of these there was tuberculosis of the membrane and in 28 there was pericarditis, apparently due to pyogenic infection. Out of the latter 28 cases, 11 presented actual pus or seropus in the pericardial cavity, and in 17 the pericardial fluid was only slightly turbid. In some of the cases in each group bacteriological examination showed the presence of pyogenic organisms, and in others the presence of associated lesions made the exist-

ence of those organisms almost certain. The organisms found by bacteriological examination were the pneumococcus and staphylococcus pyogenes albus. The pneumococcus predominated, and it seems to be the organism most frequently concerned in the production of purulent pericarditis in children. Pleuritis is a very common associated lesion, and probably antedates the beginning of the pericarditis in the majority of the cases. It, in turn, is usually dependent upon a pre-existing pneumonia. The presence of lymph or of turbid serum in the pleura involves the risk of *suppurative pericarditis* no less than it does an actual empyema. Furthermore, the infection of the pericardium may occur within a few days after the onset of the pneumonia or not until several weeks have elapsed, and only the empyema or pleurisy remains. In any case, therefore, in which exploration of the chest shows turbid serum or pus, especially if on bacteriological examination the fluid is found to contain the pneumococcus, free drainage by resection of a rib should be performed with as little delay as possible in the majority of cases.

[J. M. S.]

15.—Maxwell refers to the case of a Chinaman, whose scrotum was little more than a bag of pus. Fifteen days before he was seen he had been seized with a violent chill, which passed into fever, which persisted, in about ten minutes. A part of the scrotum sloughed, but the patient eventually recovered. In studying the cause of these cases the author was able to exclude gonorrhea, injury and the bites of insects. After examining the blood of the patients affected it was found that each patient was suffering from filariasis. Abscess formation may occur as an incident in the course of filarial disease, or as the first symptom of that disease. It may occur in any situation in which there is loose connective tissue, rich in lymphatics, and it is not always necessary for the abscess to form in the situation of the primary inflammation. The author does not believe that every case of abscess of this character is caused by the death of the parent worm, and is inclined to attribute the formation of the abscess to the blocking of lymphatic vessels. Filarial abscesses may affect the scrotum, where they may be found as suppurating hydroceles, as abscesses of the cord or as abscesses below the testicle. They may also attack the limbs or they may be intra-abdominal or intrathoracic. The temperature in this condition rises rapidly, following the chill; it remains high for from one to three days, and then falls by lysis, provided an unopened abscess is not left. [J. M. S.]

18.—Gimlette reports an epidemic of zinc poisoning among the soldiers stationed at Pahang, which was caused by drinking water collected from roofs covered with galvanized iron. The water had become contaminated with zinc in such proportion as to cause disease. The diseases were characterized by the fact that the gastric symptoms predominated over the nervous symptoms. [J. M. S.]

MEDICAL RECORD.

1. Pathological Physiology of the Animal Heat Economy and Its Relation to the Modern Theories of Fever. ISAAC LEVIN.
2. Foreign Bodies of the Nose and Ear. PERCY FRIDENBERG.
3. Some Ultimate Results of Gunshot Wounds caused by Mauser Bullets During the Late Spanish-American War. MEDWIN LEALE.
4. A New Operative Procedure for Treating Inflammation of the Posterior Part of the Eye. S. BUSHY ALLEN.
5. The Disadvantages of Copper Sulphate in Diseases of the Conjunctiva and Cornea. CORNELIUS WILLIAMS.

1.—Isaac Levin discusses the pathological physiology of the animal heat economy and its relation to the modern theories of fever. Pathological physiology of animal heat is closely allied with the normal physiology of the same subject. Food, or rather the process of its metabolism, is practically the only source of animal heat in the normal state of the organism. A number of physiologists have shown that a lesion of the corpus striatum near the nodus cursorius raises the temperature of the body three or four

degrees. This increase of the temperature may last for three or four days, and does not depend upon the temperature of the medium surrounding the animal. He has studied the pathological increase of animal temperature, fever. Under the influence of some pyrogenic cause, the small arteries of the skin contract, thereby lessening the amount of heat coming to the surface from the internal organs, as well as the amount of heat dissipated. This is in the first stage of fever. At the height of the fever the loss of heat is even increased sometimes, but the production is so much increased that it covers the increased loss, while in *stadio decrementi* the loss of heat is higher than the production, and as a consequence the temperature falls. Heat economy pathologically seems to resemble general metabolism inasmuch as it is the result of the joint work of many organs of the body; and fever, the most pathological state of heat, is in most instances a special kind of intoxication due to some substances not as yet well defined. Further work will have to show us the precise nature of these substances, and also to decide the question whether there is some central apparatus conducting all the complicated works of the heat economy, and what the nature and office of such an apparatus, if it does exist. [T. L. C.]

2.—Percy Fridenberg presents a paper on the recognition of foreign bodies of the nose and ear. The symptoms of nasal and aural obstruction are familiar, but it is surprising how patiently they are often borne. The method of diagnosing foreign bodies of the nose and ear are given at length and the treatment detailed, and the importance of the subject to the general practitioner is emphasized. [T. L. C.]

3.—Medwin Leale furnishes some ultimate results of gunshot wounds caused by Mauser bullets during the late Spanish-American war. The notes of 15 cases are furnished. In these cases with the exception of two, it is to be observed that, owing to the great velocity and rapid rotary action, the hardness of the outer shells, the shape and width of the bullets from modern small-bore rifles, and the long ranges generally maintained in warfare, most of the wounds on account of their trivial nature (the wounds of ingress and egress being usually small), heal rapidly, in the majority of cases, without suppuration. Tearing and laceration of the soft parts are usually slight and when bones are struck they are more often punctured than broken or splintered, which was the cause of the old leaden bullets with their great explosive effect and slight penetrating power. Primary and secondary hemorrhages are correspondingly reduced. [T. L. C.]

4.—S. B. Allen presents a new operative procedure for treating inflammation of the posterior part of the eye. He proposes to use Tenon's capsule for reaching the nerve and its head, for hot water injection. In this operative procedure, there are two sources of danger. First, the technique, opening the capsule, passing the catheter back to the nerve and maintaining it there with pressure of the water. Second, the temperature of the water. The method has been successfully tried on the rabbit's eyes with no appreciable disadvantages. [T. L. C.]

5.—Cornelius Williams discusses the disadvantages of copper sulphate in disease of the conjunctiva and cornea. He says that the objections to copper sulphate are so great and its advantages so much less than those of other and safer remedies, that it should be banished from our list absolutely. He believes that bichloride of mercury is far superior to copper sulphate in all conditions in which the latter drug is indicated. His conclusions are as follows: 1. Copper sulphate in ocular affections is maleficent in its effects. 2. Any good effect following the application of the solid copper sulphate in any disease of the eye may be obtained with the use of safer and practically painless means. 3. Trachoma is most successfully treated with weak solutions of silver nitrate, together with frequent

irrigation with weak bichloride solution in normal salt. 4. No application to an inflamed conjunctiva which produces a lasting pain should be countenanced. 5. Expression is not absolutely essential, yet much hastens the cure of trachoma. 6. A mydriatic should be used in every disease of the eye involving corneal lesions. 7. Copper has ruined more eyes than it has ever benefited. [T. L. C.]

MEDICAL NEWS.

September 21, 1901. (Vol. LXXIX, No. 12.)

1. The Case of the President.
2. Disappearing Tumors. A. S. WARTHIN and W. A. SPITZLEY.
3. The Dilatation of the Cervix Uteri in Obstetric Practice. HENRY J. GARRIGUES.
4. The Pantherapist and Neotherapeutics. C. H. KERNOTT.
5. A Case of Double Penis, Combined with Exstrophy of the Bladder and Showing Four Urethral Orifices. CARL BECK.
6. A Case of Congenital Absence of Internal Genitals; Fusion of Kidneys; Single Ureter. ALLEN J. SMITH and WILLIAM GAMMON.
7. A Few Remarks on a Generally Unrecognized Ear Disease (Otitis Media Mucosa). HENRY A. ALDERTON.
8. The Local Treatment of Gonorrhea. E. O. BARDWELL.

2.—A. S. Warthin and W. A. Spitzley conclude in the article on disappearing tumors as follows: (1) That in spite of skillful clinical observation, the ultimate behavior of a tumor is seldom to be determined except by microscopical examination, and that many seeming malignant neoplasms are taken to be such when really they are but the outcome of an inflammatory condition; (2) That probably no true neoplasm, malignant in nature, ever disappeared except through retrograde changes induced into itself through infection of the tumor tissue, or through affections or infections of other parts of the body having, by reason of toxins, practically the same effect. To this there are extremely rare affections in which the disappearance of the growth takes place by an excess of retrograde processes over those of growth; (3) That we must look to the inflammatory process, acute or chronic, for the explanation of the appearance and disappearance of these masses of tissue which before and even during exploration appear to be actual new growths. [T. M. T.]

3.—H. J. Garrigues, in the Dilatation of the Cervical Uteri in Obstetrical Practice, reviews the following methods: The drugs that are used consist of an ointment of belladonna smeared on the cervix, but, on account of the danger of infection, is very little used at the present time. A good substitute is atropine dissolved in sterilized water, injected into the tissue of the cervix in the dose of 1/40 grain; cocaine, 10% solution, painted inside and outside; chloral hydrate, grains xv, every twenty minutes for three or four doses; antipyrin, grains x, every half hour until three doses are given; strychnine, 1/30 grain, repeated every twenty minutes until 1/10 has been given. Quinine in 10 grain doses is also used. Ipecacuanha, grains ii, repeated every twenty or thirty minutes, is very excellent, although it is very disagreeable. The mechanical means are numerous, consisting of (1) tampons; (2) manual dilatation; (3) dilatable bags; (4) expanding metal dilators; (5) deep surgical incisions. The author favors manual dilatation, and says that a cervix toward the end of pregnancy may be so dilatable that in fifteen or twenty minutes it may be fully dilated. It is opened by pressure with the index finger and then dilated by lateral pressure exercised with the crossed thumb and fingers, using the flexor muscles.

[T. M. T.]

7.—H. A. Alderton gives certain systemic remedies in the above condition which seem to be beneficial, for example:

the iodide of potash in increasing doses. But the treatment *par excellence* consists of incision and evacuation of the tympanum, repeated if necessary and always accompanied by regular politerization and conscientious treatment of the nasopharyngeal condition. The relief is immediate, and while subject to temporary setbacks, permanent for the current attack. Before incision the external auditory canal should be made as nearly aseptic as possible by syringing with a tincture of green-soap solution, following this with instillation of absolute alcohol and then syringing with 1-2000 bichloride solution. The canal is then packed with aseptic gauze and the patient sent back to the waiting-room for half an hour to await the subsidence of the increased hyperemia necessarily induced by these procedures. The patient is then subjected to thorough cleansing of his nasopharyngeal cavities. The gauze packing is removed and under good illumination a thorough incision is made with a sterilized knife along the inferior segment of the drum membrane just internal to its attachment to the annulus. The ear is inflated and the mucus removed by means of sterile cotton pledgets. Finally, the canal is again packed with aseptic gauze, covered outside by a cotton pad kept in place by adhesive plaster. A mild astringent application of solution of silver nitrate or glycerite of tannis and carbolic acids is applied to the post-nasal mucous membrane. The patient must be seen in from twelve to twenty-four hours and the ear again gently inflated and the gauze packing renewed. After this, a treatment once in every two or three days is all that is usually necessary. Often the drum membrane may have healed by the first dressing. Should the exudate persist in reforming, a solution of nitrate of silver $\frac{1}{2}$ to 1 grain to the ounce of boiled distilled water acts favorably, both injected into the Eustachian tube and instilled into the tympanum through the incision. [T. M. T.]

7.—E. O. Bardwell, in the **Local Treatment of Gonorrhea**, states that the use of strong injections is uncertain, unsatisfactory and dangerous and should never be attempted; at any rate, in a first attack and in a mild case, using injections or irrigations of more than ordinary strength can do no good and is very likely to be productive of injurious results. He advises the use of copaiba and oil of sandal wood separately or in combination, especially in the first stage of gonorrhea. When copaiba cannot be tolerated, the use of spirits of turpentine, two or three drops in combination with cubeb in an emulsion, taken largely diluted, has seemed to have a beneficial action. It is well-known that if the above drugs can be given in large enough doses that they do some good, but they almost invariably derange the stomach. There appears also in all these cases an undue acidity and concentration of urine that requires the use of a mild, bland, uniritating diuretic, especially in the first stages of the disease, and for this purpose ten to fifteen grains of eltrate of potash will usually give good results. [T. M. T.]

THE NEW YORK MEDICAL JOURNAL.

September 21, 1901. (Vol. LXXIV, No. 12.)

1. The Lane Lectures on the Social Aspects of Dermatology. MALCOLM MORRIS.

CHARLES GREENE CUMSTON.
3. A Study of the Temperature, Pulse and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain. J. T. ESKRIDGE.
4. Conjunctivitis from X-rays; Incipient Retinitis apparently due to the same cause; Report of a case.
J. W. SHERER.

2.—C. G. Cumston, in his article on **Clinical Diagnosis of Carcinoma of the Esophagus**, states that gastrostomy may be effected under two different conditions. In the first

class, gastrostomy is performed at an early date in the course of the disease, while the patient is still able to take nourishment by the mouth, and when this is the case, the general rules of feeding after any operation may be carried out. Food by the mouth or directly through the gastric opening should only be given the day following the operation, progressively increasing the quantity at each feeding. In the second class of cases, and it is this class that the author has particularly in view, gastrostomy, for some reason or other, has been put off until late in the progress of the disease. In these cases the patients have not been able to swallow any food for a number of hours, and even liquids, which could previously be taken are rejected. The necessity for feeding is here an urgent indication. [T. M. T.]

3.—In **A Study of the Temperature, Pulse and Respiration in the Diagnosis and Prognosis of Certain Diseases of the Brain**, J. T. Eskridge states that the temperature in apoplexy is due to embolus or thrombus. In cases of hemorrhage into the brain substance unattended by hemiplegia, but in which the shock has been sufficient to cause loss of consciousness, there may be, and probably is, an initial depression of the bodily heat. In case of Ingravescient apoplexy the author has found the temperature slightly elevated, although he has seen two such cases within two hours after the patient first began to complain. Exceedingly high temperatures have been observed in hemorrhagic and other lesions of the lenticular nucleus. Apoplexy from a thrombus or an embolus is attended by only a slight variation of the temperature from the normal during the first two days. Exceptions are found in lesions of the pons and medulla. There is no perceptible initial lowering of the temperature; at least, the author has been unable to detect any. In the severest cases there may be a slight rise of temperature by the second day. In the vast majority of severe cases there will be a rise of temperature from the third to the fourth day. A rise of temperature at this time denotes softening. The lighter cases have no rise of temperature at any time, and the prognosis is favorable as far as life is concerned, and, to a greater or less extent for complete recovery. An elevation of two or three degrees above normal denotes extensive softening and renders the prognosis most grave. Cases in which the temperature remains above normal for weeks or months, although it may not go above 99°, will probably end in death from extensive softening. In the violent maniacs the temperature was nearly always slightly elevated above normal, and sometimes the thermometer registered 103° in the axilla. In the majority of melancholia cases the temperature is normal or slightly below. In the agitated melancholics the temperature frequently rises to 101° or 102°. A temperature two or three degrees above normal maintained in melancholia is of the gravest omen. The author has seen three cases in which the temperature ranged from 102° to 104°. They all proved rapidly fatal, only one running a course of four weeks. [T. M. T.]

BOSTON MEDICAL AND SURGICAL JOURNAL.

September 19, 1901.

1. The Use of Gynecology by the General Practitioner.
EDWARD REYNOLDS.
2. Movable Kidney; with Special References to its Consequences and its Etiology, Etc.
FRANCIS S. WATSON.
3. A New Factor in the Etiology of Visceral Pilels, etc.
AGNES C. VIETOR.
1. The Home (Sanitarium) Treatment versus the Climatic Treatment of Consumption.
VINCENT Y. BOWDITCH.
2. Eosinophiles as Constituents of Pus.
EDWARD T. WILLIAMS.

2.—Watson protests against the view too often held by medical men, that movable kidney is, with the rarest exceptions, a harmless condition. The condition sometimes results in such serious consequences as hydronephrosis

and pyonephrosis, in fixation in an abnormal position and in gangrene of the organ. The latter condition is produced by the occlusion of the blood vessels from rotation on the horizontal axis of the organ. The author reports 2 cases in which a previously movable kidney became fixed in an abnormal position. Both cases occurred in men; and in both the right kidney had become fixed on a level with the anterior superior spine of the ilium. He believes that nephropexy gives satisfactory results in the majority of cases; out of 6 cases that he operated on in his private practice, 4 remained permanently relieved. The author has noted that the position occupied by the kidneys in the recumbent position is from a half-inch to an inch and one-half higher than the position occupied by them in the upright position of the cadaver. By the examination of various cadavers he has demonstrated to his own satisfaction that the structures concerned in maintaining the normal position of the kidneys are those that form the attachments between the posterior and upper aspect of the tunica propria or perirenal fascia and the fascia covering the lumbar muscles and the peritoneum covering the diaphragm, aided by the less essential ones connecting the anterior surface with the peritoneum overlying it, and that any deficiency in the areolar tissue forming this fascia will lead to the development of movable kidney.

[J. M. S.]

3.—In a large number of cases of **visceral ptosis** the lumbar spine is in a condition of more or less marked lordosis, or, as is more frequently the case, it is more or less straight and is accompanied by lessened obliquity of the pelvis. This straightening of the lumbar spine and lessened obliquity of the pelvis, Victor believes, is both a cause and an effect of visceral ptosis. She describes the changes brought about in the abdominal viscera by the development of the young woman and the influence exercised on these organs by the adoption of corsets and long skirts and by the first pregnancy. She concludes that the treatment of ptosis should begin in infancy and should never be lost sight of at any age. She describes a corset for visceral support. [J. M. S.]

4.—Howditch defines his position concerning the **home (sanitarium) treatment versus the climatic treatment of consumption**. 1 From his own experience in New England he is strongly in favor of the erection of sanatoria for the treatment and cure of consumption wherever that disease prevails. 2 He does not think that we are in a position to judge fairly at present the relative results to be obtained by this method in favorable or unfavorable climates. 3 At present he thinks that better results can in all probability be obtained by this form of treatment in the western sections of the country than in the eastern sections.

[J. M. S.]

5.—Williams has found **eosinophile leukocytes** in every specimen of **pus** examined, in large proportion. He believes that the granules are precipitates of the cellular protoplasm. If these observations are correct it is clear that the eosinophile cell can no longer be called a specific cell. It is a purely pathological product, resulting from a natural alkaline decomposition of the body of a common leukocyte. In other words, it is a necrotic cell. [J. M. S.]

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

September 21, 1901.

1. A Method of Teaching Relational Anatomy.
C. M. JACKSON.
2. The Aim of Medical Education, and its Relation to Research Work by Medical Students.
W. S. CHRISTOPHER.
3. Necessity of a Practical Knowledge of Dietetics, Hydrotherapy and Physio-Mechanical Therapeutics, Etc.
FENTON B. TURCK.
4. The Seminar Method in Medical Teaching.
BAYARD HOLMES.
5. Medical Education. J. R. JONES.

1.—Jackson has worked out the following plan for instruction in **relational anatomy**. Hardening of cadavers by the injection of 50% formalin solution into the arterial system; study of surface form, laying special stress upon

land marks, etc.; making of sections through the body in planes separated by short intervals and carefully studying and making drawings of these sections; a search of literature for points involved and a carefully written report of the results obtained. [F. T. S.]

2.—Christopher directs our attention to the aim of medical education and particularly its relation to research work by medical students. He contends that research work should be undertaken by the medical man when his experience has become sufficiently ripe for him to determine his own problem. This line of investigation should not find a place in the short and well occupied medical course of to-day. [F. J. K.]

3.—Turck discusses the necessity of establishing a course of instruction in dietetics, hydrotherapy, and physio-mechanical therapeutics, in the medical curriculum. The sentiment voiced by the medical institutions in the United States seems to be in favor of establishing courses in these subjects. [F. J. K.]

4.—Holmes says that **seminar** is a method in which each member of the class does independent laboratory, clinical or library work, on a sub-topic of general interest to the class, this sub-topic being chosen by the student or assigned by the teacher. It is a meeting of the students and teacher to criticize the work of individuals. The seminar presupposes an elective course; in no other way can a student have time for exhaustive study. The student must also have a preliminary literary training and an ability for research work. [F. T. S.]

5. The Lane Lectures on the Social Aspects of Dermatology. No. II. MALCOLM MORRIS.
6. Intraspinal Cocainization, Etc.

BURDETT ATKINSON TERRETT. (Concluded.)

1.—Beyea mentions the great frequency of **floating kidney** in women and the fact that the suffering induced by it is often treated as indigestion, hysteria, etc. From his own experience he would give ten or fifteen per cent. as the proportion for floating kidneys producing symptoms. He classifies pathological mobility of the kidney as movable kidney, floating kidney, and floating kidney with enteroptosis. The treatment is medical, mechanical, or surgical. The movable kidney without symptoms needs no treatment or needs measures directed towards the condition of the general health. If it produces symptoms it should be treated mechanically by the application of a simple elastic binder which supports the lower two-thirds of the abdomen, of the application of a long, straight front, modern corset. The ordinary kidney pads are not only useless but harmful. Cases with severe and persistent symptoms should, in the well-to-do, be placed on medical treatment and the kidney be maintained in position by a mechanical support. If this fails nephropexy should be performed. In the poor it is best to resort at once to nephropexy. In cases complicated with enteroptosis, particularly gastropexy, nephropexy and mechanical supports give much relief, but the treatment of the future is nephropexy followed later by the operative shortening of the gastric hepatic omentum and the gastric phrenic ligament. In an operation for holding the kidney in place direct injury to the parenchyma or capsula through cicatricial change as must occur in suturing, the Senn and Deaver operation, and any capsule splitting operation, should be avoided. The principle sought in the Harris

operation is the correct one. Heyea proposes the following operation which was first planned and practiced by Dr. C. B. Penrose: A longitudinal incision is made in the lumbar region for a distance of three and a half inches; the perirenal fat is exposed and excised, opening the space of Gerrotta; the kidney is then delivered and a point at the hilum of the kidney in the perirenal fascia, which is free from blood vessels, and about 1 cm. above the ureter and renal vessels, is perforated by a rubber drainage tube of sufficient length to surround the kidney and protrude from the wound. A second tube is introduced below the ureter and vessels and brought out of the wound in a similar manner. The drainage tubes being surrounded by the perirenal fascia are prevented from changing their position and slipping over the convex end of the kidney or from interfering with the ureter or vessels. The kidney is now replaced and the wound closed, leaving a small opening for the tubes. A piece of gauze is placed over the wound and the rubber tubes tied. At the end of ten days the sutures are removed; the tubes are allowed to remain in for three weeks, forming two connective tissue cords which support the kidney. This operation has been performed in eight cases, three of whom were operated upon two and a half years, three two years, one one year, and the other six months ago. All have been examined recently and in all the kidney is fixed in position. [F. T. S.]

2.—Injuries to the thoracic duct occur as the result of disease as tuberculosis or cancer, from serious traumatism like fracture of the spine, and from accidental and operative wounds of the neck. Two cases are reported. One followed the removal of tubercular glands from the neck and was recognized by a sudden spurt of greyish-white material into the wound. The torn duct was stitched with fine cat gut and a small amount of gauze packed over the point from which the fluid had escaped. No subsequent leakage occurred. The second case occurred during an operation for the removal of carcinomatous glands, and was not recognized until after the operation, when the discharge became chylous. This finally ceased. A résumé of 15 other cases is given, of which two only were due to accident and thirteen to operative injury. The authors next review the anatomy and physiology of the duct and analyze the reported cases. In six of the cases injury to the thoracic duct was not suspected at the time of operation, while in the remaining eleven cases it was known to have occurred. The subclavian vein was injured in two cases and the internal jugular in two cases. The discharge of lymph when it occurred at the time of operation was slight in two cases, moderate in five, and quite profuse in four. The treatment of the 11 cases where the injury was recognized at the time of operation was by packing, suture, and ligation. Packing was employed in five cases, suture in four, and ligation in one. The cases, that were packed, with one exception continued to discharge from the first. In the cases in which suture was employed leakage occurred in two. The case of ligation showed no leakage. Secondary operation was resorted to in three instances, the leaking point being clamped in two and ligated in one. Constitutional effects from the lymphatic discharge was seen in three cases. Only one death is recorded. The value of packing in the treatment of these wounds is unquestionable but it must be accurate and firm. After operation the nourishment should consist solely of proteids and all fat should be avoided, thus reducing the material passing through the thoracic duct to a minimum. The authors suggest inducing the absorption of fat during operations in the neighborhood of the thoracic duct in order to guard against its injury. Four to six ounces of cream should be given about three hours before operation. In case of injury of the duct it should be sutured with fine silk or catgut if possible. All discharging lymph radicals should be ligated unless they be of considerable size, when the ligation should be delayed until the integrity of the thoracic duct is demonstrated. When suturing is impossible gauze packing should be applied. The head and neck should be kept at rest and morphine used if necessary. [F. T. S.]

4.—Leon L. Solomon treats of the therapeutic value of alcohol, and goes over the ground emphasized by others who advocate its use in medicine. He emphasizes the point that alcohol must be in a state of dilution before it can be absorbed. He concludes that by using it in its

proper therapeutic application, the utmost discriminating judgment and extraordinary care are necessary. [T. L. C.]

6.—Terrett gives a summary of the literature of medullary narcosis as applied to general surgical procedure without adding anything especially new. [F. T. S.]

9.—Robert Willson discusses the practical and scientific value of the blood examination to the medical man and surgeon. The article is to some extent a reply to Dr. John B. Deaver's recent contribution on this subject to the Philadelphia Medical Journal. [T. L. C.]

VRATCH.

June 9, 1901. (XXII, No. 23.)

1. From Clinical Lectures. PH. K. GEISLER.
2. A New Modification of the Bandage for Fracture of the Clavicle. M. G. TCHERNIACHOVSKI.
3. A Case of Gaseous Sub-diaphragmatic Abscess (Pyopneumothorax subphrenicus, Abscès gazeux sous-diaphragmatique). N. D. STRASZESKO.
4. The Treatment of Ulcers by Caution. G. I. A. TARABRIN.
5. Abas-Tuman as a Climatic Station, from the Standpoint of the Mode of Life. P. L. ABRAAM.

1.—Geisler reports in one of his lectures, delivered before the students of the Military Medical Academy on a case of primary malignant disease of the left lung, in a man 43 years old, presenting obscure thoracic symptoms. The differential diagnosis was to be made between aneurysm of the aorta, pulmonary tuberculosis, actinomycosis, pleurisy, syphilis, malignant disease and, possibly, echinococcus. A careful analysis of the symptoms led the author to the conclusion that the case was probably one of primary malignant disease of the left lung. The patient died, and the autopsy revealed a lympho-sarcoma of the left lung, with metastasis into the lymphatics of the anterior mediastinum and the liver, tubercular foci in both lungs, pleuritic adhesions, emphysema and bronchiectasis. [A. R.]

2.—The description of the new bandage can be best understood by referring to the illustrations which accompany the original paper. [A. R.]

3.—Straszsko reports a case of subdiaphragmatic abscess in a man 38 years old. The patient was loading timber, when he suddenly experienced a sharp pain in the right half of the abdomen. This was followed by nausea and vomiting and a gradual development of a swelling in the epigastric region. Percussion over the swelling elicited a mixed tympanitic and dull sound, indicating the presence of gas and fluid. By means of a hypodermic syringe a little of the fluid was removed at the seventh intercostal space, and was found to be thick, ill-smelling pus. A bacteriological examination revealed the presence of streptococcus and a bacillus belonging to the colon group. An operation was performed, but the man died from catarrhal pneumonia and exhaustion. The autopsy showed no perforations of either stomach or intestines which could account for the formation of the abscess. The supposition is made that, under the strain of lifting heavy timber, a hemorrhage took place between the liver and the diaphragm, followed by the invasion of the streptococci and colon bacillus, which were the factors in the formation of the abscess and the production of gas. [A. R.]

4.—Tarabrin recommends the following method of treating ulcers: A Paquelin cautery is heated to redness and the point of the cautery kept at a distance of 5 to 6 cm. from the ulcer. If no pain is experienced the distance is shortened to 3 or 2 cm. Having found the distance which causes the least pain, the cautery is applied for two or three minutes. The ulcer is cleansed before each sitting, and covered with cotton and any dusting powder after it. The treatment is repeated every day or every other day. The author employed this method in 11 cases of soft chancre, 4 of bubo, 2 of chronic ulcer and 1 of indolent ulcer, with the following results: One case of chancre was cured after 2 sittings, 2 after 3, 4 after 4, and 4 after 5; 1 case of bubo was cured after 9 sittings, 1 after 10, 1 after 12 and 1 after 15; 1 case of chronic ulcer was cured after 11 sittings and the other after 16. An indolent ulcer of fourteen months' standing was cured after 19 sittings. The suggestion is made that this method may also prove useful in the treatment of lupus, rectal fistula and any other forms of ulceration. [A. R.]

Society Reports.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fiftieth Annual Meeting Held at Philadelphia, September 24-25, 26th, 1901.

FIRST DAY.

The Society convened at Horticultural Hall and was called to order at 9.30 A. M. by the President, Dr. Thomas E. Davis, of Pittsburg. After a short address Dr. Davis called upon the Reverend Henry C. McCook, D. D., who made the invocation. The register of delegates was then presented by the secretary, Dr. George Erety Shoemaker, President of the Philadelphia County Medical Society, next welcomed the organization to Philadelphia, followed by Mayor Ashbridge of Philadelphia who welcomed the delegates to the city. The morning session was devoted to the report of committees, and the presentation of resolutions deploring the death of President McKinley, and containing a condemnation of anarchistic doctrines, the resolutions being adopted by a rising vote. The Secretary's report showed that the present membership had increased 110 during the year. The State Board of Medical Examiners deplored the illiteracy which existed among candidates for licenses to practise medicine. The Committee on Pharmacy recommended resolutions against furnishing medical attendance and free medicine to many patients who are well able to pay for the same.

Afternoon Session.

The first paper read in the afternoon session was the *Address in Otology*, by Dr. E. U. Buckman, of Wilkesbarre, Pa., who after reviewing some of the progress that had been made in aural surgery, referred especially to the performance of incudectomy in progressive failure of hearing. Regarding mastoiditis he believes that abortive treatment usually fails. The mastoid cells are more or less involved in middle ear disease; but whether the mastoid is involved or not operation should be prompt and complete, even if there is apparently but little involvement of the mastoid cells, the danger with operation then becoming practically nil. The treatment of mastoid disease is now one of the most satisfactory procedures in otology. Speaking of the symptom of tinnitus aurium, Dr. Buckman's observations show that the patients frequently complain more of noises than of deafness. He has not been able to definitely determine the cause of this symptom either from literature or from personal observation. In many cases there are strictures, sometimes of the eustachian tube with the consequent prevention of the ventilation of the ear, and the interference with free vibration. The treatment has been the introduction of bougies and artificial ventilation by means of inflation, but the author has always feared that the bougies would break off, and furthermore they do not cure the strictures. He has found massage of use in his cases, but he emphasizes that it must be kept up for some time. He has employed electricity, especially in obstructive cases resisting treatment, having employed Kennedy's method for a period of four months. On account of this brief period of observation absolute conclusions have not yet been drawn by him, but he believes that Kennedy's claims are not extravagant. The syringe, a most useful appliance in the treatment of ear disease, is very valuable, when used in suitable cases.

Some Aural Complications of Influenza was the subject of the paper by Dr. S. MacCuen Smith, of Philadelphia. After a review of the epidemic and pandemic invasions of influenza, the author stated that the disease is not so much feared per se as are its local complications. He believes it hard to draw a clinical picture of the changes caused in the upper passages, with the exception of one condition, namely, hemorrhagic otitis, supposed by many to be the chief symptom of influenzal otitis. There is no doubt that this condition occurs in these regions as in other tracts, notably, the gastrointestinal, and the genitourinary passages. After discussing the quickness and virulence of this form of complication the following symptoms are mentioned: Severe myringitis, hemorrhagic

in character, with bluish extravasations that tend to coalesce, and which as Politzer states, also tend to collapse and discharge a serosanguinous fluid before rupture. In many cases there is mastoid involvement, and an unusual large number of cases require operation. The pain is usually alleviated in ordinary cases when the fluid is evacuated. But in influenzal otitis the pain continues, and one should be on his guard for lateral sinus thrombosis, intracranial and extracranial abscesses, and meningitis. The demonstration of the exciting organism is important, but in a short time a mixed infection results by the invasion of staphylococci and streptococci, which supplant the germ of influenza. It is a mistake to determine the virulence of such conditions by the odor or chronicity of the discharge, for nonpathogenic cases may retain an odor; hence the value of microscopical examination. Of 23 cases reported by the author 9 were distinctly hemorrhagic; in 11 the tympanic membrane ruptured spontaneously in 42 hours with a continuance of the fever and mastoiditis; in 6 the membrane was freely incised before the time of spontaneous rupture, relieving pain and decreasing temperature; meningitis was present in 2 cases before operation, and one case suffered severely from otitis before rupture. Regarding the treatment Dr. Smith called attention to prophylaxis which is familiar to all. He advocates as treatment absolute rest in bed, properly conducted diuresis, mild and restricted diet, a two to three day fast sometimes doing more good than all other procedures together. For the influenzal earache the instillation of a hot boric acid solution will do no harm, and may even be palliative, but as a rule hot drops do very little good; when they do prove efficacious the good results are to be attributed more to the influence of the heat than to medication. (This paper will appear later in the Philadelphia Medical Journal.)

Dr. Charles H. Burnett in discussing Dr. Smith's paper stated that he had never seen any symptom in influenzal involvement which he had not seen in other cases of mastoiditis, and whatever treatment is of use in these cases is also of use in the condition under discussion. He called attention to the fact that in measles there are also swelling and hemorrhagic spots, and he did not see how there was anything specific in influenza as an exciting factor of middle ear disease.

Incudectomy in the Treatment of Progressive Hardness of Hearing, Tinnitus Aurium and Ear Vertigo, by Dr. Charles H. Burnett, of Philadelphia. The speaker believed that progressive hardness of hearing was the result of a trophoneurosis, and not a purely catarrhal process, notwithstanding that it cannot be denied that one does sometimes meet catarrhal progressive hardness of hearing. In the cases under discussion the tympanic membrane is usually found more retracted than in ordinary changes, such as for instance the hypertrophic ones. In describing attacks of ear vertigo, which in the majority of cases depend upon a chronic sclerotic otitis, the author stated that they may be monolateral, although both sides may be affected. He calls attention to the differential diagnosis between ear vertigo and epilepsy. The sudden vertigo and tinnitus aurium which may last for a few minutes to a half-hour, causing the patient to take hold of some object or to sit down, usually without vomiting and nausea at the first attack, and which may result later in collapse, but without loss of consciousness, are important diagnostic points. The patient reels toward the affected side, and if both sides are affected the patient cannot walk and his condition is frequently confounded with alcoholism. He calls attention to the employment of the term "Meniere's symptom" and not "Menier's disease" to this symptom-complex. The first attack is usually light, and attributed to gastric derangement, and treated as such. The second seizure may not come for a short time, but then they increase in frequency; and still the true cause may be overlooked. The surgeon should be on his guard to overcome the retractive power of the tensor tympani, as surgical interruption in these cases often arrests the progressive hardness of hearing.

A Few Reasons for Early Operation in Acute Mastoiditis, by Dr. Wm. H. Dudley, of Easton, Pa. The author of this paper believes that the medical profession as a whole has not yet seemed to grasp, that acute mastoiditis is dangerous unless operated on early, and quoted a case of mastoiditis followed by meningitis, which was attributed by the author as being directly due to delay in operative inter-

ference. The various symptoms and indications for operation were discussed. In discussing this paper Dr. A. Randall, of Philadelphia, stated that no one statement will cover the ground regarding operative interference. While several hundred cases may be reported without operation, and another few hundred that had to be operated upon, a hard and fast line, nevertheless, could not be drawn. Many cases are not due to caries of the mastoid, and do not need operation. A great many clear up under proper measures of medication, rest and hygiene. He believes that a serious error will be made if we do not realize that many cases exist, not in the sense that bacteria have penetrated, but that the condition is concurrent with the middle ear affection, and would result fatally even with operation. Dr. Chas. H. Burnett, when asked concerning the diagnostic points that indicate operation, replied that they are pain, pyrexia, and prolapse of the drum membrane.

Some of the Ocular Affections of Childhood Associated with Impaired General Nutrition, by Dr. S. D. Risley, of Philadelphia. Dr. Risley quoted several cases as illustrating the ocular involvement that may be present in affections of childhood associated with impaired general nutrition and derangement of metabolism. One case was that of a child who complained of a blurring of the page while reading, red eyes, and tenderness, and in whom a high hypermetropic astigmatism was present. After correction of the refractive error, the child returned with petit chorea. Examination showed that the refractive error had now changed from a hypermetropic astigmatism to a myopic astigmatism; the disks were overcapillary, and their edges indistinct on account of hazy retinal fibers; there were areas of absorption in the fundus, and granular changes in the macula and between the macula and the disk; the tonsils were hypertrophied; the turbinates were boggy; the urine was high colored, and of a specific gravity of 1028, but without sugar; there was intermittent albuminuria. Under a strict hygienic regime the eyes improved, and the eye changes gradually disappeared, all that was left being the absorption signs. The other case was that of a girl of 11 years of age with acne, dry and yellowish white hair, and a listless and apathetic manner. The turbinates were boggy. There was photophobia, the caruncles were swollen, the retrotarsal folds thickened, and both the bulbar and palpebral conjunctivae were congested. The vision was 6/12. Ophthalmoscopic examination showed a swelling of both nerves, the edges of the disks being hazy, the veins large and dark, and areas of pigment absorption, especially between the nerves and the macula. There was a low hypermetropic astigmatism. The visual fields for form were concentrically contracted, and the color fields reversed as in hysteria. Small quantities of albumin were found in the urine. Under a general treatment consisting of tonics and alteratives the general condition gradually improved, the reversal of the color fields increasing, but at no time reaching the normal. At 12 years of age a scanty menstruation occurred, causing an exacerbation of the ocular symptoms at each menstrual period. The hypermetropic astigmatism now changed to a myopic astigmatism. Dr. Risley believed that much unnecessary punishment is inflicted in children with apparent ungovernable tempers and allied conditions, on account of overlooking such manifestations. Each of his cases were characterized by symptoms of faulty metabolism such as headache, general malaise, precarious appetite, variable temper and the asthenic symptoms. He believes that the stretching of the eyeball would not have occurred as readily in the absence of the faulty metabolism.

Gumma of the Ciliary Body.—By Dr. Edwin Stieren of Pittsburgh, Pa. is of the opinion that syphilitic involvement of the deeper ocular structures, especially in the acquired form usually calls for a guarded prognosis. He reports the case of a woman aged 20, with a negative family history, but in whom when first seen a diagnosis of tertiary syphilis was made. The patient later presented herself with a deeply seated and spreading ulcer involving the cartilaginous septum of the nose and the upper lip. In spite of large and rapidly ascending doses of potassium iodide ocular involvement set in one week later, consisting in extreme photophobia, marked ciliary injection, discoloration of the iris, cloudy aqueous humor, followed by extensive leukocyte hyphema, and a small pupil which was inactive. The usual treatment for iritis, consisting of hot fomentations, the instillation of atropine solution, large

doses of potassium iodide, and $\frac{1}{4}$ gr. calomel every hour, was instituted. A diagnosis of gumma of the ciliary body was made later, the tumor being of a purplish color, symmetrical in outline, and intensely painful on the slightest pressure. The pain became more acute and constant, ciliary injection more intense, and vision destroyed up to light perception. The cornea soon became hazy, preventing even a fundus reflex from being observed. Under extremely large doses of potassium iodide a paralysis of the right external rectus muscle, which had existed, now disappeared, resulting in a perfect excursion of the eyeball in all directions. All that was finally left of the gumma was a slaty discoloration of the sclera, the misplacement of the pupil, and some fine deposits at the periphery of the anterior capsule of the lens. Under proper refraction fairly good vision was obtained. He believes that such cases do not call for a hopeless prognosis, even if vision is considerably reduced, potassium iodide even doing good where a disorganization of the vitreous has occurred; but there is no accurate dosage of the drug in such cases, as it should be pushed until visible signs of improvement are obtained.

Contagious Disease of the Eye and Their Treatment.—By Dr. S. Lewis Ziegler, of Philadelphia. The speaker reviewed the treatment of pink eye, trachoma, ophthalmia neonatorum and other contagious disease of the eye. He believes that it is safe to regard every discharge from the eyeball as contagious and treat it as such.

Address in Mental Disorders. Paresis from the Standpoint of the General Practitioner, by Dr. Robert H. Chase, of Philadelphia. The speaker stated it is a mistaken idea of the family physician to believe that only the specialist is to observe and treat this treacherous affection, which is really first encountered by the family physician himself, it being a mental breakdown of middle life. Early treatment is necessary to stay its progress, and its complexity may be appreciated when we consider that throughout its course there is no mental function which is exempt from its ravages. The dominating symptoms may be either cerebral, bulbar, or spinal in character, but many observers are of the opinion that the cerebral cortex is that portion which is primarily involved. The literature on the subject, and especially regarding prognosis, was freely consulted. He called attention to the symptoms which are of the greatest value, namely, the tremor, the uncertain gait, the pupillary phenomena, the weakened intellectuality, and the delusions of grandeur. He called attention that during the initial stages of the affection there is not a uniform progression of the symptoms, as is also the case in many other neuritic affections. The different forms that the disease may assume are of importance, as they may be dementive, expansive or depressive. The symptoms were then more thoroughly discussed, as well as the physical signs, the latter being indefinite, as they may indicate neurasthenia with or without hysteria, or cerebral asthenia. The author quoted the exhaustive therapeutic measures that have been instituted against this affection. The treatment in the early stages must be directed toward the causes and their removal. Cofion, alcohol, worry and strain, should be avoided, and both physical and mental work reduced. Hygienic principles should be rigidly observed. The diet and the bowels should be looked after, and in selective cases hydrotherapy and electricity may be of avail. The specific manners of treatment were then individually discussed. Especial attention was called to the frequent futility of prolonged travel with its attendant inconveniences and excitement, although a change of surroundings is indicated; should the latter interfere with salary, etc., a reduction in the amount of work is imperative. The speaker exhorted the practitioner to keep in mind his duties as a conservator of public health and his duty to take part in the eradication of hereditary tendencies. While this is more imperative in other forms of insanity, paresis nevertheless leaves its stamp on succeeding generations with unremitting force. (This address will be published later in the Philadelphia Medical Journal.)

Two Cases of Progressive Muscular Dystrophy in Brother and Sister.—By Dr. A. A. Eshner, of Philadelphia. The first case reported was that of a boy aged 14, presenting the typical picture of progressive muscular dystrophy of the hypertrophic variety. The family history was particularly interesting, as a sister of 32 was also afflicted with the same disease, and in a more advanced stage. The

father, aged 70, when a boy, had fallen and struck his head, requiring trephining. The father had three sisters, all of whom were living, and weighed between 225 and 300 pounds each, and a fourth sister, who is dead, had weighed 250 pounds. Nearly all of the 15 children had been inordinately large. Of 20 cases reported by the author, the disease existed in only two in the same family. He quoted the cases of Gowers where, among 118 cases, the affection involved 39 families, Gowers even quoting a case where 8 brothers were affected. The disease first appears in the first decade of life; in the author's 20 cases it was present in 2 at birth, in 8 cases during the first five years, and in 10 cases during the second 5 years. It is more prevalent in males, 16 of the author's cases being males. It is rare in the negro, if it occurs at all. The essential lesion consists of a degenerative change in the muscle fibers with more or less hyperplasia. The etiology is obscure. He quotes a case where in addition to the muscular changes there were changes in the anterior cornua of the spinal cord. Regarding treatment he has found thyroid and thymus extracts of little or no value. Massage may be tried. When deformity occurs tenotomy may be justifiable. Intelligently conducted exercise is of value. (This paper will be published later in the *Philadelphia Medical Journal*).

The Use of Hyoscine in the Treatment of Chorea.—By Dr. W. Brown Ewing, of Pittsburg, Pa. In the absence of the author this paper was read by title.

Prognosis in Neuritis.—By Dr. F. Savary Pearce, of Philadelphia. Dr. Pearce believes that there are signs and symptoms of neuritis which are indicative of its probable ultimate result. Pressure neuritis is to be distinguished from the occupation neuroses. Pressure neuritis per se will, as a rule, recover with massage and galvanism within a few months, but its liability to relapse should be considered and the patient so informed. Septic cases are usually favorable after eradication of the primary seat of infection. He calls attention to suppurative cases of Pott's disease, which are seldom followed by complete paresthesia. Stablemen seem to be especially liable to neuritis. The prognosis of alcoholic neuritides, and also those caused by metallic poisons depends upon the frequency and gravity of successive attacks. Diphtheritic neuritis is apt to be fulminant, and according to the author is worse in cases that have been treated with antitoxin. Chronic gastrointestinal disturbances are liable to cause neuralgia, which is often the forerunner of neuritis. The lithemic, rheumatic and gouty diatheses give rise to local neuritis, due to the imperfectly oxidized aggregation of by-products. The author has had more success in treating rheumatic neuritis with drugs than any other form. Regarding neuromata, he reports a case of chronic sciatica due to a neuroma involving the plantar nerves, there being no pain, however, in the tumor itself. Gonorrheal neuritis is usually local, and, according to the experience of the author, is confined to the anterior tibial region.

The meeting then adjourned, and was followed in the evening by the annual address, which was delivered by Dr. Thomas D. Davis, president of the Medical Society of the State of Pennsylvania, who gave a historical review of the pioneer physicians of Western Pennsylvania, among them being Gen. Hugh Mercer, Arthur St. Clair, Edward Hand and William Erwin, of the Revolutionary Army. A reception by the Philadelphia County Medical Society of the State of Pennsylvania, guests and visiting ladies, in the foyer of Horticultural Hall, then closed the programme of the day.

(To be continued.)

A Massive Carcinoma of the Liver.—Landrieux reported a case of massive cancer of the liver in a woman of 66, who died two days after admission to the hospital. 5 months ago ascites first developed. Jaundice appeared four days before admission. She was emaciated, slightly jaundiced, with marked edema of the legs and ascites. There was acholuria, and the bowel movements were clay colored. Landrieux had diagnosed gastric cancer with metastasis to the liver. She died in coma. The autopsy showed a massive primary carcinoma of the liver. The gall-bladder was white in color, and no bile existed. There was absolute acholia, the main symptom of massive carcinoma of the liver. (*Bulletin Medical*, June 12, 1901, No. 46). [M. O.]

TWENTY-NINTH ANNUAL SESSION OF THE AMERICAN HEALTH ASSOCIATION.

The American Public Health Association held its 29th Annual Session in the Armory of the 71st Regiment, Buffalo, N. Y., September 16-20, the principal topics for discussion being tuberculosis, yellow fever and the re-establishment of the army canteen. An appropriate memorial meeting, upon the death of our beloved President, was also held, at which fitting resolutions and addresses were presented.

"Report of Committee on Animal Diseases and Animal Food." Dr. D. E. Salmon, Chief of the Bureau of Animal Industry, Washington, D. C. The doctor referred to the extent and rapid increase of bovine tuberculosis in various countries during recent years, and that this fact should cause alarm, irrespective of the question of direct communicability of tuberculosis from animal to man. The consumption of food thus infected has always been considered harmful. Even if Koch's theory were correct, and even if it were admitted that it is not essential to adopt measures against this disease in cattle in its relation to infecting human beings, there is nothing plausible in the belief that the products of these diseased animals are harmless and should be allowed to be consumed. This should not permit of any influence towards the non-condemnation of infected meat, but it does seem as if already Koch's theory has been allowed to stand as an excuse for the dissemination of tuberculous, diseased products. Dr. Koch had made two assumptions: 1. That human tuberculosis differs from bovine tuberculosis and cannot be communicated to cattle. 2. Mankind is insusceptible to bovine tuberculosis. Dr. Salmon does not give to Dr. Koch the credit of any originality in his hypotheses. "The Bureau of Animal Industry has distributed hundreds of thousands of doses of tuberculin made from human bacilli, and this tuberculin has been used by State authorities in various parts of the United States for diagnosing the disease of cattle, and has been found extremely reliable and satisfactory for this purpose. There is no contagion which affects so many and such widely separated species of animals as does the bovine bacillus and which is not at the same time pathogenic for man. Bovine tuberculosis is communicable to horses, cattle, sheep, swine, dogs, cats, guinea pigs and rabbits. This is a very extensive range of pathogenic power. What other pathogenic germ is there which is virulent for so many and such widely separated species and which is not virulent also for man? Surely a germ which is pathogenic for so many species of animals as is the bovine tubercle bacillus should be considered as a germ dangerous to man until positive evidence has proved its innocence." The Doctor then takes up a further discussion of the subject under four different heads: 1. Accidental inoculations with bovine bacilli. 2. Clinical evidence of individuals infected with milk. 3. Statistics of intestinal tuberculosis. 4. Results of post-mortem examinations.

Dr. Jesus Chico, Jalisco, Mexico, spoke upon the effect on the internal organs of eating tuberculous meat, and in referring to the transmissibility of the disease from infected animals, cited several cases. A healthy stage driver and his wife, who were both previously healthy, had eaten of the lungs of a tuberculous cow. In a little more than a year out of a family of seven, five had the disease.

"Tuberculosis" was the subject of a paper by Dr. Felix Formento, (New Orleans). The Doctor prefaced his paper by stating that while he did not for a moment deny the importance of bacteriology, yet the study of man in health or disease is often sacrificed to that of the infinitesimal microbe. He believed that the discovery of the bacillus of tuberculosis was one of the events of modern civilization, it has demonstrated that the disease is communicable from man to man and from animals to man; it has shown that

the sputum of consumptives, loaded with tuberculous bacilli, is the great carrier of infection, and that one of the first steps for the eradication of the disease is the destruction of the sputum and everything that may have been contaminated by its contact. The author asked whether the profession is not going too far in preaching the erroneous doctrine that heredity plays no part whatsoever in this transmission. The neglected factor is: Heredity or predisposition or, in other words, the soil necessary for the development of the germ. Heredity does play a powerful part and this has been demonstrated already, for numerous instances could be cited showing the influence of heredity. Some cases of direct transmission of tuberculous to the fetus in the utero have been observed. Who has not known families in which tuberculosis was plainly hereditary for several generations? Dr. Fannig, of Norwich, recently declared at the London meeting that 52% of all cases treated in private sanatoria in England descended from tuberculous parents. The air swarms with microbes; those predisposed alone succumb. Whether heredity transmits directly the disease or furnishes a soil which renders the subject most liable to the least exposure, the result is the same. In both cases tuberculosis should be considered as hereditary. In order that the seed may properly develop, two conditions are required—a live, active seed and a proper soil. The same is true of a diseased germ, whether the proper soil be found in the living organism or in the special conditions of a locality. Predisposition is not always hereditary. It may be acquired. All debilitating causes, unhealthy trades and occupations, want of pure air and sunlight and insufficient alimentation affect nutrition and predispose the strongest men and children alike to the ravages of tuberculosis. Low, damp, dark, badly ventilated houses render persons living in them more liable to contract the disease by lowering the system, by diminishing its power of resistance; they are, at the same time, a most favorable *nidas* for the development of the bacillus. The abuse of alcoholic drinks is a powerful predisposing cause to the disease. The Doctor strongly advocated as the means of exterminating the disease the destruction of the sputum, the disinfection of rooms occupied by consumptives, and likewise a most rigid inspection of the milk and meat, in spite of the most recent claims of Koch. In this connection it may be said that the theory advanced by Koch, that bovine tuberculosis is different from human tuberculosis, so much so that it cannot be transmitted from animal to man, has not been accepted by the scientific world. The author urged that international measures be adopted to disinfect steamers, railroad trains, hotels, etc., and the enforcement of all known laws of public and private hygiene. In order to carry out all necessary prophylactic measures, the first condition is a law or ordinance requiring that all case of tuberculosis be reported to the proper authorities.

Dr. Frederick Montizambert, of Canada, was then called upon to present his report of the International Congress on Tuberculosis which convened in London recently. He very interestingly recited incidents in the proceedings, which are so well-known to the readers of this journal, through its extensive reports of the Congress, that they do not bear repetition.

Dr. E. A. de Schweinitz, of Washington, was called upon to open the discussion. He referred to the excellent paper of Dr. Salmon, which so thoroughly covered the subject that there was very little left for him to say. In speaking of tuberculin, he said that tuberculin—solution of the products of the tuberculous germ—which will produce characteristic reactions in tuberculous cattle, as well as in men who are tuberculous, can be made and is made, to a very large extent, from human germs, which is perfectly innocuous when injected into the animal body.

Dr. P. H. Bryce reminded his hearers that through the insufficiency of the legislation in the matter of governing the milk supplies of our cities, we are constantly facing an increase in tuberculosis in children, and also the pres-

ent danger of the transmission of such diseases as scarlet fever, diphtheria and typhoid through infected milk from cattle.

Prof. Brewer, suggested whether there was not a change going on in the physiological or anatomical structure—if the bacillus can have any anatomy—of the culture, while its chemical functions remain essentially the same. He claimed that our knowledge of the chemical products of bacteria is wonderfully meagre compared with its importance, and that our bacteriologists study bacteria hardly from the chemical side.

Dr. A. C. Abbott said that during the last few years the conceptions of the bacteriologist and the lines of work followed by him have been fundamentally lines concerning the important question of variation, and particularly lines of work in which chemistry has played an important part.

Dr. Sehriener said that perhaps while we do not all agree with that great light on tuberculosis—Dr. Koch—still what he did say may result in great good, for the very reason that we will continue to investigate this subject more thoroughly and more effectively than we would have done if he had not delivered that address and made such startling statements to the world. Therefore, let us continue an investigation of this great subject.

Dr. Chapman thought that we were teaching too much that tuberculosis was non-hereditary. He believed that there is a tendency in every one who comes of a tuberculous family to heredity and tubercular taint.

Dr. Gibson said that he was not prepared to accept the statement, that he had seen enough to satisfy him that human and bovine tuberculosis are identical, or virtually so, and that they are transmissible.

Dr. Durgin said, in speaking of the care of the tuberculous subject, that he believed in placing and holding him intact from the rest, in order to prevent spreading of the element of infection, and that there was no reason why they should not be isolated the same as smallpox and scarlet fever.

Dr. Wm. Foster Smith, Executive of the Superior Board of Health, of Puerto Rico, said that neither the Board nor the physicians of Puerto Rico recognized the claims of Dr. Koch upon the subject of the non-communicability of bovine tuberculosis to human beings. He could enumerate many instances of the communicability of bovine tuberculosis to man. The prevalent form of the disease in that island is pulmonary and intestinal. Before Gov. Allen's departure he had appropriated a sum of money for the Board of Health to use in inspecting cattle.

Dr. Lindsley could not conceive how it would be possible for tuberculosis in the lungs to be produced by the use of food, unless it first appeared as an intestinal form. He made the remarkable statement that tuberculosis, during the last ten or twenty years, has diminished in Massachusetts, Rhode Island and Connecticut; that it is diminishing in England, and, in his opinion, throughout the world.

Dr. Leonard was of the opinion that the foundations of tuberculosis were laid in infancy in the nursery, in the sleeping room and in the school-house to a far greater extent than it is possible to imagine. It is not milk and meat alone that give tuberculosis to the boy or girl or young man or woman; the absence of vitality on the part of the man and woman, the boy and girl is what renders them susceptible to the disease.

Dr. Moser deplored the stooping posture of school children with hollow chests and the standing on one foot, usually the right, thereby shortening the space between the hip and shoulder. Michigan, she said, was full of tuberculosis. Damp cellars and houses without cellars are contributory cause to the disease. In Norway, where the air is so dry and crisp that the tubercular germs could not exist, the inhabitants are extensively afflicted with tuberculosis, because the occupants of the houses permit no ventilation.

The Executive Committee recommended the adoption of the following resolution:

"Resolved that this body deplores any action in curtailing the operation of army canteens or post-exchanges and in the interest of general and military sanitation and temperance recommend their establishment as formerly existing in the United States." (Carried.)

Capt. Munson, U. S. Army, was called upon to speak of the good effects of the canteen system.

Quoting from official figures, he said that drunkenness and alcoholism had materially decreased. Delirium tremens and insanity had likewise decreased. The deposits of soldiers' savings had increased, while desertions had decreased, convictions by court martial for drunkenness and causes arising therefrom had diminished.

Dr. Ghon spoke enthusiastically on the subject and hoped the Association would pass the resolution.

(The resolution was unanimously carried, with applause.)

The following resolution was recommended by the Executive Committee, and, upon vote, carried:

RESOLVED, that notwithstanding the advances of sanitary science the mortality from tuberculosis continues to be appalling, it has been demonstrated by the application of proper measures this mortality may be diminished rapidly and to a great degree;

THEREFORE, every effort should be made by sanitarians to carry into effect all reasonable methods which have been shown by experience and research to be efficacious towards this end;

RESOLVED, that the increase of tuberculosis in cattle and swine, as shown by the investigations of recent years and by late inspection-statistics, is a serious matter from a commercial, as well as a sanitary point of view and calls for more systematic attention of those responsible for the integrity of the food-supply and for the protection of the public health;

(To be Continued.)

CANADIAN MEDICAL ASSOCIATION.

Reported by

DR. GEORGE ELLIOTT.

Our Special Correspondent.

(Continued from page 478.)

A Few Notes on the Treatment of Typhoid Fever.—Dr. J. L. Bray of Chatham discussed this subject under medicinal, dietetic and hygienic headings. The first he thought might be eliminated, except in cases where complications arise, and he thought a certain amount of medicinal treatment useful during the initiary stages. He was in the habit of employing calomel. Tympanites could be avoided to a great extent by a proper diet. In feeding he now gives very little milk, but that little always peptonized. He believes in making the patient drink two or three quarts of pure water in the twenty-four hours. Albumen water with sugar may be given from the first, after the first two weeks he gives liquid peptonoids, or some of the numerous preparations of beef, jellies, mutton broth or a soft boiled egg.

As regards the hygienic treatment, the bedding and the night clothes should be changed daily. The room should be kept thoroughly ventilated, admitting plenty of fresh air and sunshine. The patient should be sponged frequently with tepid water, and you get just as good results from tepid water as from sponging with very cold water or the cold bath, and it is not so distasteful to most patients. In hospital practice, Dr. Bray used the electric fan after using the tepid water. He has found this plan very satisfactory, especially in young and sensitive children.

Dr. Russell Thomas discussed the paper and said that he had found the ice-cup beneficial, that it did not disturb the patient and had a decided effect in reducing the temperature.

THIRD DAY—AFTERNOON SESSION.

The Address in Surgery.—This was delivered by Dr. O. M. Jones, Victoria, B. C., and it proved a very able, masterful effort. He opened his address with a reference to surgical disease in Western Canada as compared with those in the East, and stated that he had often found Western sufferers more impatient which often demanded severer methods. He illustrated this by citing a humorous incident. A lodging-house keeper, on learning that one of her lodgers was to have an operation performed on a Wednesday, wrote to the surgeon asking that it might be postponed until Friday, as her daughter was to be married on Thursday, and they didn't want the corpse home until after the wedding. The address dealt mainly with surgery of the stomach and related the deductions Dr. Jones has arrived at from his own experience of twenty-six cases. His first operation upon the stomach was in 1893,—a case of pyloric obstruction in a wily woman. Senn's plates were used. This patient died in three days, the result not being encouraging; Dr. Jones attributed the failure to the use of catgut instead of silk sutures. The introduction of Senn's plates and the Murphy button gave a great interest to intestinal surgery, as before 1899 operations on the intestines were rare. He then discussed the preparation for operation and first spoke of gastrotomy, an operation which he had performed five times for ulcer of the esophagus. In four of the cases the operation was performed with very excellent results. He then discussed the cases in which pylorotomy is indicated and said that rapidity of operation in these cases is the very important factor; prolonged operation has generally proved fatal. A suitable case should be cancer of the pylorus. The time occupied in performing the operation is not great. In one of his cases he performed posterior gastro-enterostomy. This patient still lives and it is now nearly three years since the operation. Gastro-enterostomy was next discussed. This Dr. Jones considered the most important and most interesting part of the whole subject. It is the most frequent and the most useful and the simplest of all the operations performed upon the stomach. It is performed for pyloric cancer, ulcer and stenosis and for gastric ulcer, dilatation etc. Nothing can be simpler than this operation performed with the Murphy button. Dr. Jones has used it in fourteen cases and in only one case was there any trouble. Of two of his cases, which died from shock, he examined one and found perfect union. He has found that the passage of the button has taken from fourteen days to four months; and in several cases he has not been able to obtain the button. A recital of several cases followed which proved very interesting. Dr. Jones closed his paper with a few words on perforating duodenal ulcer.

Dr. F. J. Shepherd of Montreal, proposed a vote of thanks, Dr. A. A. McDonald of Toronto, seconded this; Sir James Grant of Ottawa, supported the motion which was unanimously passed by the Association.

A Surgical Procedure for the Relief of Ovarian-Tension Pain.—Dr. Henry Howitt, Guelph, Ontario, read this paper. Is not pain frequently, if not usually, caused by tension on some nerve filament? In Dr. Howitt's opinion the answer should be in the affirmative. The operation Dr. Howitt employs is quite simple. The ovary is exposed and then a number of cross-sections are quickly made through the tense capsules in such a manner as to divide it. Then the larger Graafian follicles are opened. These are merely touched with carbolic acid. If the capsules are thickened a portion should be removed. Hemorrhage has never been troublesome. Adhesions give rise to no complications. Dr. Howitt recited the histories of two or three cases in support of the operation.

Dr. Laphorn Smith stated he had never heard of this operation before and considered that it was original with Dr. Hewitt.

(To be continued.)

New Instruments.

A NEW RECTAL FISTULA-KNIFE, TENACULUM,
AND HEMORRHOIDAL CLAMP.

By DWIGHT H. MURRAY, M. D.,

of Syracuse, N. Y.

Proctologist to Woman's and Children's Hospital and Syracuse Free
Dispensary

In the *Philadelphia Medical Journal* of June 22, I noticed a new hemorrhoidal clamp devised by Dr. G. Milton Linthicum, of Baltimore. I wish to endorse this clamp most heartily, as I found the same trouble with other clamps, including Gant's clamp, that Dr. Linthicum did; namely, the imperative use of the thumb-screw to obtain sufficient pressure to hold the tissues, thus prolonging the operation. I also find that the handles are so close together when the clamp is closed on the tissues that it is difficult to close the hand tight enough to maintain a good grip.

On account of such trouble, I devised a clamp which to all practical purposes is about the same as that of Dr. Linthicum. In my clamp I used the main principles of the lock in the parallel-jawed pliers, which are shown very well in the cuts supplied herewith. I have been using this clamp now for considerably more than a year, and am perfectly satisfied with it. The clamp was made for me by Mr. George Curry, of Syracuse. In all other clamps the difference is so manifest that it is not necessary to describe it.

FIGURE 1

Plate I, Fig. 1, shows my clamp; Fig. 2, the Kelsey clamp. Plate II Figs. 1 and 2 A represent the same clamps nearly closed, demonstrating that the fault in Fig. No. 2 A is that the clamp closes at the heel on the tissues while it allows them to slip out at the other end.

Plate II.—I desire at this time to present to the profession a new instrument which I may call a fistula-knife. It is used for the cutting out of all pockets and fistulæ about the rectum which point downward. The advantage of this over having to stop and cut at the point of the director, then split the tissues up, making two motions instead of one as with this instrument, is readily seen.

Fig. 4, in Plate III, is Gant's director for blind internal fistula which I use with my fistula-knife. I wish to commend this instrument as being the best

FIGURE 2

for this purpose of anything that I have seen. The use of the fistula-knife shortens the time of operation and has the advantage that the hand of the operator is not in his own light. In my early practice in rectal work, I had much trouble from this source until I began to devise instruments which were bent or offset in such a manner as to throw my hand entirely out of my own light. This is well accomplished in this instrument. Its knife is detachable, and different lengths of knives can be used (Plate III, Fig. 2, or different shapes, as in Plate III, Fig. 3, which has a cutting edge all around and is advantageous for dividing strictures for almost any purpose where a knife may be needed about the rectum.

FIGURE 3

Plate III.—I also present, in Plate III, Fig. 5, a new tenaculum embodying the same principles as the fistula-knife handle. Its advantages will be obvious, since they are the same as those mentioned above. I have them made with the ring in the handle like this, so that they can be easily held on one finger while we work with the other fingers. The distance of the offset can be increased or diminished according to the needs of the operator. I also have them made of different lengths from the offset to the hook. These tenacula were made for me by Mr. George Ermold, and the Kny-Scherrer Co., of New York.

Original Articles.

THE TECHNIQUE OF MAJOR AND MINOR AMPUTATIONS.*

By ROBERT H. COWAN, M. D.
of New York.Professor of Operative Surgery, New York School of Clinical Medicine.
Assistant Chief Surgeon, N. & W. R. R.

If I allow myself more latitude than the title of this paper might seem to justify, it is because there are certain points in connection with this subject, of the importance of which I have been so often forcibly reminded that I feel some consideration of them should precede the question of technique. Indeed, I felt that this paper would not only be lacking in interest, but absolutely incomplete were I to confine myself to the mere technique of amputation. My discursiveness will, I fear, very shortly convince you this apologetic explanation is not without reason. I only trust the wisdom of the decision which is responsible for that discursiveness may appeal to you with equal force. At all events, I shall, without further apology, proceed to discuss the subject of amputation, and in order to do this intelligently, it may, I think, be well to divide amputations into two classes.

(1). Amputations on account of acute injury.

(2). Amputations necessitated by some pathological condition.

It should be remembered that the very different conditions surrounding the two classes necessitate, in many respects, entirely different management. In traumatic cases, we have shock and hemorrhage with which to deal. We have had no time to give a purgative, or to have the stomach practically empty. In short, no time to prepare our patient for an operation. In the other class, the case is different. We can, at least, get our patient in the most favorable condition possible, both for the operation, and what is probably as important, for anesthesia.

Amputations on Account of Acute Injury.

Science has, to-day, taught the surgeon that, under proper care, limbs may be saved, which in the past, had been hopelessly sacrificed; and while this is true, while we save limbs, not only after injuries, for which the older surgeons would have deemed amputation unavoidable, but, even after some of a far graver nature than any they had to deal with, I doubt if there ever was an age when as much amputating was done as now. This is, of course, due to the introduction of modern machinery on our railroads and in our factories.

Railroad injuries, particularly, are characterized by features essentially their own. These features are largely due to the force and momentum of the destructive agent, and are very much more marked since the date of higher speed, and heavier rolling stock.

Crushing injuries of every degree, but almost invariably of more or less gravity, are common to-day; and, indeed, constitute by far the greater proportion of our cases. But, even in the graver class of these injuries, a surgeon's first thought should

be—can amputation be avoided? Of course if a limb is literally levered, or vessels and nerves evidently destroyed, there is but one alternative. Under no circumstances should the member be sacrificed until we have thoroughly convinced ourselves that an attempt to save it would be futile. Let us "make haste slowly" about this matter of amputating. Even if we are devoid of conscience, a one-legged or one-armed patient is not a good advertisement at best, and then, there is a medico-legal side that must not be forgotten. There are suit-inspiring attorneys, ever on the scent of personal injuries, and while nine times out of ten, the suit against the surgeon is unjust, it would be decidedly unpleasant to have our patient constitute the one justifiable case. Indeed, in this enlightened age, it is unpardonably bad surgery to deprive a fellow-being of a limb unnecessarily. The zealous gynecologist, who ruthlessly snatches a woman's ovary—he whose surgical instinct leads him to the appendix at the first symptom of pain in the right abdomen—or the enthusiast who remorselessly fixes kidneys which need no fixing—is dealing, to a great extent, with a hidden problem. The case is different with us. Though frequently problematical, we have, in most cases, the privilege of ocular inspection. At all events, our mistakes are far more patent. If the subject of a pelvic or abdominal operation live, error in diagnosis is concealed, but the maimed victim of our handiwork is a walking advertisement of the surgeon's knife. In many cases of injury, particularly those due to railroad accidents, the question of amputating, or of saving the limb, presents a most serious problem. As an illustration, I recall the case of a man to whom I was summoned, who, some ten days previously, had received a mash of the fleshy inner part of the thigh, which had been caught between the deadheads. There was no fracture of bone. The integument was unscathed, and the injury had been deemed trivial. When I saw him, gangrene or mortification had taken place. The femoral artery, and perhaps other vessels, had been destroyed. I have treated several compound dislocations, with fracture, of the ankle joint, and extensive injury to the soft tissues, saving, in each instance, not only a useful limb, but one in which the normal functions seemed almost completely restored. To these may be added injuries involving the shoulder, elbow and wrist joints, in which a like result was obtained. It was impossible for me to say, just after these injuries, whether an amputation was necessary. The extent of the injury to the soft tissues, I believed time would reveal. Hence, a temporary dressing was applied, with the result, the doubtful point in the diagnosis was cleared, and the limbs were saved. Frequently in these injuries, the skin escapes injury, betraying not even a scratch. The bone, too, remains intact, and yet, every underlying structure, save the bone, is completely disorganized. Again, I have seen mashes, where, while the skin was intact, there were multiple fractures of the bone. But as the subsequent history proved, there had been no injury, sufficient to require amputation. Time alone can determine for us the proper course in such cases. It is true, an exploratory incision may help us. Indeed, it may be necessary, not only to aid diagnosis, but if

*Read before the New York School of Clinical Medicine, June 14, 1901.

order to enable us to remove large blood clots, and secure bleeding vessels. About this, though, as a rule; I think it best to temporize. In this connection, I would like to call your attention to the wonderful resistance or resilience the integument frequently exhibits when subjected to pressure. I remember on one occasion, I was present when a man was run over by a heavily loaded box-car, the wheels passing over the upper part of the abdomen. There was but slight abrasion of the skin, though the spinal column was completely severed, and he died in a few minutes. This is but one of many instances where I have had occasion to note this wonderful property of the integument. I have seen numerous cases of mashes of every description and degree of severity, involving injury to the underlying structures, with a practically unhurt integument. This has been especially true of mashes of the arm.

But you will, perhaps, think I am "making haste slowly." This paper is supposed to deal with cases in which amputation has been decided unavoidable. Let me, then, take you where I have often been, out with a wreck-train. An accident has occurred, and several men are injured. Here is one poor fellow whose leg has been run over by the car wheels. The wheels have traversed it obliquely—almost longitudinally—from foot to knee-joint. The various structures are crushed into an almost unrecognizable mass. Incidentally, it may be well to mention here that soiled clothing, axle grease, dirt from the tracks, and, indeed, germ-bearing material of many kinds have been ground into the tissues, and it is a question whether the germs, undoubtedly present, should not be met with active germicidal agents, rather than with simple sterilized water. While this reflection may be a little premature, in a systematic treatment of one subject, it is a question of so much importance, I shall make no apology requiring amputation. The anxious expression, clouded mentality, the pallid and clammy skin, the slow (sometimes rapid) feeble compressible, or almost imperceptible pulse, tell us we have fearful shock with which to deal. The patient is restless, seemingly unable to locate the seat of pain. He begs to be placed, first in one position, then in another. He asks that the limbs be raised, then lowered. He constantly cries for water. There are others to be cared for, but a rapid examination convinces us that their injuries are not so serious. We leave them, for the present, in charge of an assistant. Our first patient needs immediate attention, and our first efforts are directed to relieving shock and restraining hemorrhage, and we defer amputation until there is decided evidence of reaction. Now let us look at the others. The next man has a compound comminuted fracture just above the ankle. The soft tissues are badly mangled; little or no shock. The third man has a terribly swollen arm. The bone is evidently comminuted. There is absolutely no pulse, but, strange to say, the integument is intact. The diagnosis in this case is not absolutely clear. The chances are an amputation will be necessary, but we will give the man the benefit of the doubt. Time may indicate more clearly our

proper course. While we wait, we amputate the leg of the second man—taking care we cut well above all tissue of doubtful vitality. This being done, let us again examine the mashed arm. Complete destruction of muscular tissue, with rupture of the vessels, seems almost certain. But perhaps we err in our diagnosis. There may yet be sufficient blood supply to warrant an attempt to save the limb, while that which has escaped into the tissues, becoming clotted, and thereby mechanically interfering with vessels yet intact, may account for the absence of circulation. We make an exploratory incision, and find nothing but pulped tissue and blood clot. Our only recourse is to amputate. Has our treatment of these three cases been correct? I think so. In the first case, shock was so profound that I am satisfied the additional shock of anesthesia and operation would have killed the patient. Of the other two injuries, that of the man with the mashed arm was treated last because the diagnosis was not quite clear. In the second case, a very slight operation, it could be quickly done, and was obviously required. But, in order to make my position with regard to these injuries more clear, it will be well, at this juncture, to discuss at some length the principles governing amputations done on account of acute trauma.

In every case of severe injury requiring amputation, there are three questions which usually confront the surgeon. They are as follows: The treatment of shock. When to amputate. Where to amputate.

The Treatment of Shock.—In the discussion, following a paper on Shock, which I read before the Fifth Annual Meeting of the New York State Association of Railway Surgeons, Dr. George Chaffee, of Brooklyn, said: "Just what shock is, we do not know." Dr. Estis, in his paper, mentions the psychical element and hemorrhage. We may get profound shock without the loss of a drop of blood, or we may get it from hemorrhage alone, and notwithstanding this idea is very much opposed by some, I am sure, if not the sole factor in its production, hemorrhage, in some cases, at least, plays a very considerable part in maintaining and increasing shock. I may be permitted to quote from my own paper, to which I have referred: "In shock, a systemic disturbance, characterized by general vascular relaxation, stagnation is naturally marked in the abdominal circulation. The feebly supported vessels, readily yielding, become the receptacle for the bulk of the circulating fluid, in consequence of which we have a condition of anemia from hemorrhage into the veins, as decided as though the blood were withdrawn from the body. Should the injury be complicated by external bleeding, this condition is simply aggravated." Shock may be of psychic origin, solely, as in cases of sudden fright. Whatever be its origin, however, *shock is a condition of anemia*. The anemia may be due to external hemorrhage, or to slowness of the venous return, and consequent insufficient supply to the heart. That organ is, in turn, unable to supply the arteries. The anemia is, probably, an effect—the pathological condition, if I may so call it; not an etiological factor in the production of shock. It is not the etiol-

ogy, however, which so much concerns us here. The condition we find is one of acute anemia, and of nervous exhaustion, and our treatment should consist in an effort to stimulate and tone up the depressed nerve centers and restore the circulation, and thereby relieve the anemia of heart and brain. Nitrate of strychnia should be used hypodermically, and with the exception of nitro-glycerine and nitrite of amyl, which on account of the rapidity of their action are valuable, I know of no other drug which proves useful in shock. Whiskey is, for the most part, worse than useless. Its secondary effect is to depress the vital forces, and to lower the temperature. Nor must we forget the inability of the stomach to digest, and the danger of over-loading that organ, producing nausea, and thereby increasing the depression. The intravenous, or intracellular injection of a hot saline solution is one of the most valuable means we possess for combating shock. Possibly the *most valuable*. An important point, and one of which we should not lose sight, is the importance of keeping the patient warm. The hot operating table, now in common use in all thoroughly equipped railway hospitals, is a most excellent thing. An old-fashioned custom was to pack hot water bottles about the patient's extremities. I never quite understood the *rationale* of that treatment. I fancy a hot water bag over the heart would be of more service.

When to Amputate.—In deciding this question, the surgeon must, to a great extent, be governed by the degree of shock, both systemic and local, and here let me say, in my experience, an operation done under profound shock almost invariably results fatally. Where a limb is well-nigh completely severed, and the splintered bone, irritating the torn tissues, may increase and prolong shock; it is well with a sharp knife or scissors to sever the remaining structures, secure bleeding vessels, and apply temporary antiseptic dressing, but our main efforts should be directed to relieving shock.

I have spoken of *local shock*, by which I mean a devitalization or lowering of resistance of tissues to a point more or less distant above and below the apparent site of the injury. Every surgeon of much experience in railway trauma recognizes this condition, and is well aware that the amputation, in all probability, will have to be done much higher than one uninformed would suspect. This condition is readily recognized in the pallid integument, and in the bluish deadened appearance of the muscles. The temperature of both structures is decidedly lower than that of immediately adjacent tissues. In certain cases, these apparently dead structures will, in a few hours, give evidence of returning vitality; the skin will show the blush of health, and the muscles regain their normal color and temperature. In others there is no change, but the line between the dead and healthy tissues is more clearly defined. I do not refer, of course, to the line of demarcation occurring in what we call mortification. It is too early for that. In an experience of nearly twenty years of railway surgery, I have not yet learned to decide, with certainty, immediately after an injury—at least in many cases—exactly what amount of tissue is permanently dead, or to what extent a mere lower-

ing of resistance, or temporary local shock may be followed by healthy reaction. Let me repeat: let us go slowly. A limb may be sacrificed if an immediate amputation be made, whereas, a reasonable delay would have convinced the surgeon that the tissues possessed sufficient vitality and reparative power to warrant, at least, an attempt to save the member. On the other hand, should he do an immediate amputation, he will most likely find to his chagrin that he has cut too low—the entire flap badly sloughing. I presume I have made sufficiently clear my position with regard to immediate amputation. If not, let me say, in a very large proportion of injuries to a limb, I am *most emphatically opposed to immediate amputation*—always in profound systemic shock, and not infrequently in the absence of systemic shock, in certain cases where we are in doubt as to the extent of injury to contiguous tissues. I believe it is good surgery, and a duty we owe to our patient, to give the tissues a little time. I am well aware a number of most excellent surgeons, men, too, of vast experience, will take issue with me here. They insist on immediate amputation, even under profound shock. They claim the anesthetic acts as a stimulant, and the sooner the limb is off, and the wound nicely dressed, the better for the patient. As far as any beneficial stimulant effect is to be derived from the anesthetic, I am sure it must be very transient, and surely followed by depression, and most frequently by a nausea which must add to the depression. That the lacerated muscles, torn nerves, splintered bone, and oozing vessels, all exposed to the air, may keep up shock, certainly seems reasonable, and I believe it is good practice to cut off ragged tissue, secure bleeding vessels, and indeed, where this can be done, completely sever the limb, which under grave shock is usually painless, and only means the division of a small amount of more or less deadened tissue. The wound can then be cleansed, and a temporary dressing applied.

Unquestionably hemorrhage adds to shock, and it is far better to secure the individual vessel or vessels with ligature or hemostatic forceps (or in the case of the smaller ones, torsion) than to apply an Esmarch, which is always attended with danger if kept *in situ* too long, as well as causing much discomfort to the patient.

Where to Amputate.—This is a question of most serious import to the patient, and on our decision will depend the future usefulness of the mutilated members. We are about to perform an operation which has been called "the op-probrium of surgery." We are about to sacrifice a limb, to complete, though, in a more skillful manner, the unfinished work of the injuring agent. We are forced to this butchery, because, in the present state of our knowledge, it is the best we can do. In thigh amputations it should be remembered the further we keep away from the trunk, the greater the patient's chance of recovery. It may be laid down as a general rule that every inch should be saved that is possible. This rule, however, is by no means without its exceptions. Naturally the great *désideratum* is to provide a stump that will afford the greatest possible use. For instance, in an

injury about the knee, it may be better surgery to go just above the joint, thereby enabling the patient to wear an artificial limb with more comfort than if it were simply disarticulated at the knee joint. Again, in an amputation between the ankle and the knee, it may be better to sacrifice an inch or two, in order to avoid a split in the bone, or to secure a good flap; or, again, to get rid of doubtful tissue; the difference in the site of amputation making, practically, no difference in the wearing of a prosthetic appliance. In dealing with injuries to the hand or fingers, we should use the utmost conservatism. Every finger, or part of a finger, that can, should be saved. A short time since I had to amputate a man's right arm, and the left hand was so badly injured I was only able to save the little finger and one phalanx of the thumb. You can readily imagine what a boon even that remnant of hand is to him. Where but one finger is injured, and that one certain to be ankylosed, I think amputation the wiser plan. For he can better afford to lose one finger than to have a stiff and practically useless digit in his way. I have frequently been applied to, by workmen, who have found such a member, whether put up straight or partially flexed, a most serious annoyance.

Amputations Undertaken on Account of Some Pathological Conditions.

Some reference to the pathology in the various diseased conditions for the relief of which amputation is often necessary, seem unavoidable in any discussion of the subject, but it must, in this paper be necessarily brief.

I shall take up first, Amputations for Traumatic Gangrene.

While for some reasons these might be more appropriately classified with amputations on account of trauma, I have preferred, inasmuch as the amputation is done for a *pathological* condition which has supervened, and not on account of the original injury, to consider these operations with those done for other pathological conditions. Gangrene may result from almost every variety of injury; the essential factor in its production being interference with the nutrition of the part, and this may be due either to interference with the arterial supply and venous return, or to a stasis in the capillaries, complete or partial section of a large vessel (either artery or vein) or, indeed, any wound of a vessel may cause this condition, not only because the vessel is no longer capable of carrying blood, but the blood, poured out, and clotted in the tissues, forms a mechanical obstruction to both the arterial supply and the venous return. In extensive crushing injuries so common in railway cases, while no large vessel may be severed, gangrene not infrequently occurs as the result of a hyperemic and stagnated condition of the capillary vessels, due to the intensity of the inflammation which is prone to set in.

A wound of very limited extent, becoming infected with micro-organisms, may complicate this condition, producing disastrous results, the gangrene spreading with great rapidity. Dr. Thomas H. Manley makes, what seems to me, a very proper distinction between gangrene and mortification. "Mortification, naturally, means the death of the

part. Gangrene, a pathological condition, not necessarily terminating in mortification." Manley enumerates "the pathological conditions most obvious in the tissues, after great violence," as follows: (1) "Suspended animation, or asphyxia. (2) Inflammatory changes. (3) Gangrene. (4) Mortification." He also divides gangrene into "acute and sub-acute." In the acute form, necrosis of the tissues takes place with such frightful rapidity that there is, usually, little time to lose in an attempt to save the limb. Amputation should be done well up the limb, indeed, it is, I think, seldom wise to wait for a line of demarcation, in any case of gangrene of sufficient severity to render amputating necessary. It is not to be inferred, however, that I would advise amputation in every case of extensive gangrene occurring in a limb. I have frequently seen large masses of tissue become gangrenous, necrotic, and finally separate from the underlying healthy tissue. Gangrene is, of course, not necessarily the result of trauma. Emboli or thrombi may occlude the arterioles, or pathological changes producing thickening of the intima may cause a stagnation in and final occlusion of smaller arteries, as occurs in senile gangrene. Then, we have a very intractable form of gangrene, which occurs with such frequency in the subjects of diabetes and albuminuria that we speak of diabetic gangrene or albuminuric gangrene. Exposure to excessive cold is another cause of gangrene. The cold contracts the arteries. Thrombi are formed, and, finally, the smaller vessels become obstructed. In amputations done for diabetic gangrene, or any form of gangrene resulting from a depraved condition of the general health, our prognosis should be made with great caution. The results in these cases have not been gratifying, and, in fact, it may be laid down as a general rule, that whenever amputation has been decided upon, whether for traumatic or idiopathic gangrene, "if 'twere done, 'twere well 'twere done quickly," and we should be sure we get sufficiently beyond the dead or diseased tissue to minimize the danger of sloughing of the flaps, a very common occurrence, and one necessitating a second amputation.

In osteosarcoma, occurring in a limb, we are frequently called upon to operate. An early recognition of the disease, and a timely operation may give a gratifying result in some cases, but I do not think successes here have been strikingly brilliant.

Osteomyelitis, so frequently of tubercular origin, so insidious in its approach, and so frequently unrecognized until too late to save the limb, is another condition for which amputation is sometimes necessary, and if done in time, has, in my experience, given good results.

In all these conditions the patient, usually being in a very low state of health, the rapidity with which we operate becomes a matter of first moment. This is especially true in operations for diabetic, and in fact, every variety of gangrene. The lowered vitality, too, of the tissues, renders the flaps peculiarly liable to slough; hence, with a view to saving as much tissue as possible, and to getting through the operation quickly, the transfixion operation by which we secure a musculo-cutaneous flap, is to be preferred. Before performing any operation our in-

struments, towels and surgical dressings must be carefully sterilized. We are then ready to anesthetize the patient, and I want to say a few words here; first about the instruments, then the anesthetic. In emergency surgery our armamentarium should be as simple as may be consistent with the requirements of accident cases. I am speaking now, more especially, with reference to cases treated remote from a hospital; in a private house, possibly a hut or cabin off in the country. Our instruments, dressings, etc., must be carried in a hand satchel, as we do not wish to burden ourselves, or take up valuable space with aught that is unnecessary. Senn says: "Very few instruments are required for even complicated operations, provided proper selection is made, and the surgeon knows what he should about operative technique." Only two scalpels of moderate size are included in the list which he gives for an emergency case. "The old-fashioned, sword-like amputating knife" is rarely seen now, "as all surgeons have abandoned the transfixion method, and make all amputations with a medium-sized scalpel." At all events, it is undoubtedly true that too great an array of instruments, in emergency work, may prove as embarrassing as too few. It may sometimes happen we are called in to do operations with a very scant supply of instruments, and it is in just such emergencies our resources are most severely tried. We should endeavor to be equal to the occasion. Some years ago, one dark rainy night, I was called to see a man whose leg, including the knee and lower part of the thigh, had been frantically mangled. I had nothing with me but a satchel containing gauze, cotton and bandages. I had no instruments save a number of hemostatic forceps, which happened to be in the satchel. I had been to dress a case of amputation, and my instruments were at home—forty miles away. The place was in the mountains, remote from any town. No surgeon could be obtained. The country doctor whom I found with him had no instruments. The man was suffering greatly, reaction was good, and there was considerable hemorrhage. The only assistants to be had were three or four section men, and the place for operation was a cabin, containing one small room and a smaller kitchen. One lamp and two or three lanterns afforded light. I had them get ready an ample supply of hot water. I then borrowed a good-sized pocketknife from one of the men, a large needle and some stout linen thread from the woman of the house, and a new carpenter's saw from a neighboring country store. Having sterilized my instruments as best I could I did a thigh amputation, which in its mechanical execution and after-result was as successful as though done with every facility possible. I have mentioned this case because I think it instructive, showing that, if forced to it, we can do good work with very limited resources. I have had other experiences not unlike this. We now come to the question of anesthesia, and about pulmonary anesthesia I shall say but little. I have already expressed my conviction that an anesthetic should never be administered to a patient under profound shock, and to this I will only add that its administration should be entrusted to an experienced and watchful person whose entire

attention should be devoted to the anesthetic. Now I want to call your attention to the use of cocaine as a local analgesic, not merely in minor amputations, for all surgeons use it in such cases to-day, but in the more serious operations. I did my first major amputation with cocaine, in 1890, and since that time have done twenty-five major amputations, including three of the thigh, using cocaine injected hypodermically: first, just beneath the integument, and then more deeply into the tissues. I use the Esmarch, as advised by Corning, but I invariably apply it before injecting the cocaine, which is, I fancy, far safer than to inject before its application. My experience with this drug has been satisfactory in every instance, both as regards its analgetic effect and the after condition of the patient. Nor have I been able to notice any toxic effect. I have thought cocaine particularly applicable in cases where, though shock was great, an immediate amputation was for any reason deemed advisable. In such cases it has proved, in my hands, most satisfactory. Time will not permit me, here, to say more about cocaine, and as I have already published reports of my cases, I will go on to the actual technique of amputations.

The Technique of Amputations.

The patient having been anesthetized we proceed to prepare the field for operation. The part is first cleanly shaved, then thoroughly scrubbed with a reliable antiseptic soap, then washed well in sterilized water, or, perhaps, in some cases, with a bichloride solution. Then with ether, and lastly with alcohol. An Esmarch bandage is next applied, and we are ready to operate. In any case of traumatism requiring amputation between the joints, that is, in the continuity of the shaft of the bone, I should unhesitatingly advise the circular operation, in which an incision is first made through the integument and subcutaneous areolar tissue, which is dissected and turned back like a cuff. Then, while the cuff is held firmly back by an assistant, with a sharp scalpel we encircle the limb, cutting through the muscles to the periosteum. I do not think it well to waste much time in the effort to dissect back a periosteal flap. Doubtless, when it can be done, there is some advantage to be gained in covering the end of the bone. I think, though, as good results are obtained where this is not done. Having sawn through the bone, with a strong cutting forceps, which should be very sharp, we *slightly* bevel the edges of the bone, and our amputation, as far as regards the severance of the limb, is done. The vessels are then caught in the grasp of a hemostat; in order to find them it is sometimes necessary to loosen our Esmarch a little. The larger vessels should now be tied with medium-sized catgut (very strong). Torsion will suffice for the smaller and is by some surgeons the only means employed with any vessel. Silk, in my estimation, should never be used; for a ligature left hanging from a vessel, so that it may be removed, is liable at any time to be subjected to undue strain, and tearing from the vessel may cause secondary hemorrhage. Not only this, but as it sometimes remains a long time, it may, acting as a foreign body, produce ulceration with danger of hemorrhage. Nor is this all. The silk ligature, an absorbent material, may prove a

ready means of carrying in septic material, which may interfere with the normal physiological process which seals the vessel.

In tying the vessels we can not be too careful to exclude any portion of nerve or nerve fibre. I have known several instances where much acute suffering was caused the patient from the inclusion of a nerve in the ligature. The nerves should now be found, and carefully and squarely clipped, being gently drawn down for that purpose, so that when cut they will retract well within the muscular tissue. The inclusion of a nerve in the cicatrix means a painful stump, and may even prove so painful as to require another operation.

The operation I have described is that for circular amputation. The older, transfixion operation (in operations after injury) possesses no advantage that I can see over the circular method, while I do see serious objections to it. Vessels and nerves are cut through obliquely, and are often difficult to find. Then we have a large musculo-cutaneous flap which is in no way desirable. We have abundant proof that the muscular tissue in such flaps is always absorbed, and consequently an operation done with a view to obtaining a cushion of muscle for the end of the bone is unscientific, and possibly productive of harm. Truax says: "In performing an amputation that will best serve the interests of the patient all superfluous and useless bone and tissue should be removed that they may be replaced by artificial material that will be of service and value." A non-adherent flap consisting merely of integument with underlying connective and cellular tissue, is the ideal flap when an operation is done on account of acute trauma. In arm amputations the transfixion method gives a very neat looking stump immediately after the operation, but I think that is about all that can be said in its favor. It is, however, less objectionable than when done in the thigh. In operations rendered necessary on account of some pathological conditions, particularly in diabetic gangrene, and in any depraved constitutional conditions, we are very apt to have sloughing of the flap—as has been mentioned above—owing to the low state of vitality of all the tissues. For this reason, and also because of the expedition with which this operation can be done—which is a very important matter—I believe the transfixion operation the most satisfactory. While, if the patient survives, the muscular tissue will undergo, undoubtedly, absorption, it at least temporarily serves as a nidus for the ramification of vessels that may nourish the cutaneous flap. It often happens that in injuries in which there is much contusion or laceration of the integument we are forced to make our flap where we can obtain healthy skin, and this may necessitate a long flap, anteriorly posteriorly, or from one side of the limb. Hence, no fixed rule can be laid down as to the selection of the flap in such cases. Some surgeons lay much stress on the shape of the integumentary flap. I do not believe, however, it matters much if we secure sufficient healthy integument to cover the bone and raw surface. The important point is to see that the edges of the flaps are nicely approximated, so as to avoid the production of granulation or scar tissue, which

does not bear pressure well. It must be remembered, however, that in modern prosthetic appliances the pressure is not received by the end of the stump, but is distributed over the surface of the limb in its entire circumference.

Presuming, now, we have done a circular amputation, vessels have been tied or subjected to torsion, and nerves severed well up in the tissues, we are ready to close the wound, provided there be *no oozing*.

Should there be oozing, pads of gauze soaked in very hot water should be successively applied to the raw surface. It is sometimes well, with a large pad, to produce considerable compression. The pad must be retained in apposition with the raw surface for some minutes. What we want is a *dry* wound, and we should not close it until this condition is secured. Having arrested all oozing, in thigh or arm amputations, or wherever there is much muscular tissue, several silk worm gut sutures should be carried through the skin, deeply into the muscular tissue, and out through the skin on the other side. These sutures should be drawn tightly enough to obliterate the dead space which would otherwise exist between the severed ends of the muscle and the integumentary flap. They also serve to prevent an undue degree of tension on the superficial sutures. They should be slotted when in position.

Finally the integumentary flaps are closed, either by running or interrupted sutures. I prefer the interrupted sutures, for, if from any cause one suture gives way it does not mean the gaping of the entire wound as might occur with the other. The sutures should be of catgut or some absorbent material and may be embedded or not, as the operator may think best.

I have no use, in these cases, for silk sutures, and should only use them when I have no hope of primary union. I have not referred to drainage, because, if we have a clean wound, and get that wound thoroughly dry, before closure, and then apply a proper protective dressing, I think the drain is only in the way, and can but irritate, and possibly prove a source of infection. At all events it is certainly unnecessary. After having closed our wound under the strictest asepsis, *dry* sterilized gauze should be applied, so as to entirely cover the part. This should be held in place by gauze bandages, then the whole should be enveloped in sterilized cotton, and this in turn secured by a nicely fitting cotton bandage. After an amputation of a lower limb, especially the thigh, a well-padded splint should be applied posteriorly, and the limb elevated. It is hardly within the scope of this paper to give a detailed description of the various amputations devised by different surgeons, and yet no paper on amputation would be complete without some reference to Wyeth's bloodless method of amputation at the hip joint, where hemorrhage is controlled by means of transfixion pins, and rubber tubing, which is equally applicable in amputations at the shoulder. By this method Wyeth recently reported the death rate in amputations at the hip joint has been reduced to less than ten per cent. in cases where the procedure is necessary from causes other than acute trauma."

A number of ingenious operations have been devised, prominently among which may be mentioned Symes, Pirigoff, and Chopart. I shall not attempt a description of these operations, nor of the different methods employed in those of the shoulder and hip joint. With these you are as familiar as I, and in cases of trauma, and not infrequently in diseased conditions, no orthodox plan can be followed, and the surgeon's ingenuity must decide where to cut, and how to fashion his flaps. I can only say in conclusion, I should never, unnecessarily cut away any portion of a limb which I believed it possible to save, provided always the part saved will prove useful. In the foot, if the toe must be sacrificed, I would simply disarticulate at the metatarso-phalangeal joint. Or were there reasons requiring me to go higher I would do a medio-tarsal amputation. In the hand, as I have said before, I would save every finger, or part of a finger possible.

LACERATION OF THE CERVIX UTERI*.

By HENRY D. BEYEA, M. D.,

of Philadelphia.

Associate Surgeon, Gynecean Hospital, Assistant Gynecologist, University Hospital; Instructor in Gynecology, University of Pennsylvania.

Gentlemen: In presenting this paper on laceration of the cervix uteri before you, I do not wish to enter upon an exhaustive discussion of the whole subject of laceration of the cervix, but to consider practical points in the pathology, symptomatology and treatment of this disease, which after a large experience, I have found, are not generally recognized and fully appreciated by the medical profession. Sufficient importance is not attached to lacerations of the cervix uteri as a cause of suffering in women, nor is sufficient attention paid to certain details of the operative technique, the understanding and practice of which are so very necessary for the relief of such suffering.

A large number, I think, perhaps the majority, of the women upon whom I operate for laceration of the cervix tell me that they had been previously advised by one or more physicians that there was no uterine disease which required operative treatment. Or, they very frequently tell me that they have been told that there was an ulcer of the neck of the womb, which could be cured by local applications and vaginal douches. For these raw looking surfaces are still generally called ulcers, notwithstanding the fact that Emmet has been teaching the true cause of this so-called ulceration since 1869, and that Ruge and Veit and many others have shown their true pathology; that the apparently raw surface is covered with cylindrical ciliated epithelial cells, and is in no sense an ulceration. Emmet tells us that at least one half of the ailments among those women who have born children are to be attributed to laceration of the cervix uteri. It is my belief that most and often all of the symptoms complained of by this proportion of women are caused by such an injury and its secondary pathological lesions.

What are the most important of these ailments?

The usual form of laceration which we see is a bilateral tear which results in a separation or a rol-

ling out or an eversion of the anterior and posterior lips of the cervix. The cervical mucosa is no longer contained within a closed canal where it is protected. It is exposed to friction and pressure against the posterior vaginal wall at all times, but most when the woman is on her feet and the heavy uterus sinks toward the floor of the pelvis. Being a true mucous membrane containing racemose glands, the Nabothian glands, the lining of the cervical canal does not become hardened or toughened by such exposure. After the elapse of years it may become converted into cicatricial tissue, but until that time it is a constantly irritated surface, just as a prolapsed mucous membrane of the rectum or an ectropion of the conjunctiva. The surface epithelium undergoes hypertrophy and hyperplasia, the proliferation of the cell elements resulting in an extension of the mucosa beyond the normal limit. The mucosa grows over the lacerated surface to the right and left on each lip and often onto the portio vaginalis, presenting the appearance erroneously called ulceration. The rolling out of the lips of the cervix obstructs the circulation at the base of the lips in the neighborhood of the internal os, continuous passive hyperemia or chronic congestion results in swelling and hypertrophy of the glandular and stroma tissue and the cystic changes we are familiar with. The large number of racemose glands of the cervix become inflamed; they proliferate, the orifice of the ducts becomes occluded, so that the whole hypertrophied vaginal cervix in extreme cases becomes a mass of cysts, varying in size from a mustard seed to a pea. In the stroma tissue immediately surrounding these glands or irregularly distributed is more or less small round cell infiltration and infiltration of polymorphous leukocytes. The stroma cells show hypertrophy and hyperplasia. The blood vessels the usual hyaline degeneration. In the more chronic and very chronic cases localized or diffuse areas of cicatricial fibrous connective tissue is seen. The condition from beginning to end is one of eversion or ectropion of the cervical mucosa with hyperplasia of all structures, secondary inflammatory changes. The extent of inflammatory change being only slight, or advanced to extensive cicatrization. It is never in the usual case of laceration of the cervix an ulceration, and only very rarely is it an erosion, for by an erosion we mean a loss of substance.

So much for the cervix, now for the uterus. Lacerations of the cervix take place in a uterus enlarged by pregnancy, and for this reason lesions occur which would not occur if a simple bilateral incision were made in the cervix of a non-pregnant woman. Subinvolution follows, and the lesions are those incident to subinvolution, glandular endometritis, retrodisplacement, general pelvic congestion and very frequently secondary chronic catarrhal salpingitis and chronic oophoritis.

Finally, I wish to particularly call attention to the very significant result of continuous irritation from the split of the cervix, from the inflammatory change I have described, namely the involvement of the pelvic lymphatics, the presence of a persistent metro and perilymphangitis and lymphadenitis. A condition which it is customary for me to describe as a

* Read before the Cumberland County District Medical Society, New Jersey, May 1900.

retro-sacral cellulitis; the lymphatics and tissues of the retro sacral ligaments being inflamed and thickened. None of us will underrate the suffering, the disability accompanying this condition when we recall the lameness accompanying an inguinal lymphadenitis, due to such a small cause as a minute sore upon the penis or an irritating corn. Similar lameness is caused by the pelvic pain resulting from lymphadenitis excited by a fissure or an irritating surface upon the neck of the uterus.

Admitting all of these lesions as results of the laceration, what symptoms would we expect to find produced by them?

Backache, sideache, headache, leucorrhea, menorrhagia, sometimes dysmenorrhea, neuralgia in any part of the body and reflex nervous symptoms caused by the pelvic focus of irritation, constantly nagging and exhausting nervous energy.

We recognize similar reflex nervous disturbances and acknowledge the cause in the case of such an irritating lesion as a fissure of the anus, while some of us are slow to admit that much disturbances may be caused by an irritating lesion of greater physical dimensions in the neck of the uterus. All of the symptoms described, in various degrees and combinations, accompanying lacerations of the cervix uteri of even small magnitude, and these symptoms are due primarily to the laceration. The proof of this is within the reach of all of us, for the proper repair of the injury in suitable selected cases will relieve the woman of all suffering. This brings me to the consideration of the cases suitable for operative treatment and the method of operating. There are three kinds of laceration to which I shall call your attention. These are the bilateral, the incomplete, and the combined bilateral and incomplete.

The bilateral laceration of the cervix uteri can only be properly recognized by the examining finger or by inspection after the vagina has been opened with the Simms speculum. The bivalve speculum masks the lesions. If the examiner keeps before his mind the conical or dome shape of the normal cervix, he will usually recognize a laceration by digital examination. The examining finger comes in contact with the broad surface of the cervix, the center of which is occupied by what appears to be the external os, but really is a part of the cervical canal some distance above the external os. The finger then glides posteriorly over the broad cervix, passes around a corner, either rounded or sharp, and enters the posterior vaginal vault. If passed anteriorly it enters similarly the anterior vaginal vault. The presence of the corner or edge is indicative of a bilateral laceration. It is never felt as the finger is passed over the normal conical cervix. In some cases of bilateral laceration it exists in a very marked degree and it can be rolled in by the finger introduced in the posterior vaginal vault. In other cases it becomes rounded by swelling of the cervix, and the condition of two gaping and rolled out lips is not so strongly marked. In these cases, however, the cervix feels flat and broad, and is in no sense conical or dome-like, as in the normal condition.

The condition is still more readily recognized if the woman is placed in the Simms position or the

knee-chest position, and the cervix is exposed by retracting the perineum with a Simms speculum. If, then, the anterior and posterior lips are caught with tenacula and drawn toward each other, the apparent ulceration or erosion, truly the eversion of the cervical mucosa, disappears and the normal shape of the cervix is produced. In any case of doubt this test will make plain the character of the lesion.

You are probably familiar with the nature of what has been called incomplete laceration of the cervix, but I direct your attention to it because its existence is so often overlooked. In incomplete laceration of the structures of the cervix are split unilaterally, or bilaterally to, but not through the mucous membrane of the vaginal aspect of the cervix. The two lips are then held together and gaping is prevented simply by this mucous membrane of the vaginal aspect alone. The split may extend from the external os to the internal os, converting the cervical canal from a cylindrical or slightly spindle shaped structure into a cavity as broad as the transverse diameter of a hypertrophied cervix. The same inflammatory changes and proliferation of tissue takes place as in the bilateral tear. This condition can readily be recognized by passing a sound into the cervix, when it will be found that it comes directly in contact with the mucous membrane of the vaginal aspect of the cervix. This form of laceration is not very common. I mention it because it is so often overlooked. The combined condition, however, of a complete bilateral laceration or split of the lower part of the cervix with an incomplete laceration of the upper part is in my experience not unusual, and the appreciation of its presence is of great importance. In this condition the eversion or rolling out of the lips of the cervix is not very marked, because they are held together above by the intact mucous membrane of the vaginal aspect. There are present the inflammatory changes, a very profuse leucorrhea and other symptoms of laceration more marked than one would expect from the visible lesion. The detection of the incomplete part of the laceration it readily made with the sound. In operating for slight bilateral tears of the cervix one will often discover this condition of incomplete laceration in the upper portion of the canal if the excision of tissue is carried well up toward the internal os, by splitting the cervix beyond the point of apparent bilateral laceration. It will then be found that almost as high as the internal os the anterior and posterior lips of the cervix have been only held together by the mucous membrane of the vaginal aspect of the cervix. The recognition of this condition and its operative repair are most essential to the success of the operative treatment.

Success in treating lacerations of the cervix uteri depends upon the following four factors:

1. Proper selection of cases.
2. Preparation for operation.
3. Attention to certain essential operative details.
4. Selection of the proper operation in the individual case.

The selection of cases is most important. In many cases of laceration of the cervix uteri the operation

of trachelorrhaphy is contraindicated. It not only will not cure the woman, but it may kill her. Failure to recognize the contraindications has resulted in a great deal of harm, and has done much to bring discredit on the operative treatment of laceration. The chief contraindication to operation is the presence of pelvic inflammatory trouble outside of the uterus, the presence of disease of the tubes and ovaries. Emmet recognized this contra-indication before the days of our modern pathology of pelvic diseases, when he advised the preparatory treatment with hot douches and vaginal applications, until all symptoms of "pelvic cellulitis" indicated by lateral tenderness and fullness had disappeared. Marked disease of the Fallopian tubes may in general be considered a contra-indication to the operation of trachelorrhaphy; or at least a contra-indication to trachelorrhaphy alone, uncombined with salpingo-oophorectomy.

The presence of pyosalpinx exposes the woman to a very obvious danger, the danger of an acute attack of pelvic inflammation if the uterus is subjected to the traumatism and manipulation incident to trachelorrhaphy. Most of the deaths after the operation of trachelorrhaphy are due to this cause, and we should not only never have a death after the operation, but the convalescence should be easy and painless. If a woman suffers with local or general peritonitis after trachelorrhaphy, the condition is due to one of two causes; failure to recognize pre-existing inflammatory disease of the Fallopian tubes, or septic infection introduced at the time of operation. The first, I think, is the usual cause.

I have not unfrequently heard of the death of the patient in this way, a tubal abscess rupturing and the patient dying of general peritonitis. I have several times operated for pyosalpinx upon women who had but a short time before been subjected to the operation of trachelorrhaphy. Tubal abscess is too often overlooked, in these cases.

It is not sufficient warrant for the operation of trachelorrhaphy merely to introduce the finger into the vagina and to recognize a laceration of the cervix, or to introduce a speculum and see the gaping os. A most careful bimanual examination is necessary to determine the condition of the tubes and ovaries, and this examination should be made a second time as a final precaution, when the woman is under ether, immediately before proceeding to the operation of trachelorrhaphy.

Another important factor to remember is that when a woman has a lacerated cervix there usually co-exist other lesions, repair of which is also necessary before perfect health can be restored. Failure to recognize these other conditions results in disappointment to physician and patient. Trachelorrhaphy alone will not cure the woman if she suffers also with endometritis, retrodisplacement, and loss of muscular support to the pelvic floor. Curetting of the uterus is usually a valuable addition to the operation of trachelorrhaphy, and perineorrhaphy is in most cases also necessary.

You are, of course, familiar with the operation of trachelorrhaphy for repair of laceration of the cervix, which was invented by Emmet. But there are

several very important points essential to the success of this operation which, I find, are very often neglected. First, the previous preparation, or preparatory treatment of the cervix for operation.

Women are often sent to the Gynecean Hospital suffering with old laceration of the cervix uteri, with the request from the physician that they be operated upon immediately. The tissues of the cervix are hypertrophied, hyperemic and chronically inflamed, often full of Nabothian cysts, sclerotic, presenting a wide surface eversion. Such a cervix is in no condition for operation. Most women with old laceration of the cervix uteri require a certain amount of local treatment before the operation can be successfully performed. Such treatment, depending upon its influence, may require ten days or a month. It consists in the free puncture every four or five days of the whole cervix to evacuate the cysts and to relieve the congestion. It is a process of depletion of the stroma tissue and in opening the gland cysts allows the glandular structure to contract toward normal size and new gland cells to develop. To still further aid this same process the whole vaginal vault, the vaginal cervix and exposed everted mucosa should be painted with Churchill's tincture of iodine, and a glycerine or glycerine and ichthyol tampon introduced in contact with the same surfaces. The tampon should be removed at the end of twelve hours. With the same object large (1½ to 2 gallons) hot water douches are administered twice daily, one being given before retiring. The details of giving such a douche I need not mention. The change which takes place in the cervical tissues, and in the feeling of the woman after from one to four weeks of this treatment is wonderful. The enlarged, the hypertrophied and hyperplastic cervix diminishes in size, the cysts disappear, the inflammatory tissue is greatly absorbed, leaving no cicatricial change, the cervix is softened, the area of proliferated mucosa seems to shrink. This last change, however, is only apparent, and is due to the proliferation of the cylindrical epithelium, which, instead of being a single layer, is now composed of two or more layers and becomes cuboidal or even squamous. With the improvement in the local condition, the woman's suffering diminishes.

The backache, sideache, headache, leucorrhea improve; and we often find that women after such local treatment refuse operation, because they feel perfectly well. Operation is, of course, however, necessary, for the old condition will surely return as soon as the local treatment is stopped. Such local treatment not only makes the operation more certain of curing the woman, but it renders the operation very much easier of performance. There is less bleeding; the tissue is less friable; the amount of tissue to be excised is more accurately determined; it is removed smoothly and regularly; and the sutures can be passed more easily and with more precision. In the case where these changes have taken place following such a treatment, in those of recent tear or where extensive pathological change has never been present, represent the selected cases for the operation of trachelorrhaphy.

If, after a few weeks of rest and such local treat-

ment, there is not a decided improvement in the condition of the cervix, then, in my opinion, it is very doubtful whether the woman will be cured by the operation of trachelorrhaphy. If such a repair is practiced the symptoms continue. In such cases of long standing laceration the secondary changes in the cervical tissues become permanent in character. The cystic degeneration becomes too wide spread, the inflammatory induration or fibrous connective tissue too well established to yield to any treatment. Here the operation to be selected which alone will cure the woman is amputation of the cervix. Therefore, in extreme cases the preparatory treatment to which I have alluded is of advantage in enabling us to determine the best method of operation to pursue. If the condition of the cervix improves, the woman can be cured by trachelorrhaphy; if it does not improve we shall be obliged to resort to amputation. It should not be forgotten that the mere closure of a tear of the cervix, even though union may be perfect, does not always cure the woman. It will not cure her of the cystic degeneration, and the sclerotic condition persists. I have a number of times amputated the cervix for these conditions when a bilateral laceration had been closed, well and successfully as far as the mere surgical result was concerned. The woman after the first operation continued to suffer with all of the symptoms presented before the trachelorrhaphy.

In regard to the details of technique of the operation of trachelorrhaphy I will only allude to a few important points. In making the denudation great care should be taken to remove all cicatricial tissue, carrying the excision well into the angles of tear on each side. The finger should be passed over the surface to determine indurated areas, which should be caught with a tenaculum and excised. No portion of a wall of a Nabothian cyst should be left in the line of denudation. The excision of tissue should be done as nearly as possible in the plane of laceration. A frequent mistake is to remove too much tissue from the vaginal aspect of the cervix.

The sutures should be accurately and evenly placed. In introducing each suture a large amount of the tissue underlying the denudation should be included, so that the needle describes a complete circle when introduced through both lips. If introduced through a small amount of tissue and simply a short distance beneath and parallel with the plane of denudation accurate apposition cannot be secured. The first suture should be introduced well up into the angle of tear, best at the angle of tear, to secure bleeding and prevent fistulae here. A mistake which is very often made, occurrence of which destroys any benefit that might be derived from the operation is, in introducing the needle, it is made to emerge upon the denuded surface. When this occurs the suture does not include in its embrace the whole of the denuded area, and after union has taken place the condition which has been described as incomplete laceration is produced: the cervix is closed to all external appearance, but has a canal, perhaps two or three times as broad as normal, bounded on each side by little more thickness of tissue than the mucous membrane of the vaginal aspect. The result is persistence of the sub-involu-

tion and a cervical endometritis which will yield to no treatment except another operation. The suture should enter upon the vaginal aspect of the cervix, as said, pass around the whole of the denuded area, and emerge in the edge or slightly within the mucous membrane strip which has been left for the cervical canal. The sutures should not be too tight, nor too loose, but of sufficient tension to secure accurate and firm apposition. If there is too much tension they cut out and the same incomplete tear is apt to be produced. If the apposition is not even and accurate or the suture is too loose, again the same condition of incomplete tear results or fistulae are formed.

If good asepsis is practiced union will never fail. In at least seven or eight hundred trachelorrhaphies I have never seen union fail. An infection of the cervix after operation or a failure of union is an unpardonable mistake in this operation. During the last few months, however, I have had three patients referred to me in which no union had taken place. In one I was able to do the operation of trachelorrhaphy again, but in the other two amputation was necessary.

I remove the sutures at the end of two weeks if trachelorrhaphy alone has been done, but if this is combined with perineorrhaphy the sutures are removed at the end of three weeks. The greatest care should be taken not to cut off both ends of the suture leaving a loop of silkworm gut in the cervical tissue. In the two cases I have just referred to where amputation was practiced such a loop was removed. It no doubt had much to do with the chronic inflammatory change, indurated condition of the cervix which compelled me to do the operation of amputation.

Finally, gentlemen, permit me to call your attention to the importance of diagnosing as early as possible between bad laceration of the cervix uteri with sclerosis and eversion of the mucosa, and beginning carcinoma of the cervix. Carcinoma of the cervix in practically all cases occurs in an old laceration. All statistics show this. Carcinoma of the cervix is a disease of the childbearing woman. For this reason I think all, except the slightest, lacerations of the cervix uteri should be closed; so that when the woman reaches the menopause, the age of greatest liability to carcinoma, the cervix may not present a spot of least vital resistance favorable to the development of the disease. But this is prophylactic medicine. Contrasted with these cases are those in which carcinoma has already begun in an old laceration. The cases on the border line between chronic, deep seated, nonmalignant diseases of the cervix, the result of laceration, and the earliest stages of malignant disease. It is of the greatest possible importance that we recognize these cases early. I cannot overrate or too strongly impress you with the importance of this early diagnosis. Upon it depends the life of the woman. It is now true that if carcinoma of the cervix is recognized early, if possible at the time of appearance of the first nodule, or even when it is still confined to cervical tissue, the operation of pan-hysterectomy promised cure in the majority of cases, surely in the very earliest stage. While, if the diagnosis is de-

layed for a few weeks or months, the case becomes hopeless with our present surgical methods.

If the physician has even the slightest suspicion of malignant disease in the case of laceration of the cervix uteri, he is in my opinion a criminal if he idly waits developments. The slightest bleeding in the intra-menstrual period or an excessive bleeding at the menstrual period of a woman in the latter part of sexual life, any excessive bleeding at the menopause or slight or excessive bleeding after this time always suggests, gives rise to a suspicion of carcinoma and examination is imperatively demanded. There are two methods by which the early diagnosis may be made. If with local treatment, as puncture, tincture of iodine, glycerine and douches, the condition improves and the suspicious appearance disappears the disease is not beginning carcinoma. Or we have even a quicker and surer test by microscopical examination of a portion of excised tissue. The suspected tissue or nodule should be caught with a double tenaculum and a wedge shaped piece cut out with curved scissors which shall include the mucosa of the cervical canal, the mucosa of the vaginal aspect of the cervix and a mass of the underlying stroma tissue. Be sure that it is of sufficient size to include these tissues, particularly sure that it includes the suspicious nodule. This procedure is practically painless, there is little or no bleeding, and it can be done without either. The latter method is the one I employ because a microscopic study is easily within my reach, I make it myself, it requires but a day or two at most, is more certain and has so frequently saved the life of a patient for me.

I dwell upon this point in speaking of laceration of the cervix because most women with carcinoma of the cervix die of the disease, and these horrible deaths, as shown by the history they give me, is so often the result of the neglect of a family physician. The diagnosis many times could have and should have been made early.

A REPORT OF TWO CASES OF LYMPHANGIOMA.*

By VERTNER KENERSON, A. M., M. D.

Instructor in Clinical Surgery and Bacteriology, at the University of Buffalo; Attending Surgeon, Erie County and Riverside Hospitals; Assistant Surgeon, 7th Regiment, New York National Guard; Late Acting Assistant Surgeon, U. S. A.

In January, 1896, Louis Schultz, 12 months old, of German parentage, born in New York City, was admitted to the Wards of the New York Hospital for examination and treatment.

The child's birth was normal, and no history could be obtained from the mother of any unusual prenatal influence. The mother was a well-nourished, German-born woman; hard working, somewhat neurotic, about 30 years old, and this was her first child—after three years of married life.

The patient, on admission and examination, presented a smooth, somewhat venous, dusky tumor, involving the whole left side of the face, with gradually sloping edges. The mass was firm, did not "dent" on pressure, was closely adherent to the underlying structures, and to the overlying skin. It did not pass the median line, did not fluctuate, was not tender, and could be manipulated without disturbing the child.

The mother gave the following history: The child had been born, so far as she could explain, by a normal delivery, without forceps, and labor pains extending over 12

hours. Her recovery was uneventful, and she had nursed the child up to the time of admission. The tumor had given no inconvenience, and had first appeared or had been noticed a few days after birth.

She described the appearance as if the whole of the left side of the face had appeared somewhat thicker than the other side.

At the time it was first noticed—a few days after birth—the overlying skin was not discolored much, and they were not much worried by the appearance. The whole area was slightly involved when first noticed.

Figure 1 Lymphangioma

This whole area had, during the first 12 months, become gradually involved for a greater depth, and the tumor had become firmer in consistency, and was more discolored. The parents wished to have something done to stop the growth. A consultation was held, and operative interference was deemed inadvisable because of the age of the child, and, no urgency seeming evident, a delay was counseled until the child was weaned, and patient was accordingly discharged, and the mother was told to return. The patient was readmitted July, 1896.

During the intervening period the child had been weaned, and remained healthy, was not irritable, and ate ordinary children's food. The lun or had had a constant slow growth for the first 5 months after the previous examination, and then during the last month the growth had been very rapid, the growth being especially noticeable in the pendulous portions of the tumor—namely the parts corresponding to the eyebrow and inferior border of the cheek over the ramus of inferior maxilla. The tumor now extended, as before, from the median line, displacing the nose and mouth toward the right side of the face, and involving the whole left lateral aspect, closing completely the left eye and almost entirely closing the left nostril.

The skin was tense and was colored a dusky bluish tint; the whole tumor was firm, resisting, closely adherent to underlying structures, and to the overlying skin. The growth was confined to the structure outside of the skull. The tongue, left eyeball, mucous membrane of nose and mouth were not involved.

There was fluctuation over the dependent parts, which had been evident since the sudden increase in growth. The child slept well, was cheerful, ate well, and the bodily functions were regular. There was no general cachexia, and there was no elevation of temperature or pulse.

The rapid growth in the last month indicated a change in the process. The lymph spaces were all enlarging rapidly, and fluctuation was due to lymph. It was deemed advisable to try skin-electrolysis. Accompanied by a great deal of discomfort to the patient, this was applied, after previous sterilization of the skin by a weak solution of carbolic acid. Two needles were introduced into the tumor, one at a short distance from the other, and then the current was turned on, which was a weak one, and allowing it to remain for one to three minutes.

Several double punctures were made at each sitting, and a sitting was arranged for on alternate days.

These electric treatments were persisted in for four sittings, and then because the sight of the apparatus created such a disturbance, two more treatments were made under chloroform.

*Read before the Surgical Section of the Buffalo Academy of Medicine, Buffalo, New York.

After each puncture, the small hole left by the needles exuded some serum, and after this was wiped away the punctures were covered with flexible collodion and a wisp of cotton.

The punctures were made vertically into the tumor, the needles being introduced about one inch, and at right angles to the surface of the tumor.

This work was done carefully under surgical cleanliness, and every effort was made not to infect the punctures in any way. The point of application was over the dependent fluctuating portion of the tumor involving the cheek, and possibly in the disturbance which the pain caused the child to make some of the punctures may have entered the mouth, and infection may have been carried in that way.

From whatever cause, the punctures and that portion of the dependent tumor became infected, quite a local central slough ensued, and a considerable constant watery fluid was exuded, and the process of electrolysis was discontinued.

The portion above the eyebrow seemed separated by a ridge from the cheek portion, and it was decided to operate, removing (if possible) a portion of the tumor at one operation and the remainder at a second operation. Accordingly, Dr. Francis Murray operated July 10, 1896. He made an incision at the junction of the tumor with the normal tissues in the median line of the forehead, extended the incision upward and back, dissecting the mass from the muscular and perosteal attachments down to the supra-orbital ridge. He then dissected from the outer surface enough of the skin to cover the denuded surface, replaced the same, suturing and closing the wound, leaving plenty of drainage. The tumor had been cut around, except the thin isthmus which connected it with the lower part of the tumor. The tumor looked venous, and it was expected the operation would be very bloody, but comparatively little blood was lost, but there was a constant and heavy loss of serum or lymph.

The child did not suffer much from shock, but the temperature promptly went up and remained up until the ninth day, when the child died.

There was no pus, but a constant loss of lymph, most of it apparently coming from the lower edge of the wound, where a section of the connection with the lower and largest part of the tumor had become necessary.

The lower wound, when there had been an attempt made to treat the case by electrolysis, continued also to discharge, and what pus there was (and that was little) came from that opening.

The tumor was made up, not of many blood vessels, as its surface would indicate, but of lymph spaces, irregular, with apparently a multiplex structure of fibrous tissue.

The meshes of this fibrous stroma were coarse, and the lymph spaces were apparently lined with a thin lining of smooth cells. The spaces were very irregular in size, and varied from those that would admit the tip of a probe to those that would admit—when a section had been made—the tip of one's little finger.

The drains that were left in situ (which were of iodoform gauze) were literally washed out, and, when the wound was dressed on the 2nd day, new drains were inserted and some of the sutures were renewed.

A careful dissection was made, hoping in this part of the tumor to find the afferent trunk of the lymphatic which caused the disturbance and supply for the tumor, but it was not found.

The dissection was made down to healthy underlying tissue, except at the lower edge, where a cut through the thinnest flattened portion of the tumor was made necessary by the plan of removing only part of the tumor at the first operation.

The case, and the causes and results, first and last, were much discussed at the time, and it was thought by the operator, Dr. Murray, that if he had been able to have removed the entire mass, without causing death from shock, somewhere probably just in front of the ear, where the lymphatics emerge from the skull, there would have been found an afferent trunk supplying the mass, which could have been tied in solid muscular or fibrous surroundings, that the ooze could have been stopped, and healing made possible.

Case 2. Came under my care about 5 months ago.

Child, 5 months old, personal and family history uninteresting, except cause of application for treatment, namely, lymphangioma of neck. Child was born (third child), normal delivery, without evidences of abnormality, but growth appeared about the second week of life. The tumor in this case was located at the junction of the shoulder and neck on the right side, filling in the shoulder notch as high as the level of the lobe of the right ear.

The tumor was not painful. The child was well nourished, fed on the breast; the mother was an Italian, and of a nervous disposition.

The tumor was firmly adherent to the upper angle of the scapula and the muscle of the back and neck extending from the median line of the junction of the shoulder and neck around to the right, well into and filling the supra-clavicular space.

Figure 11. Lymphangioma.

The tumor was a dingy, bluish color, firm, not fluctuating, firmly adherent to surrounding structures, no pulsation, and no local point of tenderness. The mother said the recent growth had been rapid, but the general health of the child remained unimpaired.

After making careful preparations for the rapid completion of the work when once under way, I determined to try and remove the tumor *en masse* and ligature the afferent trunk supplying the lymph in solid surroundings, meanwhile supplying the child's economy, as much, or more, hot salt solution as was eliminated by the operation, the loss of blood being inconsiderable in the previous operation.

The child was carefully prepared in the usual way, by applying a green soap poultice for a short time, then washing carefully and yet faithfully with a coarse cloth, and rubbing with bi-chloride solution 1/2000, finally rinsing with alcohol and ether, and binding in situ a compress covering the tumor and surrounding parts with bi-chloride 1/2000, and leaving in place until the moment of operation. The child was given no depleting physic, and was nursed up to within three hours of the operation.

The operation was performed in a very warm room (hot, I may say), and with hot water bottles packed around the child, and with four assistants and two nurses.

Preliminary to the operation, I prepared 1000 c.c. of normal salt solution, which was sterilized, filtered, and then sterilized three consecutive days. It was sterilized in a receptacle from which it could be used intravenously without transfer, namely, in a glass irrigator, stoppered and supplied with rubber tubing, etc., including silver-

tipped canula, these all carefully cleansed and sterilized at the same time. The tumor was on the right side, and accordingly the left arm was prepared for intravenous injection of salt solution 6/10 of 1%.

Before beginning the operation, I made an incision over the median basilic vein of the left arm, introduced a small ligature carrier under the vein, carrying a double ligature, which was then divided, the carrier withdrawn, and the distal half of the ligature tied tightly, and it was then used as a guy to control the vein while being opened, and the canula inserted. I knotted, but did not tighten the proximal ligature until the vein was opened, which I did longitudinally, with a fine but very sharp-pointed scalpel, and then the canula was introduced, flowing at the moment of introduction with normal salt solution, temperature 115° F., and the proximal ligature was then tightened around the canula, which held it gently in place, and the whole was wrapped around with warm towels, and entrusted to an assistant. The flow was controlled by the assistant (Dr. LeBreton). About 150 c.c. of salt solution was allowed to flow into the veins of the child before any operative procedure was begun.

Figure III. Lymphangioma.

The child was given as little anesthetic as possible, and the operation was begun, with the necessity in mind to avoid as much as possible the shock of a prolonged operation, and yet reach the afferent lymphatic trunk supplying the tumor where it emerged from the body cavity and tie the same securely on the body surface.

An incision 5 inches long was made around the posterior margin of the tumor, and the whole tumor was rapidly dissected away from the underlying muscle and scapula, and, when the line of demarkation was not exactly evident, another piece of muscle was removed, rather than leave any portion of the lymphatic tumor. The afferent trunk was found in the supra-clavicular space and tied. The tumor weighed 12 ounces, and was removed with its attached skin, leaving an uncovered area 5 inches long and 1½ inches wide, tapering to an apex at each end. The entire operation, including the suturing and drawing the skin over the raw surface with tension sutures, occupied less than 15 minutes, and an almost constant flow of salt solution was maintained by the assistant in charge of that work, the child receiving 600 c.c. of salt solution at a temperature varying but little from 115°. The most rapid work consistent with safety and security was carried out.

The child died from shock.

Both of these operations were undertaken after the true nature of the case had been ascertained, and the extreme gravity of the operation understood, and had been explained to the parents.

The affliction in these cases is very great, the children are really monstrosities. The tumors increase as they grow older, and they are not enabled to secure employment except in disagreeable businesses, and the gravity being understood the operations are warranted.

There has been comparatively little—almost nothing—done by way of recording operative suc-

ses or failures with these cases, and little—if anything,—is known of the etiology of these lymphangiomas.

I examined each of these tumors microscopically, and appended drawing of the microscopic appearance.

The section in each case involving the skin and showing the lymph spaces. When these sections are stained with silver salts, the endothelial character of the lining membrane is clearly seen. The tumors are usually congenital, although they may occur after trauma and disease late in life, seldom developing after puberty. They are to be distinguished from Elephantiasis as being limited in area and seldom involving a limb, and never passing the median line, although they may be double and not connected. They are usually directly connected with the deep lymphatics of the trunk, and, in the literature, I found two cases recorded where lymphangioma had been mistaken for inguinal hernia. The most frequent seats of the disease are the inguinal region, (not involving the extremities), the tongue, the lips and neck and supraclavicular spaces, sides of face and skull. They are in character benign. The history is usually given that the children have no deformity at birth, but some slight abnormality is noticed within the first few weeks, and a steady, slow, painless growth may be expected for some months, and perhaps years. Most cases eventually take on a sudden increase in rapidity of growth and through mechanical means become unwieldy, later poorly nourished and frequently break down and suppurate or discharge, after which stage the decline is rapid.

When there is only a superficial involvement and the tumor remains for a considerable period of slow growth, and the parts are not pendent, the method of occlusion by electrolysis is undoubtedly the method most to be recommended. But to make this effective, application must be made at short intervals for several months and perhaps years, and at each application an anesthetic is necessary. In the rapidly-growing, pendent tumors, or those connected with internal lymphatics—as they most of them are—either on the breast or at the upper or lower openings of the thorax and abdomen respectively, the electrolysis will be found entirely inadequate, and the rapid growth will more than make up for the slight retardation made by a single application. The use of caustics, irritating fluids and Pacquelin's cautery have not recently been, and should not be used. In the operative procedure, there remains to be counteracted the element of shock which is very great in these young cases. The afferent branch connecting with the internal lymph supply must be found and securely tied. Children stand Major surgery rather poorly and these tumors begin to grow rapidly and necessitate early interference, and the risk is consequently greater.

I find no record made of the fact in the literature, but in these two cases there was certainly a similar neurotic tendency in the maternal parent. The maternal parents were both not "favored" with contentment and worldly goods, were parents late, —that is, approaching 30, were hard working, and the tumors in the children were undoubtedly con-

genital. They, however, had, so far as could be ascertained, normal deliveries with not over-prolonged labors, and the children appeared normal at birth. The etiology of these tumors has received little or no attention; or, if so, they have been recorded in unusual places.

Dr. Councilman says, in a general way, that it is supposed they are caused by a congenital or acquired occlusion of the efferent trunk of a set of lymphatics which supply a particular part. This seems plausible, but he does not submit any facts in support of his plausible theory of how or why occlusion occurs. He also adds that most of the spaces are simply normal lymph spaces much enlarged by continued pressure and hypertrophy of surrounding supporting fibrous tissue. The tumors look venous, but usually contain but little blood. When the tongue is the seat of the affection, it may be so great as to force the tongue from the mouth. The peculiarity is marked in cretins who are frequent objects of attack. I believe if these tumors are taken early, under proper precautions they may be operated upon with safety. The deformity appears to do no injury, except when it involves, outside the trunk or skull, the subcutaneous connective tissue and skin. There should be future histological and pathological microscopical work to determine what difference exists between these external lymphatics and the internal lymphchannels.

THROMBOSIS OF THE CAVERNOUS SINUS.—DOUBLE PANOPHTHALMITIS OF SEPTIC ORIGIN.

By EDWARD JACKSON, M. D.,

of Denver, Colo.

It is rare, in rapidly fatal disease, to have the ocular symptoms overshadow all others; and give the most positive and valuable evidence of the impending danger to life. The following cases were of this character. They occurred at the Arapahoe County Hospital, during my last term of service; and were at first regarded by the internes as cases of purulent conjunctivitis, a diagnosis that had a good deal to favor it. As the anatomical conditions were ascertained by post-mortem examination, they seem worthy of record.

CASE I. *Thrombosis of Orbital Veins Extending to Cavernous Sinus.* J. C., male, aged 26, a native of Ohio, suffering from pulmonary tuberculosis, was admitted to the medical service of Dr. H. B. Whitney, January 3, 1901. He had suffered from a hemorrhage in 1897, and with cough and expectoration since that time. He had been somewhat worse the last few months—was weaker, and had suffered from asthma. But he was not greatly emaciated, and gave no indication of an early, fatal termination of his case.

During his first five days in the hospital, his temperature did not rise above 99.5. Respiration ranged from 24 to 42, and pulse from 100 to 138. His urine was rather concentrated, specific gravity 1030, but otherwise normal. On the night of January 8th, the lids of the right eye began to swell. There was slight muco-purulent, conjunctival discharge, and severe pain in the region of the right orbit.

January 9th.—The patient was transferred to my charge, and when I saw him in the afternoon, there was great swelling of the right lids, some protrusion of the eye, severe muco-purulent conjunctival discharge, no marked impairment of the ocular movements, cornea normal and

vision apparently unaffected. The left eye had already been protected from supposed risk of infection by discharge from the right by a Buller's shield. It appeared normal in all respects, and remained so throughout the case. The temperature, which had risen the preceding night to 101°, had dropped again to normal; pulse 120; respiration 30. Repeated microscopic examination of the conjunctival discharge failed to reveal either the gonococcus or the Klebs-Loeffler bacillus. The patient made no complaint except of severe aching in the region of the orbit.

January 10.—The swelling of the lids, chemosis, prominence of the eyeball and conjunctival discharge have increased. Temperature rose to 100.5° in the afternoon, with pulse 108, respiration 20.

January 11.—The swelling was still greater. The cornea remained clear, vision apparently good, and there was no impairment of the ocular movements, other than would be accounted for by the orbital swelling. The temperature, 101.4° in the morning, rose to 102.5° in the evening. There was continued complaint of pain and slight delirium. The patient died on the 12th, quite suddenly, shortly after midnight, having responded rationally to questions a few minutes before.

The treatment employed was frequent washing of the eye with a 2 per cent. solution of protargol, and the application of a 20 per cent. solution of protargol, once daily. Internally calomel and a saline were given, with morphia to diminish the pain.

The post-mortem examination was made 14 hours after death by Dr. J. A. Wilder, pathologist to the hospital. It showed old lesions and scattered tubercles in the upper lobes of both lungs; with moderate recent congestion and edema. The heart, spleen and kidneys were normal; there was a nutmeg liver. The cerebral meninges showed miliary tubercles scattered over both hemispheres, but none at the base of the brain. In the right cavernous sinus was an organized clot, about 1/8 of an inch in diameter, extending into it from the orbital vein.

In the early part of its course, this case looked more like one of purulent conjunctivitis than anything else, although the excess of swelling and rather moderate discharge caused me at first to think it might be diphtheritic. The movements of the eye showing no impairment except such as would be expected from the swelling, at first seemed to exclude thrombosis of the cavernous sinus. Later, the swelling of the orbital tissue showed that it was in some way involved; but not until the case had run its course did I conclude that it was a case of sinus thrombosis.

The clot found extended into the cavernous sinus from the orbital vein. But, even allowing for post-mortem contraction, had probably not filled the sinus; and it presented no prolongations extending into other cerebral sinuses. It seems probable that it originated in some vein in the orbit. This would account for the absence of any early paralysis of the extraocular muscles. The vision retained until the time I last saw him, a few hours before death, showed that the thrombosis had not then involved the retinal vessels.

CASE II. *Double Panophthalmitis and Septicemia from Abscess of the Knee.* P. P., female, aged about 45, a light mulatto, a native of South Carolina, was admitted to my service January 25th, 1901. The only history obtainable was of inflammation beginning simultaneously in both eyes nine days previously. Within five days she had become absolutely blind. She was said otherwise not to have been sick; but we subsequently learned that she had been ailing for a couple of weeks. The left knee was somewhat swollen and painful; and there were several large blabs on the right foot and ankle. There was a fetid, purulent discharge from the vagina, but the patient denied any history of venereal disease. Repeated examinations failed to reveal the gonococcus in either the conjunctival or vaginal discharges.

On admission her temperature was 99.5° and pulse 120.

The pulse did not rise above this; respiration continued at 24, and her temperature did not again go above normal, until a few hours before her death, when it rose to 102°.

There was no rigor and no excessive sweating. The urine contained some pus and some granular casts, and had a specific gravity of 1014, but was fairly abundant. The patient's mental condition was apathetic. She continued conscious until just before death, and answered rationally, but quite sluggishly, the questions put to her. She insisted that there was very little the matter with her except her eyes; and blamed the doctor who had first attended her for her loss of sight. She gave no evidence of pain except when the swollen knee or one of the eyes was pressed upon.

The lids were moderately swollen. The conjunctiva was extremely chemotic, folds of it protruding between the lids. Both eyes were absolutely blind with all the evidences of panophthalmitis. The conjunctival discharge was quite moderate. The corneas were but slightly turbid. But there was some pyopyon and extensive suppuration back of the lens. The right eye showed tension + 3. The left eye was soft, the cornea having been perforated near its lower margin, allowing free exit to pus from the interior of the eye.

The inflammation had so clearly arisen from the posterior segment of the eye-ball, indicating a probably embolic, septic origin, that my colleague, Dr. J. N. Hall, was at once asked to see the patient. His careful examination revealed only a few minute, petechial hemorrhages, which he regarded as also pointing strongly to a septicemia. The treatment of the eyes was confined to cleansing with a 2 per cent. solution of protargol. The patient's condition remained practically unchanged until the morning of the 25th, when the signs of commencing septic pneumonia were found by Dr. H. B. Whitney. She died at 2 P. M. that day.

Postmortem examination made by Dr. J. A. Wilder, showed decided hypostatic pulmonary congestion, but no solidification. The heart and great vessels were normal. The uterus and appendages were normal. The only origin discovered for the septicemia was in the left knee joint, which was filled with pus. The right kidney was normal, the left was slightly enlarged, and its capsule stripped with some difficulty.

In this case, although it came into the hospital as one of purulent ophthalmia, the appearance of the eyes at once demonstrated that it was a purulent retinitis or choroiditis, which from its character and simultaneous involving of both eyes, must almost certainly have arisen from grave septicemia. Although the temperature and general symptoms gave little assistance in the diagnosis, the eye symptoms seemed sufficient to make it fairly certain from the first.

The origin of the sepsis, however, was only cleared up at the post-mortem examination. Up to the time of death, although no physical signs of it were discovered, a septic endocarditis seemed the most probable explanation. A possible focus of infection in the genital organs was also thought of. The absence of distinct uremic symptoms and the fairly good general character of the urine led us rather to exclude kidney disease as an important factor in the case; and the post-mortem examination showed no grave organic changes in the kidneys.

A Case of Absence of the Pulse in the Arteries of the Left Arm.—S. I. Schvartz (*Medicinskoje Obsrenie*, June, 1901) observed a case in which no pulsation of the radial and ulnar arteries could be detected. The patient, a girl of 20, was of a nervous temperament and of a neurotic family. She had had at one time paralysis of the left hand accompanied by hyperesthesia. This affection disappeared suddenly after a man grasped her forcibly by the hand to save her from an impending fall. The author ascribes the absence of the pulse to nervous spasm of the walls of the blood vessels as a result of hysteria. [A. R.]

ONE MORNING'S WORK WITH STOMACH CASES: ETC.

By BOARDMAN REED, M. D.,

of Philadelphia

Adjunct Professor of Hygiene Temple Medical College.

There are possibly still physicians in practice who look upon dyspepsia as an entity which is always practically the same thing—that is, a condition of imperfect digestion to be met by the prescription of stimulants, condiments, pepsin and HCl. If there are still such practitioners, the following reports of cases, most of which were seen at my office upon a single morning in April last, will likely surprise them, and should certainly interest all physicians:

CASE 1.—Lady from Boston, Mass., aged 56, who consulted me here first three years ago and was found to have chronic atrophic gastric catarrh. The total acidity of her stomach contents was 13, as against a normal of 50 to 60, and there was no free HCl an hour after the Ewald breakfast. Mucus, large amount. The stomach itself was in a condition of gastropexia with some dilation, the upper boundary of the fundus being two inches above the lowest rib in the left parasternal line, and the greater curvature two inches below the level of the umbilicus. She had been afflicted from birth with a chronic form of constipation. She was placed upon appropriate treatment and returned home a few days later. Her first visit to me was chiefly on account of the ill health of her daughter who was then under my care. On returning home she was so engrossed with family cares and other duties, that she soon abandoned all efforts at treatment. She returned to me recently because in addition to her stomach symptoms, she had developed a serious form of chronic arthritis rheumatoid in type, and suspected that it was in some way connected with her chronic gastrointestinal troubles, as it most probably is. I found her with the stomach externally in the same condition as before, except that the gastric contents one hour after the Ewald breakfast showed a total acidity of only 11, no free HCl whatever, and the percentage of combined HCl .014 as against a normal of .050 to .070. She was otherwise in worse health than before, her nerve tone being greatly lowered and her joints, some of them, so stiffened that they could scarcely be moved. She had been, during some months, under medical care in Boston, but no special examination had been made of her digestive system and there had been no urinalysis. The urine, on being carefully examined here, showed that the percentage of urea was only 1.51, indicating a faulty metabolism, which goes far toward explaining the malnutrition and joint trouble. I have just learned (Sept. 5) that she has been under treatment in Boston for her joint affection during the past summer, and is about the same.

CASE 2.—A physician, aged 35, came under my care in January, 1900, suffering from acute pain several hours after eating, which was relieved by pressure and by taking more food. The physical examination showed him to be sound in all respects, except that upon analysis of the stomach contents an hour after an Ewald breakfast, the HCl proved to be in very large excess. The total acidity during the first few weeks of treatment was from 62 to 98, and the free HCl ranged from .160 up to .208, as against a normal of .050 to .070 in spite of large doses of alkalies and belladonna. He was in active practice, not being able to rest during treatment as he should have done, and, finding other measures ineffectual in his case, I treated him with the high tension faradic current applied directly to the inner walls of his stomach by my modification of the Einhorn intragastric electrode. After a month of this treatment he lost all symptoms and the percentage of free HCl, though much reduced, was still not normal. However, he felt so well and was so busy that he gave up treatment, declaring himself in as good health as he had ever been, so far as he could judge by his feelings. That April morning, after being one year without treatment, he returned to have another test made on account of a recurrence of gastric discomfort and pain. Upon testing his stomach contents we found again an enormous excess of HCl. The total acidity was 92, the free HCl .233, and yet the combined HCl was only .058 as against a normal of .060 to .070,

thus confirming many previous observations that in hyperchlorhydria peptonization is often lessened rather than increased above the normal. In this doctor's case there was, and still is some proliferation of the gastric cells, though there has never been a large excess of mucus in the stomach. His unusual resistance to treatment would render it probable, however, that a proliferative process had been set up, since in all cases where the affection is purely neurotic, there is a prompt response to alkaline and sedative treatment—at least prompt curative results usually follow such a treatment when the patient can observe the proper hygiene. A professional man, obliged to continue in the active pursuit of his calling, might well resist any treatment. This patient responded again promptly to the high tension faradic current applied intragastrically.

CASE 3.—A prominent business man of Philadelphia, aged 44, consulted me in February, 1900, and was found to have a liver slightly enlarged and a stomach dilated to one half inch below the level of the umbilicus. He was in a nervous, overstrained condition, with much impaired sleep, being under an extreme mental tension on account of a multiplicity of important business affairs. The analysis of the stomach contents one hour after the Ewald breakfast showed the total acidity to be 82, the free HCl .211, and the combined HCl .043—another confirmation of how a very large excess of HCl may coexist with a deficiency of peptonization, as shown by the proportion of that acid found combined with the albuminoids of the food. He resisted drug treatment and only responded slowly to the high tension faradic current applied with the intragastric electrode. In his case also it was impossible, he thought, to give up his business and rest. Notwithstanding this, he improved considerably, and at the end of about one month the total acidity was .109 and the free HCl had fallen to .141, not enough stomach contents being obtained to make the extra test for the combined HCl. There was much mucus in his stomach at the beginning, and some proliferation of the gastric glands, as in the previous case. On the 29th of March last he returned to me, having had no treatment meanwhile, since he considered himself well enough to do without. He had been carrying on his extensive business during the entire interval, except that he had had a vacation during a part of the summer. He was again put upon gastric sedatives and alkalines, together with an order to return every other day for intragastric faradization, but after two treatments of this kind, was prevented by business from making other visits to my office, and to-day, upon his return, nearly a month later, I found naturally only a small falling off in the hyperacidity. The total acidity was 88, free HCl .197 and the combined HCl .124. At present he has almost no complaints to make subjectively, feeling well and getting good sleep. Yet I realize that his stomach is in an abnormal condition, and that notwithstanding the present apparent tolerance of the very excessively acid secretion, there is great danger that, unless he perseveres with appropriate treatment, his nervous system will again be seriously impaired and in addition to a chronic acid gastric catarrh, a chronic enteric catarrh ultimately result.

CASE 4.—Merchant, aged 38, consulted me first in February, 1898, on account of extreme nervous depression. This upon inquiry was proved to result from a variety of causes which need not be detailed fully here, but prominent among the conditions found was a condition of hyperacidity from hydrochloric excess with large amount of mucus in the stomach, indicating a beginning acid gastritis. He was also very lithemic. Appropriate treatment, both medicinal and electric, directed to the stomach condition as well as to the entire nervous system, rapidly improved him. The mental depression which had brought him to the verge of melancholia, disappeared, and by the end of three months he declared himself to be feeling perfectly well. For a long time past he has had no regular treatment from me, though once or twice since the time before referred to, he has had some slight recurrences of mental depression, due to lithemia. He called in on the same day before referred to, in order to let me look him over before my departure from the city for a long absence, and I found him in almost his normal condition, though complaining of being a little nervous at times.

CASE 5.—Maiden lady, aged 54, residing in a suburb of New York city, came on with her near relative, Case 1, to see me. She had been in previous years frequently under my care because of a marked derangement in her gastric

secretion (laterly hyperchlorhydria) and other digestive and nervous troubles dependent for the most part, as I finally decided, upon a movable right kidney. After the operation of nephropexy, done at my instance by Dr. E. E. Montgomery, she entirely recovered her health. At her visit on the day above mentioned I tested the stomach contents after the Ewald breakfast with the following results: Total acidity 43, free HCl .076, combined HCl .025. A very little mucus, evidently from the throat. No indications of excessive organic acid. The comparatively low total acidity and small amount of peptonization, as shown by the very low figures for the combined HCl, point to a probable deficiency of pepsin, and I therefore prescribed 15 drops of Parke, Davis & Company's Glycerine of Pepsin in water after each meal. A letter from her, received at the time of writing this reports that she is entirely well except an occasional bilious attack from overeating.

The above reported cases seem to tell their own story and scarcely require comment. They certainly demonstrate that it is not safe, and especially not just to patients, to prescribe for their digestive disturbances, or for the nervous derangement, wholly dependent upon or at least complicated with disease of the digestive organs, without investigating by the modern exact methods the condition of the latter.

JOURNAL DES PRATICIENS.

August 3, 1901. (15me. Année, No. 31.)

1. A Case of Irreducible Femoral Hernia without Symptoms. ED. SCHWARTZ.
2. Psychotherapy in the Treatment of Neurasthenia.

MAURICE de FLEURY.

1.—Schwartz reports the case of a woman of 48, with a chronic bronchitis. While coughing, she felt a slight pain in the right groin, and, on examination, found a small femoral hernia, which remained irreducible. There were no symptoms, the tumor remaining about the size of a small egg. Operation was performed 48 hours after the hernia appeared, and the small intestine was found tightly pinched by the femoral ring. This was reduced, and the operation for radical cure finished. She recovered rapidly. He recalls a similar case in which operation was not performed early, death occurring immediately after the operation. Though it is rare to find a case of femoral hernia which has the small intestine simply pinched laterally, operation should be done immediately. [M. O.]

2.—To treat neurasthenia well, a physician should have had it himself, thinks de Fleury. He must have patience, talk to the patients, listen to their tales of suffering, take an interest in them and their doings, and so encourage them. Most important of all, he must be sure of his diagnosis, and must know whether the patient is a neurasthenic with hypertension, or one with hypotension. In the former case, a diet of milk and vegetables, massage warm baths, hypodermic salt solution injections, exercise, etc., will be indicated. In the latter, rest with good food, tonics, fresh air, and later graduated exercise, is needed. Here, too, saline injections will help. When neurasthenia has existed for some time, the mental condition of the patient may show a quasi-independent personality, with fixed ideas. Here especially does hypnotic suggestion work wonders. Some regular physical exercise and some progressive mental work are both necessary to occupy the returning nervous strength of the neurasthenic. The patient can be isolated at home, unless very ill. Rest for the neurasthenic with hypotension is needed at first, later exercise can be begun. In the neurasthenic with hypertension, exercise should be begun at once. When the patient shows excitability or enervation, begin some intellectual pastime. Overfeeding should never be given a neurasthenic with hypertension, but may be of value in treating one with hypotension, early in the case. A voyage will distract the neurasthenic with fixed ideas, melancholia, etc. But to treat neurasthenia successfully, the physician must have the entire confidence of his patient. [M. O.]

\$3.00 PER ANNUM

The Trial of the Assassin.—In his celebrated defence of Hadfield, for shooting at the King, Lord Erskine said: "The scene which we are engaged in exhibits to the whole civilized world a perpetual monument of our national justice. The transaction, indeed, in every part of it as it stands recorded in the evidence, places our country upon the highest pinnacle of human elevation." These words of the greatest of forensic orators have not lost their significance after the lapse of a hundred years and in the midst of a different and distant phase of Anglo-Saxon civilization. Erskine spoke for the supremacy of English law as against the turbulence of popular passion, and his language applies with great force and precision to the sovereignty of American law as it has just revealed itself in the trial of the assassin of the President.

From the medico-legal standpoint, however, it cannot be said that the trial of Czolgosz equals in interest and importance the trial of Hadfield. In fact it can hardly be claimed that the case of the President's assassin had any medico-legal aspect, whatever. If it had any such aspect, this was most successfully kept out of public view in court. The trial of the case, which from the purely legal standpoint was, we should judge, perfect in its form and setting, was on the other hand singularly barren and un instructive for all the purposes of medical jurisprudence. This can hardly be because the case was really lacking in all elements of medico-legal interest, for the eminent counsel for the defence had no sooner come from the trial than they both announced in the public press their belief that their client was insane. We are therefore privileged to wonder why they were so reticent on the subject when the case was still before the jury.

From this point of view we venture to predict that this case will always be looked upon as somewhat of an anomaly. It is certainly without precedent in this country for counsel for a prisoner to entertain a firm belief in that prisoner's insanity, and yet to put no witness on the stand in support of that belief. In fact this trial was marked by rather an apologetic attitude on the part of the learned counsel for the defence, which was hardly in keep-

ing with the traditions of the bar. It was Erskine's boast, in the case of Hadfield, that it was his privilege to defend the accused, who was "covered all over with the armor of the law." He based that defence on the prisoner's insanity, but he did not wait to proclaim his belief in that insanity until after the close of the trial. We speak simply in the interests of medical jurisprudence, and we cannot help but feel that the learned counsel have rather spoiled a fine situation by speaking as they did out of court.

As to the prisoner's mental state, we do not presume to raise a doubt other than that raised by his own lawyers. The experts who examined the accused were not put on the stand, and the inference is that either they were not wanted or that they had nothing to say.

The trial of the case was dignified, solemn and expeditious. The American public is to be congratulated that there was no repetition of the scenes that disgraced the trial of Guiteau. The medical profession, on the whole, is perhaps just as well satisfied that its services were not required in the prisoner's behalf.

Erskine's Defence of Hadfield.—In all the records of medical jurisprudence there is probably not a more important utterance than Erskine's speech for James Hadfield in the court of King's Bench, on a trial at bar. The case had some remarkable resemblances (as pointed out by a writer in the *New York Evening Post*) to that of the assassin Czolgosz, but in many respects it was most unlike it. Hadfield was indicted for shooting at King George III in Drury Lane Theatre, and was brought to trial in April 1800. He had fortunately missed his mark, but according to the English law, his offense was treason and his life was the forfeit. Erskine, then at the height of his fame as the leader of the English bar, was appointed by the court as counsel for the well-nigh defenceless wretch, and based his case entirely on the allegation of delusional insanity. In the opening sentence of his address to the jury he claimed that the duty imposed upon him by the court was a privilege. When we consider the state of public opinion in Great Britain one

hundred years ago with reference to the atrocity of an attempt to assassinate the King, and the general ignorance and perversity, both lay and professional, on the subject of insanity, we may well concede that Erskine's task was such a one as nobody but a legal Hercules could have brought to a successful conclusion.

Hadfield had been a soldier, and in the war in Flanders had received, in the midst of a desperate charge, a series of frightful wounds, one of which had penetrated the brain. His life was saved as by a miracle, but he never recovered his mental health, and deteriorated into a state of delusional insanity. He believed that, like the Savior, he was called upon to sacrifice his life, and under this delusion he fired upon the King.

The difficulty which Erskine had to encounter was to establish the validity of this defence against the antiquated and irrational definitions of insanity as expounded by the English law—definitions which are still too much in evidence in some of our American courts. This task he accomplished in a masterly oration, which even to this day leaves little to be criticised by the most advanced alienist. For its day, and for the circumstances, it was a revelation, and must always remain a landmark of one of the most important advances in the medical jurisprudence of insanity. The court at first had been much against the accused, but it was won over by the logic and eloquence of Lord Erskine, and finally ordered the prisoner's acquittal.

Hadfield's case differed entirely from that of Czolgosz in the radical fact that the prisoner had a good defence. But even so, it would be interesting to speculate as to what would have been the issue if Hadfield had succeeded in killing the King. We fear that in that case even the eloquence of Erskine would not have saved him.

Injuries of the Pancreas.—The pancreas is seldom seriously injured without other and more important viscera being involved. It is encompassed by important structures, many of which are vital. Many years ago its function was supposed to be that of a buffer for the protection of the large vessels lying behind it. One could conceive of a penetrating wound properly thrust below the kidney which might injure the pancreas alone, but we have never read the report of such a case. Uncomplicated rupture does not occur (Treves). That partial laceration or bruising without implication of the neighboring structures may occur after an abdominal contusion, giving rise to but transient discomfort, is demonstrated by pancreatic scars which have been disclosed after death. Robson says the pancreatic tissue is comparatively soft in consistence and easily

bruised, so that, although it is placed in the most favorable position for protection from direct injury, yet a slight injury takes more effect on it than on many firmer organs. We know how often slight hemorrhages occur after blows and falls in those individuals with apoplectic arteries or with pancreatic congestion due to interference with the venous return. The pancreas has been and is a laggard in surgery as well as in medicine. Much of this is due to its central position and to the difficulty of diagnosis. Abdominal injuries, be they wounds or contusions, are not subjected to operation because the pancreas is afflicted, but to anticipate or combat peritonitis and to check hemorrhage. A sterile stiletto puncture would not be followed by serious consequences unless a large artery were severed. The effect of a high velocity bullet with an adamant covering would probably be slight. A soft-nosed bullet with a low velocity would produce a ragged, contused laceration with a greater tendency to hemorrhage or sloughing. Ruptured pancreas is rapidly fatal from hemorrhage. Gangrene or suppuration may ensue. There are a number of traumatic pancreatic cysts on record. Some believe that many of these cysts are really collections of blood and pancreatic fluid in the lesser peritoneal cavity. Acute and chronic pancreatitis may follow contusions. The escape of sterile pancreatic juice into the peritoneal cavity does not necessarily mean peritonitis. When it escapes externally through a fistula it digests the skin, but it is probably absorbed rapidly from the peritoneal cavity or remains to form a cyst.

In all penetrating wounds of the abdomen laparotomy should be performed, not even excepting those produced by such weapons as the Mauser and Lee-Metford rifles, providing efficient facilities be at hand. On the field the expectant treatment of rifle wounds has proved to be safer, but this, we fear, may lead some to defer exploration in civil practice until symptoms of peritonitis appear. If on exploration the pancreas be found injured, hemostasis and cleansing are indicated. Should a portion of the organ protrude from a wound in the parietes it may be washed, reduced and sutured in place or the herniated portion may be excised. When the gland is ruptured or extensively lacerated, the blood vessels may be ligated and the rent sutured. More commonly gauze tamponage will be indicated because it is more quickly applied. A devitalized section of the gland or a crushed tail may be removed between ligatures. Operations on the head are limited to partial excision with the preservation of the common duct. Complete extirpation has been successfully accomplished in dogs but never in the human subject. In Senn's experiments the animals

died from hemorrhage, shock, peritonitis, gangrene of the duodenum, and marasmus. As long ago as 1682 Brunner noticed that dogs thrived after partial removal of the organ. It is asserted by some that diabetes will follow total pancreatectomy. That the other digestive organs may assume the work of the pancreas is proven by closure of the duct by disease or artificial means.

Hemolysis and Immunity.—The last few years witnessed revelations pregnant with results which it is a pleasure to contemplate. One by one the laboratory workers approach the obscure subject through different channels, coming nearer and nearer to a satisfactory solution of the difficult problems. Immunity against bacteria no longer stands alone among the phenomena surrounding cell-life; it finds its correlation in hemolysis and cytolysis. Bacterial toxins are identical with hemotoxins and cytotoxins, for the simple reason that the bacterial cell, like any other, possesses secretions which, while physiological as far as the bacterium itself is concerned, may be destructive to the life of other cells with which it comes in contact and is compelled to wage a war for existence. It is probable that the same law underlying the formation of the protective venoms in reptiles and insects also operates in the case of toxins. The first successful transfusion of blood from a goat into a human being performed by Deny's in 1667 was soon followed by others with less favorable results. It was finally learned that the blood of one species of animal cannot serve for transfusion into the blood current of an animal belonging to another species; it is either itself destroyed in the foreign organism or leads to destruction of the blood of the host, in other words, foreign blood is poisonous. The degree of toxicity is variable. Those near each other in the animal scale possess a blood of lesser toxicity for each other, as for instance, a rabbit and guinea pig. On the other hand the blood of birds and snakes is very poisonous to mammalia, while the blood of some fish, as the common eel, is such a virulent poison that 0.1 c.c. of the serum or whole blood is sufficient to kill by subcutaneous injection a large rabbit in 3 to 5 minutes. Repeated injections of smaller doses will bring about cachexia and finally death.

However, by careful injections of the blood of the eel into other animals Tshistovitch (*Bolnitchnaia Gazeta Botkina*, Vol. X, No. 19) succeeded in producing immunity in the same manner as it is produced in cases of vegetable or bacterial poisons. One of the remarkable phenomena accompanying immunization is the property acquired by the serum of the immunized animal to agglutinate the red blood corpuscles of the defibrinated blood of the eel.

Bordet (*Annales de l'Inst. Pasteur*, 1898) was the first to observe the agglutination of the red blood corpuscles of a rabbit by the serum of a guinea pig which received the blood of the former into the abdominal cavity or subcutaneously. This phenomenon he showed to be peculiar to almost all kinds of blood. If a guinea pig or rabbit receives injections of the blood of a hen, dove, horse, etc., the serum of the former will agglutinate the blood corpuscles of the latter. The agglutination takes place after 3 to 4 injections, the corpuscles coming together and forming islands with clear spaces between; soon the hemoglobin is dissolved out and the corpuscles disintegrate. This phenomenon is identical with that observed in agglutination of bacteria by the serum of animals suffering from diseases produced by them. Like in the case of bacterial infection, the agglutination of the red blood corpuscles can be made specific, *i. e.*, only that blood will be agglutinated which was received by the immunized animal. The specific substance which agglutinates and destroys the red blood corpuscles of the foreign blood consists, according to Bordet of two elements: "alexine" and "substance sensibilisatrice"; the former is a normal constituent of every blood, the latter formed only after the injection of the foreign blood. The "substance sensibilisatrice" so affects the red blood corpuscles that they are readily seized and destroyed by the "alexine". Ehrlich and Morgenroth call the alexine "complement" or "addiment" and the substance sensibilisatrice—"Immunkörper" or, *Zwischenkörper*". According to these authors, the red blood corpuscles of the foreign blood extract the "Immunkörper" with which they enter into a chemical union. London (*Archives des sciences biologiques*, Vol. VIII, Nos. 3 to 4), repeated the work of the predecessors and by special methods instituted a series of elaborate experiments elucidating every phase of this interesting phenomenon. He departs from the usual terminology by substituting the term "desmon" for "Immunkörper". The former (derived from the greek word meaning to bind) he considers more appropriate and in accord with our present knowledge. Space does not permit us to review even briefly the many interesting experiments, and we shall give only some of the summaries of the results. The author found that physiological hemolysin is composed of alexine and desmon. The former is either of alkaline or acid reaction and is destroyed by a temperature of 55 C.; the latter is neutral in reaction and withstands high temperature. The normal blood contains various hemolysins, or at least material for their formation. These differ from each other by their specific action on different blood corpuscles and, accordingly, in

the nature of the alexine and desmon. The hemolysins of related animals, as the cat and dog, are similar in their action and composition. In artificial hemolysis only the desmon is produced which differs from the physiological desmon only in the fact that it gives a stronger hemolysin with a weaker alexine. Otherwise there is no difference between artificial and physiological hemolysin. Ehrlich's lateral chain theory is contraverted by the fact that both isolysin and autospersmolysin may be artificially produced. According to this theory artificial hemolysin or antitoxin is only an intensified physiological product. If such were the case it would be impossible to explain the formation of isolysin and autolysin which are never found in the normal blood. Furthermore, Metchnikoff found that by the proper method of immunization he could produce spermatotoxin in animals devoid of testicles, and consequently spermatozooids, which according to Ehrlich would be indispensable to the formation of spermatotoxin. Buchner's theory on the other hand, fails to explain the physiological hemolysins. Experiments performed by the author have shown that (1) the spleen plays the chief role in the formation of artificial hemolysin; (2) that the formation of hemolysin is connected with the function of the spleen and not with the mere presence of its cellular elements in the abdominal cavity, and (3) the spleen has no effect on the hemolysin already formed. On the ground of these observations the author presupposes the following mechanism of the formation of artificial hemolysins: The blood elements entering the body of the animal subjected to immunization undergo disintegration. The products enter the blood current and are retained in the spleen where they undergo a peculiar transformation and again enter the blood current. Here they come in contact with the various desmons among which is also the specific desmon produced under the stimulation of the blood which is used for injection. The special products then enter into chemical combination with the specific desmon which becomes modified in a certain direction. In acting on the red blood corpuscles, the desmon agglutinates them, while the alexin produces their disintegration. In formulating his theory of immunity, the author expresses as his opinion that the formation of hemolysins (or antitoxins) is intimately connected with the functions of the cells (of the spleen). Once the hemolysins formed, the battle against toxic agents is transferred—a purely physico-chemical ground. The cellulo-humoral theory, therefore, is the only one possessing the elements of a satisfactory explanation.

Medical Society of the State of Pennsylvania.—The fifty-first annual meeting of the Medical Society of the State of Pennsylvania, just held at Philadelphia, was in every respect a most gratifying success. The registration was the largest in the history of the Society, and the meetings were well attended by appreciative listeners. The program was full—even to overflowing, and in this connection the suggestion seems not inopportune that it might be better to have a smaller number of papers to be selected by the Committee on Scientific Business from among those proffered or solicited by the committee from distinguished members or original investigators or authoritative writers, in order that a little more time be given to each communication and reasonable discussion be permitted. In this way another suggestion that has been made might also be adopted, namely the invitation of distinguished physicians from other States to present papers. The social entertainment of the visiting members of the society was likewise well and generously provided for. Some of the receptions were upon a really munificent scale, and the visitors generally have gone away with a sense of satisfaction with the scientific program and a feeling of gratitude for the cordial hospitality that has been shown them. The thanks of the members are due to the officers of the meeting, and particularly the Committee on Arrangements, to whose efforts the success of the meeting must be largely credited. Dr. Davis presided with eminent grace and ability and his admirable address, which it is feared was not heard by as many as could be wished, on account of the noise made by parading bands of music on the street, will surely be read with pleasure and profit when published.

In Dr. Ball, of Lock Haven, the society will have a worthy successor to Dr. Davis, and we hope that the meeting at Allentown in 1902 will be not less successful than that which has just been concluded. The Committee to Suggest Changes in the By-laws presented a long report, which was not read, but is to be published and distributed, and which is intended to bring the organization of the society into harmony with the recent reorganization of the American Medical Association.

It is expected that the Medical Society of the State of Pennsylvania will be entitled to eight members in the House of Delegates of the American Medical Association.

The Continuous and Remittent Fevers Found in Greece.—But four classes of fevers are found in Greece, according to Dr. Spiridon Kanellis of Athens, (*Medicine Moderne*, June 5, 1901, No. 23). The first class consists of those common fevers, remittent, or continued, auto-infectious, of gastrointestinal origin, which last from one to three weeks, seen especially in the warm weather. Typhoid fever forms the second class. The third class comprises all the forms of malarial fever, the gastric, the bilious, the gastro-bilious, and the pseudo-typhoid. In the last group are the many cases in which two or more of the above mentioned types occur together, the mixed or complicated fevers. [M. O.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

University of Pennsylvania Medical School.—The Medical Department of the University of Pennsylvania opened its 136th annual session on Tuesday, October 1, 1901, at noon. Mr. C. C. Harrison, provost of the University, addressed the students.

Jefferson Medical College.—On Tuesday evening, October 1, 1901, the Jefferson Medical College opened its 77th annual session. Dr. J. Chalmers Da Costa, professor of clinical surgery, delivered the introductory address.

Medico-Chirurgical College.—The opening exercises of the Medico-Chirurgical College were held Tuesday evening, October 1, 1901. The inaugural address was made by Dr. John C. Heisler, professor of anatomy.

Recent Dental Anatomy.—A lecture was given last week before the students of the dental school of the University of Pennsylvania, upon some recent studies in the anatomy of the teeth and jaws, by Dr. Willoughby D. Miller, professor in the dental department of the University of Berlin. It is announced that Dr. Miller will receive the degree of Sc. D. at the next commencement exercises of the University of Pennsylvania.

Bequests.—By the will of the late Helen M. Parker, of West Philadelphia, the Women's Pennsylvania Society for the Prevention of Cruelty to Animals receives the sum of \$10,000 to be used for the erection of fountains for horses and dogs and \$1,000 for the general purposes of the organization. \$5,000 is also left to the Home for Incurables to endow a bed in her name. Should her son, to whom the residuary estate is left, die without issue, \$25,000 more will go to the Home for Incurables, and the rest to the Society for the Prevention of Cruelty to Animals.

NEW JERSEY.

McKinley's Memorial Fund.—The people of Trenton are much interested in a McKinley memorial. A sum of money is to be raised by small popular subscriptions for the erection of a wing to the Mercer Hospital to be named in memory of the late president. Several hundred dollars have already been contributed.

A New Medical Society.—A new medical society has been organized at Perth Amboy, N. J. This is the first society of the kind in this city. The officers are Dr. J. S. Wilson, president; Dr. H. M. Brace, vice-president; Dr. F. C. Henry, secretary; Dr. W. E. Ramsay, treasurer.

Dr. William S. Baldwin Paralyzed.—On September 25th, Dr. William S. Baldwin, of New Brunswick, one of the managers of the State Hospital at Trenton, and member of the committee investigating the affairs of the institution, while stepping from a carriage at the asylum to attend the investigation, was stricken with paralysis. Dr. Baldwin reeled and fell to the ground in the presence of his associates, who bore him to a room in the institution, where he was attended by the house physicians. His recovery is yet very doubtful. The investigation was not resumed on account of Dr. Baldwin's affliction. Dr. Baldwin is seventy-seven years of age, and is one of the oldest practitioners in New Jersey; he has never held public office except as manager of the asylum. He was one of the physicians of Rutgers College, in New Brunswick while Governor Voorhees was a student there.

NEW YORK.

Food Adulterants.—One of the most striking features of the exhibit of the Department of Agriculture at Buffalo is a collection of silks dyed with food adulterants. One piece of silk is a brilliant red from a substance called "rosaline," used for coloring meats, such as corned beef and sausage. A yard of pink is tinted with dye from preserved cherries and another yard of salmon hue owes its beauty to currant jam. Various kinds of jellies give other colors; there is a fine purple from port wine, a magenta from burgundy, a light red from tomato catsup and a pretty yellow from soda water flavoring.—*Exchange.*

The Medical Society of the State of New York will hold a semi-annual meeting in Hosack Hall, New York Academy of Medicine, 17 West Forty-third street, New York City, October 15th and 16th, 1901.

The Intradural Injection of Tetanus Antitoxin.—The successful use of intradural injections of antitetanic serum, in a boy of fourteen, is announced by Drs. Kinear and Hoyt, of St. Catherine's Hospital, Brooklyn, N. Y.

The American Public Health Association.—At the meeting of the American Public Health Association held in Buffalo, September 16-20, the following officers were elected for the ensuing year: President, Dr. Henry D. Holton, Brattleboro, Vt.; 1st Vice-President, Dr. Walter Reed, U. S. Army; 2d Vice-President, Dr. Jesus Chico, Guanaquato, Mexico, and Treasurer, Dr. Frank W. Wright, New Haven, Conn. The meeting next year will be held at New Orleans.

The Milk in New York.—The Milk Commission of the New York County Medical Society, which was appointed in January, 1900, made its report last week. The Commission found the milk supply of the city very good from a chemical point of view, but the amount of bacteria obtained from it was alarming.

Electrocution.—This method of exterminating criminals was first suggested by Dr. A. P. Southwick, of Buffalo, in 1875. It was only ten years later that Governor Hill of New York permitted the substitution of the electric chair for the gallows. In 1888 an act was passed directing the execution of capital criminals by the electric chair, and in 1890, electrocution was first attempted upon a murderer named Kemmler, at Auburn, N. Y. The chair consists of an adjustable head-rest, in which the head electrode is fixed, binding straps, and another electrode, which,

penetrating the back of the chair, is applied to the lower spine. The electrodes connect with a coil leading from the dynamo, the voltage reaching as high as 2000. The chair is fastened to the floor, its feet being well insulated. Death occurs in from 10 to 20 seconds, and is thus almost instantaneous. It is in this chair that Czolgosz will meet his death during the last days of October.

NEW ENGLAND.

Typhoid Fever in Nahant, Mass.—Almost 20 cases of typhoid fever have occurred among the families who have spent the summer in Nahant. Five of them are under treatment at the Lynn Hospital. The remainder are either being treated in their summer homes in Nahant, or have been removed to the hospitals in Boston. A number of them are at the Massachusetts General Hospital. As near as can be learned, the sickness is due to the milk supply which has been furnished by a milkman said to belong to Lynn. A representative of the State Board of Health visited Nahant, and afterward visited the patients at the Lynn Hospital, but if he reached any definite conclusion as to the cause of the trouble, he did not make it known. The town of Nahant gets its water supply through the metropolitan system. No deaths have been reported so far.

WESTERN STATES.

Nicholas Senn Prize Medal.—The committee on the Senn Medal beg leave to call attention to the following conditions governing the competition for this medal for 1902: 1. A gold medal of suitable design is to be conferred upon the member of the American Medical Association who shall present the best essay upon some surgical subject. 2. This medal will be known as the Nicholas Senn Prize Medal. 3. The award will be made under the following conditions: *a.* The name of the author of each competing essay shall be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. All successful essays become the property of the Association. *c.* The medal shall be conferred and honorable mention made of the two other essays considered worthy of distinction, at a general meeting of the Association. *d.* The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. *e.* The competition for the medal will be closed three months before the next annual meeting of the American Medical Association, and no essays will be received after March 1, 1902. Communications may be addressed to any member of the committee, consisting of the following: Dr. Herbert L. Burrell, 22 Newbury street, Boston, Mass.; Dr. Edward Martin, 415 South Fifteenth street, Philadelphia, Pa.; Dr. Charles H. Mayo, Rochester, Minn.

Oberlin College.—At the conclusion of the dedicatory exercises of the new Severance Chemical Laboratory at Oberlin College, September 26th, Mr. Lewis H. Severance, of New York City, the donor, handed to President Harrows a slip of paper upon which was the announcement of his gift of \$44,000 as endowment for the chair of chemistry in the college.

The Shelby Medal.—Dr. W. D. Shelby, captain and assistant surgeon of the United States army in the Philippines, has given Hanover (Ind.) College a fund as a memorial to his father, who was formerly a student in the college. From the proceeds of this fund a medal will be struck annually for the best work in scientific studies.

Sterilization of Lead Pencils.—The news comes from Chicago that all lead pencils used by the pupils of the Chicago public schools will in the future be sterilized to prevent the dissemination of diseased germs.

The Wyoming State Medical Society held its fourth annual meeting at Evanston, October 8-9, 1901.

Idaho State Medical Society.—The ninth annual meeting of the Idaho State Medical Society was held at Pocatello, October 3-4, 1901.

SOUTHERN STATES.

A Large Dose of Antitoxin.—Dr. Ward of Baltimore recently reported two cases of tetanus in horses, treated with tetanus antitoxin. In one of the horses five bottles of antitoxin were injected. One bottle of antitetanic serum was injected at a time, and this was repeated every three days. Slight improvement was not noted until after the third bottle had been injected. The only other drug given was the fluid extract of belladonna, injected into the muscles of the mouth to prevent trismus. Both horses recovered rapidly.

Smallpox in Maryland.—Just east of Federalsburg, Md., almost upon the line dividing Delaware from Maryland, sixteen cases of variola have been discovered. On this account, the big Epworth League Convention, announced for October 23, has been indefinitely postponed. The circus, which had been scheduled to arrive next week, has also been notified not to come.

Public School Inspection.—Owing to the recent misunderstandings between the school trustees and some of the teachers regarding the sanitary arrangements of the public schools, the Board of Health of the city of Richmond, Va., are at present making a complete inspection of all the buildings, 18 in number.

CANADA.

(From Our Special Correspondent.)

Royalty at McGill.—When the Duke and Duchess of Cornwall and York paid their visit to Montreal, His Royal Highness performed the ceremony of declaring the new medical buildings of McGill University open. Dr. Craik, Dean of the Medical Faculty, read an address in which much interesting information was contained regarding this department of the University. This medical school has been in active operation since 1824, more than three-quarters of a century; for the first five years the school was known as the Montreal Medical Institution. In 1829 it was incorporated with McGill University and became its medical department. When the school opened in 1824, there were twenty-five students in attendance. At the time of its incorporation with the University, the number had only reached thirty. Twenty years later, in 1849, the number of students was forty-four. In 1889, when the faculty was in its sixtieth year, the number had grown to two hundred and twenty-seven; while last year, which was its seventy-second year, the number was four hundred and ninety. Formerly the provinces of Quebec and Ontario supplied nine-tenths of all the medical students at McGill; now, forty per cent. come from places outside of these provinces. Other students come from all the other provinces of the Dominion, from Newfoundland, from the United States (ten per cent. of the whole number), from the West Indies, from the British Islands, and last year two students came from China, and one from Japan. This great increase in the number of students has of course necessitated a corresponding increase in the teaching staff. Seventy-seven years ago the faculty was composed of but four members. Now it contains over seventy.

Christian Science and Dowieism are not going to be allowed by the authorities to meander as they please in this Dominion. A Dowieite in British Columbia has recently been convicted of manslaughter for refusing medical attendance to his two children, who died from diphtheria under the "silent" treatment. While they are "after 'em" in the West, they are not going to be behind hand in the East. The case of a father in Toronto who refused to supply medical attention to his child for the same disease was up before a Police Magistrate here last week; the result was that the father was committed to stand trial at the coming sessions. During the progress of the preliminary inquiry, the Crown Attorney produced Mrs. Eddy's book and proceeded to read extracts. He stated that he had no hesitation in saying that Christian Science as set out in Mrs. Eddy's book was the most damnable blasphemy he had ever read. While these extracts were being read out in court, the Magistrate interjected: is that woman still at large? "Yes," replied the Crown Attorney. "She got this message from God copyrighted." "Oh, that shows she's sane enough in one respect," replied the Police Magistrate. In the opinion of the two officials, this work must be stopped.

The Provincial Board of Health Report of the Province of Ontario which has just been issued is the nineteenth

annual report of that Department. It gives the death rate in the province for the year 1900 as 11.9 per thousand, 25,382 deaths having been reported in a total population of 2,302,705. Only 93 per cent. of this population reported deaths. Scarlet fever claimed 133; diphtheria 486; measles 93; whooping cough 121; typhoid 550; consumption 2,360. The report of the bacteriologist of the work done in the laboratory shows that in all, there were examined 1,669 specimens. These were divided as follows: Sputum, 703; exudate in diphtheria, 526; blood in typhoid fever, 221; water, 194; water for chemical examination, 33; sewage, 7; lee, two; milk, four; meat—tuberculous, four; actinomyces, 2; anthrax, 4; unknown, two.

Another Centenarian.—The death of a centenarian is reported from the county of Wentworth, Ontario. He had reached 103 years and 7 months.

Smallpox has broken out in Ottawa and is regarded as very serious. The compulsory vaccination by-law is being enforced in the schools. A case has developed in the census bureau and Dr. Montizambert has vaccinated all the employees and officials of that department. Owing to severe criticism, Dr. Robillard, who has been health officer for over twenty years, has tendered his resignation.

Anthrax in Canada.—A very severe outbreak of anthrax is reported among sheep in the Canadian Northwest. Over four thousand of these have died on one ranch alone, and deaths have been reported amongst cattle and horses. The disease was brought into that section by shepherders from Australia. Strict and immediate quarantine was enforced and the outbreak is now said to be held in check.

Quebec College of Physicians and Surgeons.—The following officers have been elected in the Quebec College of Physicians and Surgeons for the ensuing year: President, Dr. Lachapelle, Montreal; vice-presidents, Dr. Vallée, Quebec, and Dr. Craik, Montreal; registrar, Dr. Marsolais, Montreal; treasurer, Dr. Jobin, Quebec; secretaries, Dr. McDonald, Montreal and Dr. Paquin, Quebec.

Trinity Medical College, Toronto, opened for the session of 1901-1902 on the afternoon of September 25th. Dr. Charles Sheard delivered the opening lecture. There were forty-eight first year students registered, the largest class registered on the first day in twenty years.

The Amalgamation of the Toronto Societies.—An effort is being made to amalgamate the different local medical societies of Toronto, to form a strong branch of the British Medical Association.

MISCELLANY.

The President's Assassin Sane.—Through an oversight, the statement appeared in the last issue of the *Philadelphia Medical Journal* that Czolgosz, the assassin of President McKinley, had been judged insane by Drs. Allan McLane Hamilton, Carlos T. McDonald and others. These distinguished alienists, after a thorough examination, all agreed that Czolgosz was perfectly sane.

President McKinley's Interest in the Public Health.—Official announcement to the Marine Hospital Service of the death of the late President McKinley is made in the Public Health Report just issued by the Surgeon-General. It says that "to the admiration and love for President McKinley, inspired by his statesmanship, manhood, and personal qualities, should be added a just appreciation of his prompt response to requests for action in public health matters," and recounts many executive orders issued for the purpose of insuring public safety. Among other things it mentions that when the yellow fever appeared in the National Soldiers' home at Hampton, Va., in 1899, he showed extreme solicitude for the veterans and requested a daily report on the progress of the disease and the success of the measures to check it.
